Table of Contents

What is Amazon RDS?	1
Overview	1
Amazon EC2 and on-premises databases	1
Amazon RDS and Amazon EC2	2
Amazon RDS Custom for Oracle and Microsoft SQL Server	3
Amazon RDS on AWS Outposts	3
DB instances	3
DB engines	4
DB instance classes	4
DB instance storage	4
Amazon Virtual Private Cloud (Amazon VPC)	5
AWS Regions and Availability Zones	5
Security	5
Monitoring an Amazon RDS DB instance	5
How to work with Amazon RDS	5
AWS Management Console	6
Command line interface	6
Programming with Amazon RDS	6
How you are charged for Amazon RDS	6
What's next?	6
Getting started	6
Topics specific to database engines	6
DB instances	8
DB instance classes	10
DB instance class types	10
Supported DB engines	12
Determining DB instance class support in AWS Regions	39
Changing your DB instance class	42
Configuring the processor	42
Hardware specifications	55
DB instance storage	64
Storage types	64
General Purpose SSD storage	64
Provisioned IOPS storage	66
Comparing SSD storage types	68
Magnetic storage	68
Monitoring storage performance	69
Factors that affect storage performance	69
Regions, Availability Zones, and Local Zones	72
AWS Regions	73
Availability Zones	75
Local Zones	76
Supported Amazon RDS features by Region and engine	77
Table conventions	77
Feature quick reference	77
Cross-Region automated backups	78
Cross-Region read replicas	83
Database activity streams	85
Dual-stack mode	88
Export snapshots to S3	95
IAM database authentication	99
Kerberos authentication	101
Multi-AZ DB clusters	107
Performance Insights	110

RDS Custom	110
Amazon RDS Proxy	114
Engine-native features	120
Multi-AZ deployments	121
Multi-AZ DB instance deployments	122
Multi-AZ DB cluster deployments	127
DB instance billing for Amazon RDS	138
On-Demand DB instances	139
Reserved DB instances	140
Setting up	148
Sign up for an AWS account	148
Create an administrative user	148
Create IAM user access keys	149
Determine requirements	150
Provide access to your DB instance	151
Getting started	153
Creating a MariaDB DB instance and connecting to a database	154
Creating a MariaDB DB instance	154
Connecting to a database on a DB instance running MariaDB	158
Deleting a DB instance	161
Creating a SQL Server DB instance and connecting to it	162
Creating a sample SQL Server DB instance	162
Connecting to your sample DB instance	166
Exploring your sample DB instance	169
Deleting your sample DB instance	170
Creating a MySQL DB instance and connecting to a database	172
Creating a MySQL DB instance	172
Connecting to a database on a DB instance running MySQL	176
Deleting a DB instance	179
Creating an Oracle DB instance and connecting to a database	180
Creating a sample Oracle DB instance	180
Connecting to your sample DB instance	184
Deleting your sample DB instance	186
Creating a PostgreSQL DB instance and connecting to a database	187
Creating a PostgreSQL DB instance	187
Connecting to a PostgreSQL DB instance	191
Deleting a DB instance	197
Tutorial: Create a web server and an Amazon RDS DB instance	198
Launch an EC2 instance	199
Create a DB instance	203
Install a web server	207
Tutorials and sample code	214
Tutorials in this guide	214
Tutorials in other AWS guides	215
Tutorials and sample code in GitHub	215
Best practices for Amazon RDS	216
Amazon RDS basic operational guidelines	216
DB instance RAM recommendations	217
Using Enhanced Monitoring to identify operating system issues	217
Using metrics to identify performance issues	217
Viewing performance metrics	217
Evaluating performance metrics	220
Tuning queries	221
Best practices for working with MySQL	222
Table size	222
Number of tables	222
Storage engine	223

Best practices for working with MariaDB	223
Table size	223
Number of tables	224
Storage engine	224
Best practices for working with Oracle	224
Best practices for working with PostgreSQL	224
Loading data into a PostgreSQL DB instance	225
Working with the PostgreSQL autovacuum feature	225
Amazon RDS for PostgreSQL best practices video	226
Best practices for working with SQL Server	226
Amazon RDS for SQL Server best practices video	227
Working with DB parameter groups	227
Best practices for automating DB instance creation	227
Amazon RDS new features and best practices presentation video	228
Configuring a DB instance	229
Creating a DB instance	230
Prerequisites	230
Creating a DB instance	233
Available settings	237
Creating a Multi-AZ DB cluster	252
Prerequisites	252
Creating a DB cluster	255
Available settings	258
Nonapplicable settings	265
Creating resources with AWS CloudFormation	266
RDS and AWS CloudFormation templates	266
Learn more about AWS CloudFormation	266
Connecting to a DB instance	267
Finding the connection information	267
Database authentication options	270
Encrypted connections	271
Scenarios for accessing a DB instance	271
Connecting to a DB instance running a specific DB engine	271
Managing connections with RDS Proxy	272
Working with option groups	273
Option groups overview	273
Creating an option group	274
Copying an option group	276
Adding an option to an option group	277
Listing the options and option settings for an option group	281
Modifying an option setting	282
Removing an option from an option group	285
Deleting an option group	286
Working with parameter groups	289
Working with DB parameter groups	291
Working with DB cluster parameter groups	302
Comparing parameter groups	310
Specifying DB parameters	310
Managing a DB instance	316
Stopping a DB instance	317
Benefits	318
Limitations	318
Option and parameter group considerations	318
Public IP address	318
Stopping a DB instance	318
Starting a DB instance	320
Connecting an EC2 instance	321

Overview	321
Connecting an EC2 instance	324
Viewing connecting compute resources	326
Modifying a DB instance	327
Apply Immediately setting	328
Available settings	328
Modifying a Multi-AZ DB cluster	341
Apply Immediately setting	342
Available settings	342
Nonapplicable settings	348
Maintaining a DB instance	350
Viewing pending maintenance	350
Applying updates	352
Maintenance for Multi-AZ deployments	353
The maintenance window	354
Adjusting the maintenance window for a DB instance	355
Working with operating system updates	356
Upgrading the engine version	360
Manually upgrading the engine version	360
Automatically upgrading the minor engine version	362
Renaming a DB instance	364
Renaming to replace an existing DB instance	364
Rebooting a DB instance	366
Rebooting Multi-AZ DB clusters	368
Working with read replicas	370
Overview	372
Creating a read replica	375
Promoting a read replica	377
Monitoring read replication	380
Cross-Region read replicas	383
Tagging RDS resources	392
Overview	392
Using tags for access control with IAM	393
Using tags to produce detailed billing reports	393
Adding, listing, and removing tags	394
Using the AWS Tag Editor	396
Copying tags to DB instance snapshots	396
Tutorial: Use tags to specify which DB instances to stop	397
Enabling backups	399
Working with ARNs	402
Constructing an ARN	402
Getting an existing ARN	406
Working with storage	410
Increasing DB instance storage capacity	410
Managing capacity automatically with storage autoscaling	412
Modifying Provisioned IOPS settings	416
I/O-intensive storage modifications	418
Modifying General Purpose (gp3) settings	418
Deleting a DB instance	421
Deletion protection	421
Final snapshots and retained backups	421
Deleting a DB instance	422
Deleting a Multi-AZ DB cluster	424
Backing up and restoring a DB instance	426
Working with backups	427
Backup storage	427
Backup window	428

Backup retention period	429
Enabling automated backups	429
Retaining automated backups	431
Deleting retained automated backups	433
Disabling automated backups	434
Using AWS Backup	435
Unsupported MySQL storage engines	435
Unsupported MariaDB storage engines	436
Cross-Region automated backups	437
Region and version availability	437
Source and destination AWS Region support	437
Enabling cross-Region automated backups	439
Finding information about replicated backups	441
Point-in-time recovery from a replicated backup	444
Stopping backup replication	445
Deleting replicated backups	446
Creating a DB snapshot	448
Creating a Multi-AZ DB cluster snapshot	450
Restoring from a DB snapshot	452
Parameter groups	452
Security groups	452
Option groups	453
Tagging	453
Microsoft SQL Server	453
Oracle Database	454
Restoring from a snapshot	454
Restoring from a snapshot to a Multi-AZ DB cluster	456
Copying a DB snapshot	458
Limitations	458
Snapshot retention	458
Copying shared snapshots	458
Handling encryption	459
Incremental snapshot copying	459
Cross-Region copying	460
Option groups	463
Parameter groups	463
Copying a DB snapshot	464
Sharing a DB snapshot	472
Sharing public snapshots	473
Sharing encrypted snapshots	474
Sharing a snapshot	476
Exporting DB snapshot data to Amazon S3	481
Region and version availability	481
Limitations	481
Overview of exporting snapshot data	482
Setting up access to an S3 bucket	483
Using a cross-account KMS key	485
Exporting a DB snapshot	486
Monitoring snapshot exports	489
Canceling a snapshot export	490
Failure messages	491
Troubleshooting PostgreSQL permissions errors	492
File naming convention	492
Data conversion	493
Point-in-time recovery	499
Restoring a Multi-AZ DB cluster to a specified time	502
Deleting a DB snapshot	505

Deleting a DB snapshot	505
Tutorial: Restore a DB instance from a DB snapshot	507
Restoring a DB instance from a DB snapshot	507
Monitoring metrics in a DB instance	510
Overview of monitoring	511
Monitoring plan	511
Performance baseline	511
Performance guidelines	511
Monitoring tools	512
Viewing instance status and recommendations	515
Viewing Amazon RDS DB instance status	516
Viewing Amazon RDS recommendations	520
Viewing metrics in the Amazon RDS console	525
Monitoring RDS with CloudWatch	528
Overview of Amazon RDS and Amazon CloudWatch	529
Viewing CloudWatch metrics	530
Creating CloudWatch alarms	535
Tutorial: Creating a CloudWatch alarm for DB cluster replica lag	536
Monitoring DB load with Performance Insights	543
Overview of Performance Insights	543
Turning Performance Insights on and off	549
Turning on the Performance Schema for MariaDB or MySQL	553
Performance Insights policies	556
Analyzing metrics with the Performance Insights dashboard	559
Retrieving metrics with the Performance Insights API	584
Logging Performance Insights calls using AWS CloudTrail	598
Monitoring the OS with Enhanced Monitoring	600
Overview of Enhanced Monitoring	600
Setting up and enabling Enhanced Monitoring	601
Viewing OS metrics in the RDS console	605
Viewing OS metrics using CloudWatch Logs	608
RDS metrics reference	609
CloudWatch metrics for RDS	609
CloudWatch dimensions for RDS	616
CloudWatch metrics for Performance Insights	617
Counter metrics for Performance Insights	618
SQL statistics for Performance Insights	628
OS metrics in Enhanced Monitoring	633
Monitoring events, logs, and database activity streams	642
Viewing logs, events, and streams in the Amazon RDS console	642
Monitoring RDS events	646
Overview of events for Amazon RDS	646
Viewing Amazon RDS events	647
Working with Amazon RDS event notification	650
Creating a rule that triggers on an Amazon RDS event	664
Amazon RDS event categories and event messages	668
Monitoring RDS logs	680
Viewing and listing database log files	680
Downloading a database log file	681
Watching a database log file	682
Publishing to CloudWatch Logs	683
Reading log file contents using REST	685
MariaDB database log files	687
Microsoft SQL Server database log files	696
MySQL database log files	700
Oracle database log files	709
PostgreSQL database log files	716

Monitoring RDS API calls in CloudTrail	725
CloudTrail integration with Amazon RDS	725
Amazon RDS log file entries	725
Monitoring Oracle with Database Activity Streams	729
Overview	729
Configuring Oracle unified auditing	732
Starting a database activity stream	732
Modifying a database activity stream	734
Getting the activity stream status	736
Stopping a database activity stream	737
Monitoring activity streams	738
Managing access to activity streams	752
Working with Amazon RDS Custom	755
Database customization challenge	755
RDS Custom management model and benefits	756
Shared responsibility model	756
Key benefits of RDS Custom	758
RDS Custom architecture	758
VPC	759
Amazon S3	759
AWS CloudTrail	760
RDS Custom automation and monitoring	760
Security considerations for RDS Custom	762
Working with RDS Custom for Oracle	763
RDS Custom for Oracle workflow	763
RDS Custom for Oracle requirements and limitations	766
Setting up your RDS Custom for Oracle environment	768
Working with CEVs for RDS Custom for Oracle	781
Configuring an RDS Custom for Oracle DB instance	807
Managing an RDS Custom for Oracle DB instance	816
Working with RDS Custom for Oracle replicas	826
Backing up and restoring an RDS Custom for Oracle DB instance	831
Upgrading a DB instance for RDS Custom for Oracle	838
Working with RDS Custom for SQL Server	843
RDS Custom for SQL Server workflow	843
RDS Custom for SQL Server requirements and limitations	845
Setting up your RDS Custom for SQL Server environment	847
Creating and connecting to an RDS Custom for SQL Server DB instance	860
Managing an RDS Custom for SQL Server DB instance	868
Backing up and restoring an RDS Custom for SQL Server DB instance	877
Migrating an on-premises database to RDS Custom for SQL Server	885
Upgrading a DB instance for RDS Custom for SQL Server	888
Troubleshooting RDS Custom	889
Viewing RDS Custom events	889
Subscribing to event notifications	889
Troubleshooting CEV creation	890
Support perimeter and unsupported configurations	891
Fixing unsupported configurations	891
How Amazon RDS Custom replaces an impaired host	897
Troubleshooting RDS Custom for Oracle upgrade issues	899
Troubleshooting RDS Custom for Oracle replica promotion	900
Troubleshooting RDS Custom for Oracle replica creation	900
Working with RDS on AWS Outposts	902
Prerequisites	902
Support for Amazon RDS features	904
Supported DB instance classes	907
Customer-owned IP addresses	909

Using ColPs	909
Limitations	910
Multi-AZ deployments	911
Working with the shared responsibility model	911
Improving availability	911
Prerequisites	912
Working with API operations for Amazon EC2 permissions	913
Creating DB instances for RDS on Outposts	914
Considerations for restoring DB instances	920
Using RDS Proxy	921
Region and version availability	921
Quotas and limitations	921
RDS for MariaDB limitations	922
RDS for SQL Server limitations	923
MySQL limitations	923
PostgreSQL limitations	924
Planning where to use RDS Proxy	924
RDS Proxy concepts and terminology	925
Overview of RDS Proxy concepts	925
Connection pooling	926
Security	926
Failover	928
Transactions	928
Getting started with RDS Proxy	929
Setting up network prerequisites	929
Setting up database credentials in Secrets Manager	931
Setting up IAM policies	932
Creating an RDS Proxy	934
Viewing an RDS Proxy	938
Connecting through RDS Proxy	939
Managing an RDS Proxy	941
Modifying an RDS Proxy	942
Adding a database user	946
Changing database passwords	946
Configuring connection settings	946
Avoiding pinning	948
Deleting an RDS Proxy	952
Working with RDS Proxy endpoints	952
Overview of proxy endpoints	953
Reader endpoints	953
Accessing Aurora and RDS databases across VPCs	954
Creating a proxy endpoint	954
Viewing proxy endpoints	956
Modifying a proxy endpoint	957
Deleting a proxy endpoint	958
Limitations for proxy endpoints	959
Monitoring RDS Proxy with CloudWatch	959
Working with RDS Proxy events	964
RDS Proxy events	964
RDS Proxy examples	965
Troubleshooting RDS Proxy	967
Verifying connectivity for a proxy	967
Common issues and solutions	968
Using RDS Proxy with AWS CloudFormation	972
MariaDB on Amazon RDS	974
MariaDB feature support	975
MariaDB major versions	975

Supported storage engines	979
Cache warming	980
Features not supported	981
MariaDB versions	982
Supported MariaDB versions	982
MariaDB release calendar	983
MariaDB 10.3 end of life	984
MariaDB 10.2 end of life	984
Deprecated MariaDB versions	985
Connecting to a DB instance running MariaDB	986
Finding the connection information	986
Connecting from the MySQL command-line client (unencrypted)	989
Troubleshooting	990
Securing MariaDB connections	991
MariaDB security	991
Encrypting with SSL/TLS	992
Using new SSL/TLS certificates	994
Upgrading the MariaDB DB engine	998
Overview	998
Major version upgrades	999
Upgrading a MariaDB DB instance	1000
Automatic minor version upgrades	1000
Importing data into a MariaDB DB instance	1003
Importing data from an external database	1004
Importing data to a DB instance with reduced downtime	1006
Importing data from any source	1019
Working with MariaDB replication	1024
Working with MariaDB read replicas	1024
Configuring GTID-based replication with an external source instance	1034
Configuring binary log file position replication with an external source instance	1036
Options for MariaDB	1040
MariaDB Audit Plugin support	1040
Parameters for MariaDB	1043
Viewing MariaDB parameters	1043
MySQL parameters that aren't available	1044
Migrating data from a MySQL DB snapshot to a MariaDB DB instance	1046
Performing the migration	1046
Incompatibilities between MariaDB and MySQL	1048
MariaDB on Amazon RDS SQL reference	1049
mysql.rds_replica_status	1049
mysql.rds_set_external_master_gtid	1050
mysql.rds_kill_query_id	1052
Local time zone	1054
MariaDB limitations	1056
File size limits	1056
InnoDB reserved word	1057
Microsoft SQL Server on Amazon RDS	1058
Common management tasks	1059
Limitations	1060
DB instance class support	1062
Security	1064
Compliance programs	1065
HIPAA	1065
SSL support	1066
Version support	1066
Version management	1067
Database engine patches and versions	1067

Deprecation schedule	1067
Feature support	1068
SQL Server 2019 features	1068
SQL Server 2017 features	1069
SQL Server 2016 features	1069
SQL Server 2014 features	1069
SQL Server 2012 end of support on Amazon RDS	1070
SQL Server 2008 R2 end of support on Amazon RDS	1070
CDC support	1070
Features not supported and features with limited support	1071
Multi-AZ deployments	1071
Using TDE	1072
Functions and stored procedures	1072
Local time zone	1074
Supported time zones	1075
Licensing SQL Server on Amazon RDS	1083
Restoring license-terminated DB instances	1083
SQL Server Developer Edition	1083
Connecting to a DB instance running SQL Server	1084
Before you connect	1084
Finding the DB instance endpoint and port number	1084
Connecting to your DB instance with SSMS	1085
Connecting to your DB instance with SQL Workbench/J	1087
Security group considerations	1089
Troubleshooting	1089
Updating applications for new SSL/TLS certificates	1091
Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL	1091
Determining whether a client requires certificate verification in order to connect	1092
Updating your application trust store	1093
Upgrading the SQL Server DB engine	1094
Overview	1095
Major version upgrades	1095
Multi-AZ and in-memory optimization considerations	1096
Option group considerations	1097
Parameter group considerations	1097
Testing an upgrade	1097
Upgrading a SQL server DB instance	1098
Upgrading deprecated DB instances before support ends	1098
Importing and exporting SQL Server databases	1099
Limitations and recommendations	1100
Setting up	1101
Using native backup and restore	1105
Compressing backup files	1115
Troubleshooting	1115
Importing and exporting SQL Server data using other methods	1117
Working with SQL Server read replicas	1126
Configuring read replicas for SQL Server	1126
Read replica limitations with SQL Server	1126
Option considerations	1127
Troubleshooting a SQL Server read replica problem	1128
Multi-AZ for RDS for SQL Server	1129
Adding Multi-AZ to a SQL Server DB instance	1130
Removing Multi-AZ from a SQL Server DB instance	1130
Limitations, notes, and recommendations	1130
Determining the location of the secondary	1132
Migrating to Always On AGs	1133

Additional features for SQL Server	1134
Using SSL with a SQL Server DB instance	1135
Configuring security protocols and ciphers	1138
Using Windows Authentication with a SQL Server DB instance	1143
Amazon S3 integration	1153
Using Database Mail	1167
Instance store support for tempdb	1178
Using extended events	1180
Access to transaction log backups	1183
Options for SQL Server	1203
Listing the available options for SQL Server versions and editions	1204
Linked Servers with Oracle OLEDB	1206
Native backup and restore	1214
Transparent Data Encryption	1217
SQL Server Audit	1225
SQL Server Analysis Services	1232
SQL Server Integration Services	1251
SQL Server Reporting Services	1266
Microsoft Distributed Transaction Coordinator	1279
Common DBA tasks for SQL Server	1291
Accessing the tempdb database	1292
Analyzing database workload with Database Engine Tuning Advisor	1294
Collations and character sets	1296
Creating a database user	1299
Determining a recovery model	1300
Determining the last failover time	1300
Disabling fast inserts	1301
Dropping a SQL Server database	1301
Renaming a Multi-AZ database	1301
Resetting the db_owner role password	1302
Restoring license-terminated DB instances	1302
Transitioning a database from OFFLINE to ONLINE	1303
Using CDC	1303
Using SQL Server Agent	1305
Working with SQL Server logs	1308
Working with trace and dump files	1309
MySQL on Amazon RDS	1310
MySQL feature support	1312
Supported storage engines	1312
Using memcached and other options	1312
InnoDB cache warming	1313
Features not supported	1313
MySQL versions	1315
Supported MySQL versions	1315
MySQL release calendar	1316
Deprecated MySQL versions	1317
Connecting to a DB instance running MySQL	1318
Finding the connection information	1319
Connecting from the MySQL command-line client (unencrypted)	1321
Connecting from MySQL Workbench	1322
Connecting with the AWS JDBC Driver for MySQL	1323
Troubleshooting	1324
Securing MySQL connections	1325
MySQL security	1325
Password Validation Plugin	1326
Encrypting with SSL/TLS	1327
Using new SSL/TLS certificates	1330

Using Kerberos authentication for MySQL	1333
Upgrading the MySQL DB engine	1343
Overview	1343
Major version upgrades	1344
Testing an upgrade	1348
Upgrading a MySQL DB instance	1348
Automatic minor version upgrades	1348
Upgrading with reduced downtime	1350
Upgrading a MySQL DB snapshot	1353
Importing data into a MySQL DB instance	1355
Overview	1355
Importing data considerations	1357
Restoring a backup into a MySQL DB instance	1361
Importing data from an external database	1369
Importing data to a DB instance with reduced downtime	1371
Importing data from any source	1384
Working with MySQL replication	1389
Working with MySQL read replicas	1389
Using GTID-based replication	1401
Configuring GTID-based replication with an external source instance	1405
Configuring binary log file position replication with an external source instance	1408
Exporting data from a MySQL DB instance	1412
Prepare an external MySQL database	1412
Prepare the source MySQL DB instance	1413
Copy the database	1414
Complete the export	1414
Options for MySQL	1416
MariaDB Audit Plugin	1417
memcached	1422
Parameters for MySQL	1426
Common DBA tasks for MySQL	1428
Ending a session or query	1428
Skipping the current replication error	1428
Working with InnoDB tablespaces to improve crash recovery times	1429
Managing the global status history	1431
Local time zone	1433
Known issues and limitations	1435
InnoDB reserved word	1435
Storage-full behavior	1435
Inconsistent InnoDB buffer pool size	1436
Index merge optimization returns incorrect results	1436
Log file size	1437
MySQL parameter exceptions for Amazon RDS DB instances	1437
MySQL file size limits in Amazon RDS	1437
MySQL Keyring Plugin not supported	1438
MySQL on Amazon RDS SQL reference	1439
Overview	1439
SQL reference conventions	1440
mysql.rds_set_master_auto_position	1440
mysql.rds_set_external_master	1441
mysql.rds_set_external_master_with_delay	1443
mysql.rds_set_external_master_with_auto_position	1446
mysql.rds_reset_external_master	1448
mysql.rds_import_binlog_ssl_material	1449
mysql.rds_remove_binlog_ssl_material	1451
mysql.rds_set_source_delay	1451
mysql.rds_start_replication	1452

mysql.rds_start_replication_until	1452
mysql.rds_start_replication_until_gtid	1453
mysql.rds_stop_replication	1454
mysql.rds_skip_transaction_with_gtid	1455
mysql.rds_skip_repl_error	1455
mysql.rds_next_master_log	1456
mysql.rds_innodb_buffer_pool_dump_now	1458
mysql.rds_innodb_buffer_pool_load_now	1458
mysql.rds_innodb_buffer_pool_load_abort	1459
mysql.rds_set_configuration	1459
mysql.rds_show_configuration	1460
mysql.rds_kill	1461
mysql.rds_kill_query	1461

What is Amazon Relational Database Service (Amazon RDS)?

Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks.

Note

This guide covers Amazon RDS database engines other than Amazon Aurora. For information about using Amazon Aurora, see the [Amazon Aurora User Guide](#).

If you are new to AWS products and services, begin learning more with the following resources:

- For an overview of all AWS products, see [What is cloud computing?](#)
- Amazon Web Services provides a number of database services. For guidance on which service is best for your environment, see [Running databases on AWS](#).

Overview of Amazon RDS

Why do you want to run a relational database in the AWS Cloud? Because AWS takes over many of the difficult and tedious management tasks of a relational database.

Topics

- [Amazon EC2 and on-premises databases \(p. 1\)](#)
- [Amazon RDS and Amazon EC2 \(p. 2\)](#)
- [Amazon RDS Custom for Oracle and Microsoft SQL Server \(p. 3\)](#)
- [Amazon RDS on AWS Outposts \(p. 3\)](#)

Amazon EC2 and on-premises databases

Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. Amazon EC2 eliminates your need to invest in hardware up front, so you can develop and deploy applications faster.

When you buy an on-premises server, you get CPU, memory, storage, and IOPS, all bundled together. With Amazon EC2, these are split apart so that you can scale them independently. If you need more CPU, less IOPS, or more storage, you can easily allocate them.

For a relational database in an on-premises server, you assume full responsibility for the server, operating system, and software. For a database on an Amazon EC2 instance, AWS manages the layers below the operating system. In this way, Amazon EC2 eliminates some of the burden of managing an on-premises database server.

In the following table, you can find a comparison of the management models for on-premises databases and Amazon EC2.

Feature	On-premises management	Amazon EC2 management
Application optimization	Customer	Customer
Scaling	Customer	Customer
High availability	Customer	Customer
Database backups	Customer	Customer
Database software patching	Customer	Customer
Database software install	Customer	Customer
Operating system (OS) patching	Customer	Customer
OS installation	Customer	Customer
Server maintenance	Customer	AWS
Hardware lifecycle	Customer	AWS
Power, network, and cooling	Customer	AWS

Amazon EC2 isn't a fully managed service. Thus, when you run a database on Amazon EC2, you're more prone to user errors. For example, when you update the operating system or database software manually, you might accidentally cause application downtime. You might spend hours checking every change to identify and fix an issue.

Amazon RDS and Amazon EC2

Amazon RDS is a managed database service. It's responsible for most management tasks. By eliminating tedious manual tasks, Amazon RDS frees you to focus on your application and your users. We recommend Amazon RDS over Amazon EC2 as your default choice for most database deployments.

In the following table, you can find a comparison of the management models in Amazon EC2 and Amazon RDS.

Feature	Amazon EC2 management	Amazon RDS management
Application optimization	Customer	Customer
Scaling	Customer	AWS
High availability	Customer	AWS
Database backups	Customer	AWS
Database software patching	Customer	AWS
Database software install	Customer	AWS
OS patching	Customer	AWS
OS installation	Customer	AWS
Server maintenance	AWS	AWS
Hardware lifecycle	AWS	AWS

Feature	Amazon EC2 management	Amazon RDS management
Power, network, and cooling	AWS	AWS

Amazon RDS provides the following specific advantages over database deployments that aren't fully managed:

- You can use the database products you are already familiar with: MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL.
- Amazon RDS manages backups, software patching, automatic failure detection, and recovery.
- You can turn on automated backups, or manually create your own backup snapshots. You can use these backups to restore a database. The Amazon RDS restore process works reliably and efficiently.
- You can get high availability with a primary instance and a synchronous secondary instance that you can fail over to when problems occur. You can also use read replicas to increase read scaling.
- In addition to the security in your database package, you can help control who can access your RDS databases. To do so, you can use AWS Identity and Access Management (IAM) to define users and permissions. You can also help protect your databases by putting them in a virtual private cloud (VPC).

Amazon RDS Custom for Oracle and Microsoft SQL Server

Amazon RDS Custom is an RDS management type that gives you full access to your database and operating system.

You can use the control capabilities of RDS Custom to access and customize the database environment and operating system for legacy and packaged business applications. Meanwhile, Amazon RDS automates database administration tasks and operations.

In this deployment model, you can install applications and change configuration settings to suit your applications. At the same time, you can offload database administration tasks such as provisioning, scaling, upgrading, and backup to AWS. You can take advantage of the database management benefits of Amazon RDS, with more control and flexibility.

For Oracle Database and Microsoft SQL Server, RDS Custom combines the automation of Amazon RDS with the flexibility of Amazon EC2. For more information on RDS Custom, see [Working with Amazon RDS Custom \(p. 755\)](#).

With the shared responsibility model of RDS Custom, you get more control than in Amazon RDS, but also more responsibility. For more information, see [Shared responsibility model \(p. 756\)](#).

Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts extends RDS for SQL Server, RDS for MySQL, and RDS for PostgreSQL databases to AWS Outposts environments. AWS Outposts uses the same hardware as in public AWS Regions to bring AWS services, infrastructure, and operation models on-premises. With RDS on Outposts, you can provision managed DB instances close to the business applications that must run on-premises. For more information, see [Working with Amazon RDS on AWS Outposts \(p. 902\)](#).

DB instances

A *DB instance* is an isolated database environment in the AWS Cloud. The basic building block of Amazon RDS is the DB instance.

Your DB instance can contain one or more user-created databases. You can access your DB instance by using the same tools and applications that you use with a standalone database instance. You can create and modify a DB instance by using the AWS Command Line Interface (AWS CLI), the Amazon RDS API, or the AWS Management Console.

DB engines

A *DB engine* is the specific relational database software that runs on your DB instance. Amazon RDS currently supports the following engines:

- MariaDB
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL

Each DB engine has its own supported features, and each version of a DB engine can include specific features. Support for Amazon RDS features varies across AWS Regions and specific versions of each DB engine. To check feature support in different engine versions and Regions, see [Supported features in Amazon RDS by AWS Region and DB engine \(p. 77\)](#).

Additionally, each DB engine has a set of parameters in a DB parameter group that control the behavior of the databases that it manages.

DB instance classes

A *DB instance class* determines the computation and memory capacity of a DB instance. A DB instance class consists of both the DB instance type and the size. Each instance type offers different compute, memory, and storage capabilities. For example, db.m6g is a general-purpose DB instance type powered by AWS Graviton2 processors. Within the db.m6g instance type, db.m6g.2xlarge is a DB instance class.

You can select the DB instance that best meets your needs. If your needs change over time, you can change DB instances. For information, see [DB instance classes \(p. 10\)](#).

Note

For pricing information on DB instance classes, see the Pricing section of the [Amazon RDS product page](#).

DB instance storage

Amazon EBS provides durable, block-level storage volumes that you can attach to a running instance. DB instance storage comes in the following types:

- General Purpose (SSD)
- Provisioned IOPS (PIOPS)
- Magnetic

The storage types differ in performance characteristics and price. You can tailor your storage performance and cost to the needs of your database.

Each DB instance has minimum and maximum storage requirements depending on the storage type and the database engine it supports. It's important to have sufficient storage so that your databases have room to grow. Also, sufficient storage makes sure that features for the DB engine have room to write content or log entries. For more information, see [Amazon RDS DB instance storage \(p. 64\)](#).

Amazon Virtual Private Cloud (Amazon VPC)

You can run a DB instance on a virtual private cloud (VPC) using the Amazon Virtual Private Cloud (Amazon VPC) service. When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. The basic functionality of Amazon RDS is the same whether it's running in a VPC or not. Amazon RDS manages backups, software patching, automatic failure detection, and recovery. There's no additional cost to run your DB instance in a VPC. For more information on using Amazon VPC with RDS, see [Amazon VPC VPCs and Amazon RDS \(p. 2103\)](#).

Amazon RDS uses Network Time Protocol (NTP) to synchronize the time on DB Instances.

AWS Regions and Availability Zones

Amazon cloud computing resources are housed in highly available data center facilities in different areas of the world (for example, North America, Europe, or Asia). Each data center location is called an AWS Region.

Each AWS Region contains multiple distinct locations called Availability Zones, or AZs. Each Availability Zone is engineered to be isolated from failures in other Availability Zones. Each is engineered to provide inexpensive, low-latency network connectivity to other Availability Zones in the same AWS Region. By launching instances in separate Availability Zones, you can protect your applications from the failure of a single location. For more information, see [Regions, Availability Zones, and Local Zones \(p. 72\)](#).

You can run your DB instance in several Availability Zones, an option called a Multi-AZ deployment. When you choose this option, Amazon automatically provisions and maintains one or more secondary standby DB instances in a different Availability Zone. Your primary DB instance is replicated across Availability Zones to each secondary DB instance. This approach helps provide data redundancy and failover support, eliminate I/O freezes, and minimize latency spikes during system backups. In a Multi-AZ DB clusters deployment, the secondary DB instances can also serve read traffic. For more information, see [Multi-AZ deployments for high availability \(p. 121\)](#).

Security

A *security group* controls the access to a DB instance. It does so by allowing access to IP address ranges or Amazon EC2 instances that you specify.

For more information about security groups, see [Security in Amazon RDS \(p. 1997\)](#).

Monitoring an Amazon RDS DB instance

There are several ways that you can track the performance and health of a DB instance. You can use the Amazon CloudWatch service to monitor the performance and health of a DB instance. CloudWatch performance charts are shown in the Amazon RDS console. You can also subscribe to Amazon RDS events to be notified about changes to a DB instance, DB snapshot, or DB parameter group. For more information, see [Monitoring metrics in an Amazon RDS instance \(p. 510\)](#).

How to work with Amazon RDS

There are several ways that you can interact with Amazon RDS.

AWS Management Console

The AWS Management Console is a simple web-based user interface. You can manage your DB instances from the console with no programming required. To access the Amazon RDS console, sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

Command line interface

You can use the AWS Command Line Interface (AWS CLI) to access the Amazon RDS API interactively. To install the AWS CLI, see [Installing the AWS Command Line Interface](#). To begin using the AWS CLI for RDS, see [AWS Command Line Interface reference for Amazon RDS](#).

Programming with Amazon RDS

If you are a developer, you can access the Amazon RDS programmatically. For more information, see [Amazon RDS API reference \(p. 2155\)](#).

For application development, we recommend that you use one of the AWS Software Development Kits (SDKs). The AWS SDKs handle low-level details such as authentication, retry logic, and error handling, so that you can focus on your application logic. AWS SDKs are available for a wide variety of languages. For more information, see [Tools for Amazon web services](#).

AWS also provides libraries, sample code, tutorials, and other resources to help you get started more easily. For more information, see [Sample code & libraries](#).

How you are charged for Amazon RDS

When you use Amazon RDS, you can choose to use on-demand DB instances or reserved DB instances. For more information, see [DB instance billing for Amazon RDS \(p. 138\)](#).

For Amazon RDS pricing information, see the [Amazon RDS product page](#).

What's next?

The preceding section introduced you to the basic infrastructure components that RDS offers. What should you do next?

Getting started

Create a DB instance using instructions in [Getting started with Amazon RDS \(p. 153\)](#).

Topics specific to database engines

You can review information specific to a particular DB engine in the following sections:

- [Amazon RDS for MariaDB \(p. 974\)](#)
- [Amazon RDS for Microsoft SQL Server \(p. 1058\)](#)
- [Amazon RDS for MySQL \(p. 1310\)](#)
- [Amazon RDS for Oracle \(p. 1466\)](#)
- [Amazon RDS for PostgreSQL \(p. 1798\)](#)

Amazon RDS DB instances

A *DB instance* is an isolated database environment running in the cloud. It is the basic building block of Amazon RDS. A DB instance can contain multiple user-created databases, and can be accessed using the same client tools and applications you might use to access a standalone database instance. DB instances are simple to create and modify with the AWS command line tools, Amazon RDS API operations, or the AWS Management Console.

Note

Amazon RDS supports access to databases using any standard SQL client application. Amazon RDS does not allow direct host access.

You can have up to 40 Amazon RDS DB instances, with the following limitations:

- 10 for each SQL Server edition (Enterprise, Standard, Web, and Express) under the "license-included" model
- 10 for Oracle under the "license-included" model
- 40 for MySQL, MariaDB, or PostgreSQL
- 40 for Oracle under the "bring-your-own-license" (BYOL) licensing model

Note

If your application requires more DB instances, you can request additional DB instances by using [this form](#).

Each DB instance has a DB instance identifier. This customer-supplied name uniquely identifies the DB instance when interacting with the Amazon RDS API and AWS CLI commands. The DB instance identifier must be unique for that customer in an AWS Region.

The identifier is used as part of the DNS hostname allocated to your instance by RDS. For example, if you specify db1 as the DB instance identifier, then RDS will automatically allocate a DNS endpoint for your instance, such as db1.123456789012.us-east-1.rds.amazonaws.com, where 123456789012 is the fixed identifier for a specific region for your account.

Each DB instance supports a database engine. Amazon RDS currently supports MySQL, MariaDB, PostgreSQL, Oracle, Microsoft SQL Server, and Amazon Aurora database engines.

When creating a DB instance, some database engines require that a database name be specified. A DB instance can host multiple databases, or a single Oracle database with multiple schemas. The database name value depends on the database engine:

- For the MySQL and MariaDB database engines, the database name is the name of a database hosted in your DB instance. Databases hosted by the same DB instance must have a unique name within that instance.
- For the Oracle database engine, database name is used to set the value of ORACLE_SID, which must be supplied when connecting to the Oracle RDS instance.
- For the Microsoft SQL Server database engine, database name is not a supported parameter.
- For the PostgreSQL database engine, the database name is the name of a database hosted in your DB instance. A database name is not required when creating a DB instance. Databases hosted by the same DB instance must have a unique name within that instance.

Amazon RDS creates a master user account for your DB instance as part of the creation process. This master user has permissions to create databases and to perform create, delete, select, update, and insert operations on tables the master user creates. You must set the master user password when you create a DB instance, but you can change it at any time using the AWS CLI, Amazon RDS API operations, or the

AWS Management Console. You can also change the master user password and manage users using standard SQL commands.

Note

This guide covers non-Aurora Amazon RDS database engines. For information about using Amazon Aurora, see the [Amazon Aurora User Guide](#).

DB instance classes

The DB instance class determines the computation and memory capacity of an Amazon RDS DB instance. The DB instance class that you need depends on your processing power and memory requirements.

A DB instance class consists of both the DB instance type and the size. For example, db.m6g is a general-purpose DB instance type powered by AWS Graviton2 processors. Within the db.m6g instance type, db.m6g.2xlarge is a DB instance class.

For more information about instance class pricing, see [Amazon RDS pricing](#).

Topics

- [DB instance class types \(p. 10\)](#)
- [Supported DB engines for DB instance classes \(p. 12\)](#)
- [Determining DB instance class support in AWS Regions \(p. 39\)](#)
- [Changing your DB instance class \(p. 42\)](#)
- [Configuring the processor for a DB instance class \(p. 42\)](#)
- [Hardware specifications for DB instance classes \(p. 55\)](#)

DB instance class types

Amazon RDS supports three types of instance classes: general purpose, memory optimized, and burstable performance. For more information about Amazon EC2 instance types, see [Instance types](#) in the Amazon EC2 documentation.

The following are the general-purpose DB instance types available:

- **db.m6g** – General-purpose instance classes powered by AWS Graviton2 processors. These deliver balanced compute, memory, and networking for a broad range of general-purpose workloads.

You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.

- **db.m6gd** – General-purpose instance classes powered by AWS Graviton2 processors. These deliver balanced compute, memory, and networking for a broad range of general-purpose workloads. These have local NVMe-based SSD block-level storage for applications that need high-speed, low latency local storage.

These DB instance classes are only supported for Multi-AZ DB clusters. For more information about Multi-AZ DB clusters, see [Multi-AZ DB cluster deployments \(p. 127\)](#).

- **db.m6i** – General-purpose instance classes that are well suited for a broad range of general-purpose workloads.
- **db.m5d** – General-purpose instance classes that are optimized for low latency, very high random I/O performance, and high sequential read throughput.

For the RDS for MySQL and RDS for PostgreSQL DB engines, these DB instance classes are only supported for Multi-AZ DB clusters. For more information about Multi-AZ DB clusters, see [Multi-AZ DB cluster deployments \(p. 127\)](#).

- **db.m5** – General-purpose instance classes that provide a balance of compute, memory, and network resources, and are a good choice for many applications. The db.m5 instance classes provide more computing capacity than the previous db.m4 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.
- **db.m4** – General-purpose instance classes that provide more computing capacity than the previous db.m3 instance classes.

- **db.m3** – General-purpose instance classes that provide more computing capacity than the previous db.m1 instance classes.

Amazon RDS has started the end-of-life process for db.m3 DB instance classes using the following schedule, which includes upgrade recommendations. For all RDS DB instances that use db.m3 DB instance classes, we recommend that you upgrade to a db.m5 DB instance class as soon as possible.

Action or recommendation	Dates
We recommend that you manually upgrade db.m3 DB instance classes to db.m5 DB instance classes for your RDS DB instances.	Now–February 1, 2023
You can no longer create RDS DB instances that use db.m3 DB instance classes.	Now
Amazon RDS starts automatic upgrades of RDS DB instances that use db.m3 DB instance classes to equivalent db.m5 DB instance classes.	February 1, 2023

The following are the memory optimized DB instance types available:

- **db.x2g** – Instance classes optimized for memory-intensive applications and powered by AWS Graviton2 processors. These offer low cost per GiB of memory.

You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.
- **db.z1d** – Instance classes optimized for memory-intensive applications. These offer both high compute capacity and a high memory footprint. High frequency z1d instances deliver a sustained all core frequency of up to 4.0 GHz.
- **db.x1e** – Instance classes optimized for memory-intensive applications. These offer one of the lowest price per gibibyte (GiB) of RAM among the DB instance classes and up to 3,904 GiB of DRAM-based instance memory.
- **db.x1** – Instance classes optimized for memory-intensive applications. These offer one of the lowest price per GiB of RAM among the DB instance classes and up to 1,952 GiB of DRAM-based instance memory.
- **db.r6g** – Instance classes powered by AWS Graviton2 processors. These are ideal for running memory-intensive workloads in open-source databases such as MySQL and PostgreSQL.

You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.

- **db.r6gd** – Instance classes powered by AWS Graviton2 processors. These are ideal for running memory-intensive workloads in open-source databases such as MySQL and PostgreSQL. These have local NVMe-based SSD block-level storage for applications that need high-speed, low latency local storage.

These DB instance classes are only supported for Multi-AZ DB clusters. For more information about Multi-AZ DB clusters, see [Multi-AZ DB cluster deployments \(p. 127\)](#).

- **db.r6i** – Instance classes that are ideal for running memory-intensive workloads.
- **db.r5b** – Instance classes that are memory optimized for throughput-intensive applications. Powered by the AWS Nitro System, db.r5b instances deliver up to 60 Gbps bandwidth and 260,000 IOPS of EBS performance. This is the fastest block storage performance on EC2.
- **db.r5d** – Instance classes that are optimized for low latency, very high random I/O performance, and high sequential read throughput.

For the RDS for MySQL and RDS for PostgreSQL DB engines, these DB instance classes are only supported for Multi-AZ DB clusters. For more information about Multi-AZ DB clusters, see [Multi-AZ DB cluster deployments \(p. 127\)](#).

- **db.r5** – Instance classes optimized for memory-intensive applications. These offer improved networking and Amazon Elastic Block Store (Amazon EBS) performance. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.
- **db.r3** – Instance classes that provide memory optimization.

Amazon RDS has started the end-of-life process for db.r3 DB instance classes using the following schedule, which includes upgrade recommendations. For all RDS DB instances that use db.r3 DB instance classes, we recommend that you upgrade to a db.r5 DB instance class as soon as possible.

Action or recommendation	Dates
We recommend that you manually upgrade db.r3 DB instance classes to db.r5 DB instance classes for your RDS DB instances.	Now–February 1, 2023
You can no longer create RDS DB instances that use db.r3 DB instance classes.	Now
Amazon RDS starts automatic upgrades of RDS DB instances that use db.r3 DB instance classes to equivalent db.r5 DB instance classes.	February 1, 2023

The following are the burstable-performance DB instance types available:

- **db.t4g** – General-purpose instance classes powered by Arm-based AWS Graviton2 processors. These deliver better price performance than previous burstable-performance DB instance classes for a broad set of burstable general-purpose workloads. Amazon RDS T4g instances are configured for Unlimited mode. This means that they can burst beyond the baseline over a 24-hour window for an additional charge.

You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.

- **db.t3** – Instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. T3 instances are configured for Unlimited mode. These instance classes provide more computing capacity than the previous db.t2 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.
- **db.t2** – Instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. T2 instances can be configured for Unlimited mode. We recommend using these instance classes only for development and test servers, or other nonproduction servers.

Note

The DB instance classes that use the AWS Nitro System (db.m5, db.r5, db.t3) are throttled on combined read plus write workload.

For DB instance class hardware specifications, see [Hardware specifications for DB instance classes \(p. 55\)](#).

Supported DB engines for DB instance classes

The following are DB engine-specific considerations for DB instance classes:

Microsoft SQL Server

DB instance class support varies according to the version and edition of SQL Server. For instance class support by version and edition, see [DB instance class support for Microsoft SQL Server \(p. 1062\)](#).

Oracle

DB instance class support varies according to the Oracle Database version and edition. RDS for Oracle supports additional memory-optimized instance classes. These classes have names of the form db.r5.*instance_size*.tpc*threads_per_core*.mem*ratio*. For the vCPU count and memory allocation for each optimized class, see [Supported RDS for Oracle instance classes \(p. 1477\)](#).

In the following table, you can find details about supported Amazon RDS DB instance classes for each Amazon RDS DB engine.

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.m6g – general-purpose instance classes powered by AWS Graviton2 processors					
db.m6g.16xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions, PostgreSQL 12.7 and higher
db.m6g.12xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions, PostgreSQL 12.7 and higher
db.m6g.8xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions, PostgreSQL 12.7 and higher
db.m6g.4xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions, PostgreSQL

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
					12.7 and higher
db.m6g.2xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions, PostgreSQL 12.7 and higher
db.m6g.xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions, PostgreSQL 12.7 and higher
db.m6g.large	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions, PostgreSQL 12.7 and higher
db.m6gd – general-purpose instance classes powered by AWS Graviton2 processors					
db.m6gd.16xlarge	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters
db.m6gd.12xlarge	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters
db.m6gd.8xlarge	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters
db.m6gd.4xlarge	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.m6gd.2xlarge	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters
db.m6gd.xlarge	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters
db.m6gd.large	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters
db.m6i – general-purpose instance classes					
db.m6i.32xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Oracle Database 19c	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher
db.m6i.24xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Oracle Database 19c	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.m6i.16xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Oracle Database 19c	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher
db.m6i.12xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Oracle Database 19c	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher
db.m6i.8xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Oracle Database 19c	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.m6i.4xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Oracle Database 19c	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher
db.m6i.2xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Oracle Database 19c	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher
db.m6i.xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Oracle Database 19c	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.m6i.large	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Oracle Database 19c	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher
db.m5d – general-purpose instance classes					
db.m5d.24xlarge	No	Yes	MySQL 8.0.28 & higher Multi-AZ DB clusters	Yes	PostgreSQL 13.4 Multi-AZ DB clusters
db.m5d.16xlarge	No	Yes	MySQL 8.0.28 & higher Multi-AZ DB clusters	Yes	PostgreSQL 13.4 Multi-AZ DB clusters
db.m5d.12xlarge	No	Yes	MySQL 8.0.28 & higher Multi-AZ DB clusters	Yes	PostgreSQL 13.4 Multi-AZ DB clusters
db.m5d.8xlarge	No	Yes	MySQL 8.0.28 & higher Multi-AZ DB clusters	Yes	PostgreSQL 13.4 Multi-AZ DB clusters
db.m5d.4xlarge	No	Yes	MySQL 8.0.28 & higher Multi-AZ DB clusters	Yes	PostgreSQL 13.4 Multi-AZ DB clusters
db.m5d.2xlarge	No	Yes	MySQL 8.0.28 & higher Multi-AZ DB clusters	Yes	PostgreSQL 13.4 Multi-AZ DB clusters
db.m5d.xlarge	No	Yes	MySQL 8.0.28 & higher Multi-AZ DB clusters	Yes	PostgreSQL 13.4 Multi-AZ DB clusters

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.m5d.large	No	Yes	MySQL 8.0.28 & higher Multi-AZ DB clusters	Yes	PostgreSQL 13.4 Multi-AZ DB clusters
db.m5 – general-purpose instance classes					
db.m5.24xlarge	Yes	Yes	Yes	Yes	All PostgreSQL 14, 13, 12, and 11 versions; 10.17 and higher; 9.6.22 and higher
db.m5.16xlarge	Yes	Yes	Yes	Yes	All PostgreSQL 14, 13, 12, and 11 versions; 10.17 and higher; 9.6.22 and higher
db.m5.12xlarge	Yes	Yes	Yes	Yes	All PostgreSQL 14, 13, 12, and 11 versions; 10.17 and higher; 9.6.22 and higher
db.m5.8xlarge	Yes	Yes	Yes	Yes	All PostgreSQL 14, 13, 12, and 11 versions; 10.17 and higher; 9.6.22 and higher
db.m5.4xlarge	Yes	Yes	Yes	Yes	All PostgreSQL 14, 13, 12, and 11 versions; 10.17 and higher; 9.6.22 and higher

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.m5.2xlarge	Yes	Yes	Yes	Yes	All PostgreSQL 14, 13, 12, and 11 versions; 10.17 and higher; 9.6.22 and higher
db.m5.xlarge	Yes	Yes	Yes	Yes	All PostgreSQL 14, 13, 12, and 11 versions; 10.17 and higher; 9.6.22 and higher
db.m5.large	Yes	Yes	Yes	Yes	All PostgreSQL 14, 13, 12, and 11 versions; 10.17 and higher; 9.6.22 and higher
db.m4 – general-purpose instance classes					
db.m4.16xlarge	Yes	Yes	MySQL 8.0, 5.7	Yes	Lower than PostgreSQL 13
db.m4.10xlarge	Yes	Yes	Yes	Yes	Lower than PostgreSQL 13
db.m4.4xlarge	Yes	Yes	Yes	Yes	Lower than PostgreSQL 13
db.m4.2xlarge	Yes	Yes	Yes	Yes	Lower than PostgreSQL 13
db.m4.xlarge	Yes	Yes	Yes	Yes	Lower than PostgreSQL 13
db.m4.large	Yes	Yes	Yes	Yes	Lower than PostgreSQL 13
db.m3 – general-purpose instance classes					

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.m3.2xlarge	No	Yes	Yes	Deprecated	Lower than PostgreSQL 13
db.m3.xlarge	No	Yes	Yes	Deprecated	Lower than PostgreSQL 13
db.m3.large	No	Yes	Yes	Deprecated	Lower than PostgreSQL 13
db.m3.medium	No	Yes	Yes	Deprecated	Lower than PostgreSQL 13
db.x2g – memory-optimized instance classes powered by AWS Graviton2 processors					
db.x2g.16xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.25 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher
db.x2g.12xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.25 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher
db.x2g.8xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.25 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.x2g.4xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.25 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher
db.x2g.2xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.25 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher
db.x2g.xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.25 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher
db.x2g.large	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.25 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher
db.z1d – memory-optimized instance classes					
db.z1d.12xlarge	No	Yes	No	Yes	No
db.z1d.6xlarge	No	Yes	No	Yes	No
db.z1d.3xlarge	No	Yes	No	Yes	No
db.z1d.2xlarge	No	Yes	No	Yes	No
db.z1d.xlarge	No	Yes	No	Yes	No
db.z1d.large	No	Yes	No	Yes	No
db.x1e – memory-optimized instance classes					

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.x1e.32xlarge	No	Yes	No	Yes	No
db.x1e.16xlarge	No	Yes	No	Yes	No
db.x1e.8xlarge	No	Yes	No	Yes	No
db.x1e.4xlarge	No	Yes	No	Yes	No
db.x1e.2xlarge	No	Yes	No	Yes	No
db.x1e.xlarge	No	Yes	No	Yes	No
db.x1 – memory-optimized instance classes					
db.x1.32xlarge	No	Yes	No	Yes	No
db.x1.16xlarge	No	Yes	No	Yes	No
db.r6g – memory-optimized instance classes powered by AWS Graviton2 processors					
db.r6g.16xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher
db.r6g.12xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher
db.r6g.8xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.r6g.4xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher
db.r6g.2xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher
db.r6g.xlarge	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher
db.r6g.large	All MariaDB 10.6 versions, all MariaDB 10.5 versions, and all MariaDB 10.4 versions	No	MySQL 8.0.23 & higher	No	All PostgreSQL 14 versions, all PostgreSQL 13 versions; PostgreSQL 12.7 and higher
db.r6gd – memory-optimized instance classes powered by AWS Graviton2 processors					
db.r6gd.16xlarge	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters
db.r6gd.12xlarge	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.r6gd.8xlarge	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters
db.r6gd.4xlarge	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters
db.r6gd.2xlarge	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters
db.r6gd.xlarge	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters
db.r6gd.large	No	No	MySQL 8.0.28 & higher Multi-AZ DB clusters	No	PostgreSQL 13.4 Multi-AZ DB clusters
db.r6i – memory-optimized instance classes					
db.r6i.32xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Yes	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.r6i.24xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Yes	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher
db.r6i.16xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Yes	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher
db.r6i.12xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Yes	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.r6i.8xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Yes	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher
db.r6i.4xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Yes	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher
db.r6i.2xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Yes	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.r6i.xlarge	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Yes	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher
db.r6i.large	MariaDB version 10.6.7 & higher 10.6 versions, MariaDB version 10.5.15 & higher 10.5 versions, and MariaDB version 10.4.24 & higher 10.4 versions	Yes	MySQL version 8.0.28 & higher 8.0 versions	Yes	All PostgreSQL 14 versions; PostgreSQL 13.4, 12.8, 11.13 and higher
db.r5d – memory-optimized instance classes					
db.r5d.24xlarge	No	Yes	MySQL 8.0.28 & higher Multi-AZ DB clusters	Yes	PostgreSQL 13.4 Multi-AZ DB clusters
db.r5d.16xlarge	No	Yes	MySQL 8.0.28 & higher Multi-AZ DB clusters	Yes	PostgreSQL 13.4 Multi-AZ DB clusters
db.r5d.12xlarge	No	Yes	MySQL 8.0.28 & higher Multi-AZ DB clusters	Yes	PostgreSQL 13.4 Multi-AZ DB clusters

Determining DB instance class support in AWS Regions

To determine the DB instance classes supported by each DB engine in a specific AWS Region, you can take one of several approaches. You can use the AWS Management Console, the [Amazon RDS Pricing](#) page, or the `describe-orderable-db-instance-options` command for the AWS Command Line Interface (AWS CLI).

Note

When you perform operations with the AWS CLI, it automatically shows the supported DB instance classes for a specific DB engine, DB engine version, and AWS Region. Examples of the operations that you can perform include creating and modifying a DB instance.

Contents

- [Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions \(p. 39\)](#)
- [Using the AWS CLI to determine DB instance class support in AWS Regions \(p. 40\)](#)
 - [Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region \(p. 40\)](#)
 - [Listing the DB engine versions that support a specific DB instance class in an AWS Region \(p. 41\)](#)

Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions

You can use the [Amazon RDS Pricing](#) page to determine the DB instance classes supported by each DB engine in a specific AWS Region.

To use the pricing page to determine the DB instance classes supported by each engine in a Region

1. Go to [Amazon RDS Pricing](#).
2. Choose a DB engine.
3. On the pricing page for the DB engine, choose **On-Demand DB Instances** or **Reserved DB Instances**.
4. To see the DB instance classes available in an AWS Region, choose the AWS Region in **Region**.

Other choices might be available for some DB engines, such as **Single-AZ Deployment** or **Multi-AZ Deployment**.

Using the AWS CLI to determine DB instance class support in AWS Regions

You can use the AWS CLI to determine which DB instance classes are supported for specific DB engines and DB engine versions in an AWS Region. The following table shows the valid DB engine values.

Engine names	Engine values in CLI commands	More information about versions
MariaDB	mariadb	MariaDB on Amazon RDS versions (p. 982)
Microsoft SQL Server	sqlserver-ee sqlserver-se sqlserver-ex sqlserver-web	Microsoft SQL Server versions on Amazon RDS (p. 1066)
MySQL	mysql	MySQL on Amazon RDS versions (p. 1315)
Oracle	oracle-ee oracle-se2 oracle-se	Amazon RDS for Oracle Release Notes
PostgreSQL	postgres	Available PostgreSQL database versions (p. 1805)

For information about AWS Region names, see [AWS Regions \(p. 73\)](#).

The following examples demonstrate how to determine DB instance class support in an AWS Region using the [describe-orderable-db-instance-options](#) AWS CLI command.

Note

To limit the output, these examples show results only for the General Purpose SSD (gp2) storage type. If necessary, you can change the storage type to General Purpose SSD (gp3), Provisioned IOPS (io1), or magnetic (standard) in the commands.

- [Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region \(p. 40\)](#)
- [Listing the DB engine versions that support a specific DB instance class in an AWS Region \(p. 41\)](#)

Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region

To list the DB instance classes that are supported by a specific DB engine version in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine engine --engine-version version \
--query "[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}|[? \
StorageType=='gp2']|[].{DBInstanceClass:DBInstanceClass}" \
--output text \
--region region
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine engine --engine-version version ^
--query "[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}|[? \
StorageType=='gp2']|[].{DBInstanceClass:DBInstanceClass}" ^
--output text ^
--region region
```

For example, the following command lists the supported DB instance classes for version 13.6 of the RDS for PostgreSQL DB engine in US East (N. Virginia).

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine postgres --engine-version 13.6 \
--query "[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}|[? \
StorageType=='gp2']|[].{DBInstanceClass:DBInstanceClass}" \
--output text \
--region us-east-1
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine postgres --engine-version 13.6 ^
--query "[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}|[? \
StorageType=='gp2']|[].{DBInstanceClass:DBInstanceClass}" ^
--output text ^
--region us-east-1
```

Listing the DB engine versions that support a specific DB instance class in an AWS Region

To list the DB engine versions that support a specific DB instance class in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine engine --db-instance-
class DB_instance_class \
--query "[].{EngineVersion:EngineVersion,StorageType:StorageType}|[? \
StorageType=='gp2']|[].{EngineVersion:EngineVersion}" \
--output text \
--region region
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine engine --db-instance-
class DB_instance_class ^
--query "[].{EngineVersion:EngineVersion,StorageType:StorageType}|[? \
StorageType=='gp2']|[].{EngineVersion:EngineVersion}" ^
--output text ^
--region region
```

For example, the following command lists the DB engine versions of the RDS for PostgreSQL DB engine that support the db.r5.large DB instance class in US East (N. Virginia).

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine postgres --db-instance-class db.r5.large \
    --query "[].{EngineVersion:EngineVersion,StorageType:StorageType}|[?StorageType=='gp2']|[].{EngineVersion:EngineVersion}" \
    --output text \
    --region us-east-1
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine postgres --db-instance-class db.r5.large ^
    --query "[].{EngineVersion:EngineVersion,StorageType:StorageType}|[?StorageType=='gp2']|[].{EngineVersion:EngineVersion}" ^
    --output text ^
    --region us-east-1
```

Changing your DB instance class

You can change the CPU and memory available to a DB instance by changing its DB instance class. To change the DB instance class, modify your DB instance by following the instructions in [Modifying an Amazon RDS DB instance \(p. 327\)](#).

Configuring the processor for a DB instance class

Amazon RDS DB instance classes support Intel Hyper-Threading Technology, which enables multiple threads to run concurrently on a single Intel Xeon CPU core. Each thread is represented as a virtual CPU (vCPU) on the DB instance. A DB instance has a default number of CPU cores, which varies according to DB instance class. For example, a db.m4.xlarge DB instance class has two CPU cores and two threads per core by default—four vCPUs in total.

Note

Each vCPU is a hyperthread of an Intel Xeon CPU core.

Topics

- [Overview of configuring the processor \(p. 42\)](#)
- [DB instance classes that support processor configuration \(p. 43\)](#)
- [Setting the CPU cores and threads per CPU core for a DB instance class \(p. 47\)](#)

Overview of configuring the processor

In most cases, you can find a DB instance class that has a combination of memory and number of vCPUs to suit your workloads. However, you can also specify the following processor features to optimize your DB instance for specific workloads or business needs:

- **Number of CPU cores** – You can customize the number of CPU cores for the DB instance. You might do this to potentially optimize the licensing costs of your software with a DB instance that has sufficient amounts of RAM for memory-intensive workloads but fewer CPU cores.
- **Threads per core** – You can disable Intel Hyper-Threading Technology by specifying a single thread per CPU core. You might do this for certain workloads, such as high-performance computing (HPC) workloads.

You can control the number of CPU cores and threads for each core separately. You can set one or both in a request. After a setting is associated with a DB instance, the setting persists until you change it.

The processor settings for a DB instance are associated with snapshots of the DB instance. When a snapshot is restored, its restored DB instance uses the processor feature settings used when the snapshot was taken.

If you modify the DB instance class for a DB instance with nondefault processor settings, either specify default processor settings or explicitly specify processor settings at modification. This requirement ensures that you are aware of the third-party licensing costs that might be incurred when you modify the DB instance.

There is no additional or reduced charge for specifying processor features on an Amazon RDS DB instance. You're charged the same as for DB instances that are launched with default CPU configurations.

DB instance classes that support processor configuration

You can configure the number of CPU cores and threads per core only when the following conditions are met:

- You're configuring an Oracle DB instance. For information about the DB instance classes supported by different Oracle database editions, see [RDS for Oracle instance classes \(p. 1477\)](#).
- Your instance is using the Bring Your Own License (BYOL) licensing option. For more information about Oracle licensing options, see [RDS for Oracle licensing options \(p. 1474\)](#).
- Your instance doesn't belong to one of the db.r5 or db.r5b instance classes that have predefined processor configurations. These instance classes have names in the form db.r5.*instance_size*.tpc*threads_per_core*.mem*ratio* or db.r5b.*instance_size*.tpc*threads_per_core*.mem*ratio*. For example, db.r5b.xlarge.tpc2.mem4x is preconfigured with 2 threads per core (tpc2) and 4x as much memory as the standard db.r5b.xlarge instance class. You can't configure the processor features of these optimized instance classes. For more information, see [Supported RDS for Oracle instance classes \(p. 1477\)](#).

In the following table, you can find the DB instance classes that support setting a number of CPU cores and CPU threads per core. You can also find the default value and the valid values for the number of CPU cores and CPU threads per core for each DB instance class.

DB instance class	Default vCPUs	Default CPU cores	Default threads per core	Valid number of CPU cores	Valid number of threads per core
db.m5.large	2	1	2	1	1, 2
db.m5.xlarge	4	2	2	2	1, 2

Note

You can use AWS CloudTrail to monitor and audit changes to the process configuration of Amazon RDS for Oracle DB instances. For more information about using CloudTrail, see [Monitoring Amazon RDS API calls in AWS CloudTrail \(p. 725\)](#).

Setting the CPU cores and threads per CPU core for a DB instance class

You can configure the number of CPU cores and threads per core for the DB instance class when you perform the following operations:

- [Creating an Amazon RDS DB instance \(p. 230\)](#)
- [Modifying an Amazon RDS DB instance \(p. 327\)](#)
- [Restoring from a DB snapshot \(p. 452\)](#)
- [Restoring a DB instance to a specified time \(p. 499\)](#)
- [Restoring a backup into a MySQL DB instance \(p. 1361\)](#)

Note

When you modify a DB instance to configure the number of CPU cores or threads per core, there is a brief DB instance outage.

You can set the CPU cores and the threads per CPU core for a DB instance class using the AWS Management Console, the AWS CLI, or the RDS API.

Console

When you are creating, modifying, or restoring a DB instance, you set the DB instance class in the AWS Management Console. The **Instance specifications** section shows options for the processor. The following image shows the processor features options.

Instance specifications

Estimate your monthly costs for the DB Instance using the [AWS Simple Monthly Calculator](#)

DB engine
Oracle Database Enterprise Edition

License model [Info](#)
bring-your-own-license

DB engine version [Info](#)
Oracle 12.1.0.2.v12

DB instance class [Info](#)
db.r4.xlarge — 4 vCPU, 30.5 GiB RAM

Multi-AZ deployment [Info](#)
 Create replica in different zone
Creates a replica in a different Availability Zone (AZ) to provide data redundancy, eliminate I/O freezes, and minimize latency spikes during system backups.
 No

Storage type [Info](#)
Provisioned IOPS (SSD)

Allocated storage
100 GiB
(Minimum: 100 GiB, Maximum: 16384 GiB)

Provisioned IOPS [Info](#)
1000

▼ Additional configuration

Processor features

Override default values
You can change the number of CPU cores and threads per core on the DB instance class.

Core count [Info](#)
2

Threads per core [Info](#)
2

Set the following options to the appropriate values for your DB instance class under **Processor features**:

- **Core count** – Set the number of CPU cores using this option. The value must be equal to or less than the maximum number of CPU cores for the DB instance class.
- **Threads per core** – Specify **2** to enable multiple threads per core, or specify **1** to disable multiple threads per core.

When you modify or restore a DB instance, you can also set the CPU cores and the threads per CPU core to the defaults for the instance class.

When you view the details for a DB instance in the console, you can view the processor information for its DB instance class on the **Configuration** tab. The following image shows a DB instance class with one CPU core and multiple threads per core enabled.

Instance and IOPS	
Instance Class	db.r4.large
Core count	1
Threads per core	2
vCPU enabled	2
Storage Type	Provisioned IOPS (SSD)
IOPS	1000
Storage	100 GiB

For Oracle DB instances, the processor information only appears for Bring Your Own License (BYOL) DB instances.

AWS CLI

You can set the processor features for a DB instance when you run one of the following AWS CLI commands:

- [create-db-instance](#)

- [modify-db-instance](#)
- [restore-db-instance-from-db-snapshot](#)
- [restore-db-instance-from-s3](#)
- [restore-db-instance-to-point-in-time](#)

To configure the processor of a DB instance class for a DB instance by using the AWS CLI, include the `--processor-features` option in the command. Specify the number of CPU cores with the `coreCount` feature name, and specify whether multiple threads per core are enabled with the `threadsPerCore` feature name.

The option has the following syntax.

```
--processor-features "Name=coreCount,Value=<value>" "Name=threadsPerCore,Value=<value>"
```

The following are examples that configure the processor:

Examples

- [Setting the number of CPU cores for a DB instance \(p. 51\)](#)
- [Setting the number of CPU cores and disabling multiple threads for a DB instance \(p. 51\)](#)
- [Viewing the valid processor values for a DB instance class \(p. 52\)](#)
- [Returning to default processor settings for a DB instance \(p. 53\)](#)
- [Returning to the default number of CPU cores for a DB instance \(p. 53\)](#)
- [Returning to the default number of threads per core for a DB instance \(p. 54\)](#)

Setting the number of CPU cores for a DB instance

Example

The following example modifies `mydbinstance` by setting the number of CPU cores to 4. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--processor-features "Name=coreCount,Value=4" \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--processor-features "Name=coreCount,Value=4" ^
--apply-immediately
```

Setting the number of CPU cores and disabling multiple threads for a DB instance

Example

The following example modifies `mydbinstance` by setting the number of CPU cores to 4 and disabling multiple threads per core. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--processor-features "Name=coreCount,Value=4" "Name=threadsPerCore,Value=1" \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--processor-features "Name=coreCount,Value=4" "Name=threadsPerCore,Value=1" ^
--apply-immediately
```

Viewing the valid processor values for a DB instance class

Example

You can view the valid processor values for a particular DB instance class by running the [describe-orderable-db-instance-options](#) command and specifying the instance class for the --db-instance-class option. For example, the output for the following command shows the processor options for the db.r3.large instance class.

```
aws rds describe-orderable-db-instance-options --engine oracle-ee --db-instance-class db.r3.large
```

Following is sample output for the command in JSON format.

```
{
    "SupportsIops": true,
    "MaxIopsPerGib": 50.0,
    "LicenseModel": "bring-your-own-license",
    "DBInstanceClass": "db.r3.large",
    "SupportsIAMDatabaseAuthentication": false,
    "MinStorageSize": 100,
    "AvailabilityZones": [
        {
            "Name": "us-west-2a"
        },
        {
            "Name": "us-west-2b"
        },
        {
            "Name": "us-west-2c"
        }
    ],
    "EngineVersion": "12.1.0.2.v2",
    "MaxStorageSize": 32768,
    "MinIopsPerGib": 1.0,
    "MaxIopsPerDbInstance": 40000,
    "ReadReplicaCapable": false,
    "AvailableProcessorFeatures": [
        {
            "Name": "coreCount",
            "DefaultValue": "1",
            "AllowedValues": "1"
        },
        {
            "Name": "threadsPerCore",
            "DefaultValue": "2",
            "AllowedValues": "1,2"
        }
    ]
},
```

```
        "SupportsEnhancedMonitoring": true,  
        "SupportsPerformanceInsights": false,  
        "MinIopsPerDbInstance": 1000,  
        "StorageType": "io1",  
        "Vpc": false,  
        "SupportsStorageEncryption": true,  
        "Engine": "oracle-ee",  
        "MultiAZCapable": true  
    }
```

In addition, you can run the following commands for DB instance class processor information:

- [describe-db-instances](#) – Shows the processor information for the specified DB instance.
- [describe-db-snapshots](#) – Shows the processor information for the specified DB snapshot.
- [describe-valid-db-instance-modifications](#) – Shows the valid modifications to the processor for the specified DB instance.

In the output of the preceding commands, the values for the processor features are not null only if the following conditions are met:

- You are using an Oracle DB instance.
- Your Oracle DB instance supports changing processor values.
- The current CPU core and thread settings are set to nondefault values.

If the preceding conditions aren't met, you can get the instance type using [describe-db-instances](#). You can get the processor information for this instance type by running the EC2 operation [describe-instance-types](#).

Returning to default processor settings for a DB instance

Example

The following example modifies mydbinstance by returning its DB instance class to the default processor values for it. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --use-default-processor-features \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --use-default-processor-features ^  
  --apply-immediately
```

Returning to the default number of CPU cores for a DB instance

Example

The following example modifies mydbinstance by returning its DB instance class to the default number of CPU cores for it. The threads per core setting isn't changed. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--processor-features "Name=coreCount,Value=DEFAULT" \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--processor-features "Name=coreCount,Value=DEFAULT" ^
--apply-immediately
```

Returning to the default number of threads per core for a DB instance

Example

The following example modifies mydbinstance by returning its DB instance class to the default number of threads per core for it. The number of CPU cores setting isn't changed. The changes are applied immediately by using --apply-immediately. If you want to apply the changes during the next scheduled maintenance window, omit the --apply-immediately option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--processor-features "Name=threadsPerCore,Value=DEFAULT" \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--processor-features "Name=threadsPerCore,Value=DEFAULT" ^
--apply-immediately
```

RDS API

You can set the processor features for a DB instance when you call one of the following Amazon RDS API operations:

- [CreateDBInstance](#)
- [ModifyDBInstance](#)
- [RestoreDBInstanceFromDBSnapshot](#)
- [RestoreDBInstanceFromS3](#)
- [RestoreDBInstanceToPointInTime](#)

To configure the processor features of a DB instance class for a DB instance by using the Amazon RDS API, include the `ProcessFeatures` parameter in the call.

The parameter has the following syntax.

```
ProcessFeatures "Name=coreCount,Value=<value>" "Name=threadsPerCore,Value=<value>"
```

Specify the number of CPU cores with the `coreCount` feature name, and specify whether multiple threads per core are enabled with the `threadsPerCore` feature name.

You can view the valid processor values for a particular instance class by running the [DescribeOrderableDBInstanceState](#) operation and specifying the instance class for the `DBInstanceState` parameter. You can also use the following operations:

- [DescribeDBInstances](#) – Shows the processor information for the specified DB instance.
- [DescribeDBSnapshots](#) – Shows the processor information for the specified DB snapshot.
- [DescribeValidDBInstanceModifications](#) – Shows the valid modifications to the processor for the specified DB instance.

In the output of the preceding operations, the values for the processor features are not null only if the following conditions are met:

- You are using an Oracle DB instance.
- Your Oracle DB instance supports changing processor values.
- The current CPU core and thread settings are set to nondefault values.

If the preceding conditions aren't met, you can get the instance type using [DescribeDBInstances](#). You can get the processor information for this instance type by running the EC2 operation [DescribeInstanceTypes](#).

Hardware specifications for DB instance classes

The following terminology is used to describe hardware specifications for DB instance classes:

vCPU

The number of virtual central processing units (CPUs). A *virtual CPU* is a unit of capacity that you can use to compare DB instance classes. Instead of purchasing or leasing a particular processor to use for several months or years, you are renting capacity by the hour. Our goal is to make a consistent and specific amount of CPU capacity available, within the limits of the actual underlying hardware.

ECU

The relative measure of the integer processing power of an Amazon EC2 instance. To make it easy for developers to compare CPU capacity between different instance classes, we have defined an Amazon EC2 Compute Unit. The amount of CPU that is allocated to a particular instance is expressed in terms of these EC2 Compute Units. One ECU currently provides CPU capacity equivalent to a 1.0–1.2 GHz 2007 Opteron or 2007 Xeon processor.

Memory (GiB)

The RAM, in gibibytes, allocated to the DB instance. There is often a consistent ratio between memory and vCPU. As an example, take the db.r4 instance class, which has a memory to vCPU ratio similar to the db.r5 instance class. However, for most use cases the db.r5 instance class provides better, more consistent performance than the db.r4 instance class.

EBS-Optimized

The DB instance uses an optimized configuration stack and provides additional, dedicated capacity for I/O. This optimization provides the best performance by minimizing contention between I/O and other traffic from your instance. For more information about Amazon EBS-optimized instances, see [Amazon EBS-Optimized instances](#) in the *Amazon EC2 User Guide for Linux Instances*.

Max. Bandwidth (Mbps)

The maximum bandwidth in megabits per second. Divide by 8 to get the expected throughput in megabytes per second.

Important

General Purpose SSD (gp2) volumes for Amazon RDS DB instances have a throughput limit of 250 MiB/s in most cases. However, the throughput limit can vary depending on volume size. For more information, see [Amazon EBS volume types](#) in the *Amazon EC2 User Guide for Linux Instances*.

Network Performance

The network speed relative to other DB instance classes.

In the following table, you can find hardware details about the Amazon RDS DB instance classes.

For information about Amazon RDS DB engine support for each DB instance class, see [Supported DB engines for DB instance classes \(p. 12\)](#).

Instance class	vCPU	ECU	Memory (GiB)	EBS optimized	Max. bandwidth (mbps)	Network performance	
db.m6g – general-purpose instance classes powered by AWS Graviton2 processors							
db.m6g.16xlarge	64	—	256	Yes	19,000	25 Gbps	
db.m6g.12xlarge	48	—	192	Yes	13,500	20 Gbps	
db.m6g.8xlarge	32	—	128	Yes	9,500	12 Gbps	
db.m6g.4xlarge	16	—	64	Yes	6,800	Up to 10 Gbps	
db.m6g.2xlarge*	8	—	32	Yes	Up to 4,750	Up to 10 Gbps	
db.m6g.xlarge*	4	—	16	Yes	Up to 4,750	Up to 10 Gbps

db.t2.small	1	Variable	2	No	—	Low	
db.t2.micro	1	Variable	1	No	—	Low	

* These DB instance classes can support maximum performance for 30 minutes at least once every 24 hours. For more information on baseline performance of these instance types, see [Amazon EBS-optimized instances](#) in the *Amazon EC2 User Guide for Linux Instances*.

** The r3.8xlarge instance doesn't have dedicated EBS bandwidth and therefore doesn't offer EBS optimization. On this instance, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

Amazon RDS DB instance storage

DB instances for Amazon RDS for MySQL, MariaDB, PostgreSQL, Oracle, and Microsoft SQL Server use Amazon Elastic Block Store (Amazon EBS) volumes for database and log storage. Depending on the amount of storage requested, Amazon RDS automatically stripes across multiple Amazon EBS volumes to enhance performance.

For more information about instance storage pricing, see [Amazon RDS pricing](#).

Amazon RDS storage types

Amazon RDS provides three storage types: General Purpose SSD (also known as gp2 and gp3), Provisioned IOPS SSD (also known as io1), and magnetic (also known as standard). They differ in performance characteristics and price, which means that you can tailor your storage performance and cost to the needs of your database workload. You can create MySQL, MariaDB, Oracle, and PostgreSQL RDS DB instances with up to 64 tebibytes (TiB) of storage. You can create SQL Server RDS DB instances with up to 16 TiB of storage. For this amount of storage, use the Provisioned IOPS SSD and General Purpose SSD storage types.

The following list briefly describes the three storage types:

- **General Purpose SSD** – General Purpose SSD volumes offer cost-effective storage that is ideal for a broad range of workloads running on medium-sized DB instances. General Purpose storage is best suited for development and testing environments.

For more information about General Purpose SSD storage, including the storage size ranges, see [General Purpose SSD storage \(p. 64\)](#).

- **Provisioned IOPS SSD** – Provisioned IOPS storage is designed to meet the needs of I/O-intensive workloads, particularly database workloads, that require low I/O latency and consistent I/O throughput. Provisioned IOPS storage is best suited for production environments.

For more information about Provisioned IOPS storage, including the storage size ranges, see [Provisioned IOPS SSD storage \(p. 66\)](#).

- **Magnetic** – Amazon RDS also supports magnetic storage for backward compatibility. We recommend that you use General Purpose SSD or Provisioned IOPS SSD for any new storage needs. The maximum amount of storage allowed for DB instances on magnetic storage is less than that of the other storage types. For more information, see [Magnetic storage \(p. 68\)](#).

General Purpose SSD storage

General Purpose SSD storage offers cost-effective storage that is acceptable for most database workloads that aren't latency sensitive. The following are the storage size ranges for General Purpose SSD DB instances:

- MariaDB, MySQL, Oracle, and PostgreSQL database instances: 20 GiB–64 TiB
- SQL Server Enterprise, Standard, Web, and Express Editions: 20 GiB–16 TiB

Note

DB instances that use General Purpose SSD storage can experience much longer latency after read replica creation, Multi-AZ conversion, and DB snapshot restoration than instances that use Provisioned IOPS storage. If you need a DB instance with minimum latency after these operations, we recommend using [Provisioned IOPS SSD storage \(p. 66\)](#).

Amazon RDS offers two types of General Purpose SSD storage: [gp2 storage \(p. 65\)](#) and [gp3 storage \(p. 65\)](#).

gp2 storage

When your applications don't need high storage performance, you can use General Purpose SSD gp2 storage. Baseline I/O performance for gp2 storage is 3 IOPS for each GiB, with a minimum of 100 IOPS. This relationship means that larger volumes have better performance. For example, baseline performance for a 100-GiB volume is 300 IOPS. Baseline performance for a 1-TiB volume is 3,000 IOPS. Maximum baseline performance for a gp2 volume (5.34 TiB and greater) is 16,000 IOPS.

Volumes below 1 TiB in size also have the ability to burst to 3,000 IOPS for extended periods of time. Instance I/O credit balance determines burst performance. For more information about instance I/O credits, see [I/O credits and burst performance](#) in the *Amazon EC2 User Guide*. For a more detailed description of how baseline performance and I/O credit balance affect performance, see the post [Understanding burst vs. baseline performance with Amazon RDS and gp2](#) on the AWS Database Blog.

Many workloads never deplete the burst balance. However, some workloads can exhaust the 3,000 IOPS burst storage credit balance, so you should plan your storage capacity to meet the needs of your workloads.

For gp2 volumes larger than 1 TiB, the baseline performance is greater than the burst performance. For such volumes, burst is often irrelevant because the baseline performance is better than the 3,000 IOPS burst performance. However, for DB instances larger than 1 TiB where the storage is *striped* across four Amazon EBS volumes, burst performance of up to 12,000 IOPS can be seen. This applies to RDS database engines other than Microsoft SQL Server, which doesn't support volume striping.

gp3 storage

By using General Purpose SSD gp3 storage volumes, you can customize storage performance independently of storage capacity. *Storage performance* is the combination of I/O operations per second (IOPS) and how fast the storage volume can perform reads and writes (storage throughput). On gp3 storage volumes, Amazon RDS provides a baseline storage performance of 3000 IOPS and 125 MiBps.

For every RDS DB engine except RDS for SQL Server, when the storage size for gp3 volumes reaches a certain threshold, the baseline storage performance increases to 12,000 IOPS and 500 MiBps. This is because of *volume striping*, where the storage uses four logical volumes instead of one. RDS for SQL Server doesn't support volume striping, and therefore doesn't have a threshold value.

Note

General Purpose SSD gp3 storage is supported on Single-AZ and Multi-AZ DB instances, but isn't supported on Multi-AZ DB clusters. For more information, see [Multi-AZ deployments for high availability \(p. 121\)](#) and [Multi-AZ DB cluster deployments \(p. 127\)](#).

Storage performance for gp3 volumes on Amazon RDS DB engines, including the threshold, is shown in the following table.

DB engine	Storage size	Baseline storage performance	Range of Provisioned IOPS	Range of provisioned storage throughput
MariaDB, MySQL, and PostgreSQL	Less than 400 GiB	3,000 IOPS/125 MiBps	N/A	N/A
MariaDB, MySQL, and PostgreSQL	400 GiB and higher	12,000 IOPS/500 MiBps	12,000–64,000 IOPS	500–4,000 MiBps
Oracle	Less than 200 GiB	3,000 IOPS/125 MiBps	N/A	N/A

DB engine	Storage size	Baseline storage performance	Range of Provisioned IOPS	Range of provisioned storage throughput
Oracle	200 GiB and higher	12,000 IOPS/500 MiBps	12,000–64,000 IOPS	500–4,000 MiBps
SQL Server	20 GiB–16 TiB	3,000 IOPS/125 MiBps	3,000–16,000 IOPS	125–1,000 MiBps

For every DB engine except RDS for SQL Server, you can provision additional IOPS and storage throughput when storage size is at or above the threshold value. For RDS for SQL Server, you can provision additional IOPS and storage throughput for any available storage size. For all DB engines, you pay for only the additional provisioned storage performance. For more information, see [Amazon RDS pricing](#).

Although the added Provisioned IOPS and storage throughput aren't dependent on the storage size, they are related to each other. When you raise the IOPS above 32,000 for MariaDB and MySQL, the storage throughput value automatically increases from 500 MiBps. For example, when you set the IOPS to 40,000 on RDS for MySQL, the storage throughput must be at least 625 MiBps. The automatic increase doesn't happen for Oracle, PostgreSQL, and SQL Server DB instances.

Storage performance values for gp3 volumes on RDS have the following constraints:

- The maximum ratio of storage throughput to IOPS is 0.25 for all supported DB engines.
- The minimum ratio of IOPS to allocated storage (in GiB) is 0.5 on RDS for SQL Server. There is no minimum ratio for the other supported DB engines.
- The maximum ratio of IOPS to allocated storage is 500 for all supported DB engines.
- If you're using storage autoscaling, the same ratios between IOPS and maximum storage threshold (in GiB) also apply.

For more information on storage autoscaling, see [Managing capacity automatically with Amazon RDS storage autoscaling \(p. 412\)](#).

Provisioned IOPS SSD storage

For a production application that requires fast and consistent I/O performance, we recommend Provisioned IOPS (I/O operations per second) storage. Provisioned IOPS storage is a storage type that delivers predictable performance, and consistently low latency. Provisioned IOPS storage is optimized for online transaction processing (OLTP) workloads that have consistent performance requirements. Provisioned IOPS helps performance tuning of these workloads.

In some cases, your database workload might not be able to achieve 100 percent of the IOPS that you have provisioned. For more information, see [Factors that affect storage performance \(p. 69\)](#).

When you create a DB instance, you specify the IOPS rate and the size of the volume. Amazon RDS provides that IOPS rate for the DB instance until you change it.

io1 storage

For I/O-intensive workloads, you can use Provisioned IOPS SSD io1 storage and achieve up to 256,000 I/O operations per second (IOPS). The following table shows the range of Provisioned IOPS and storage size for each database engine.

Database engine	Range of Provisioned IOPS	Range of storage size
MariaDB	1,000–256,000 IOPS	100 GiB–64 TiB
SQL Server	1,000–64,000 IOPS	20 GiB–16 TiB
MySQL	1,000–256,000 IOPS	100 GiB–64 TiB
Oracle	1,000–256,000 IOPS	100 GiB–64 TiB
PostgreSQL	1,000–256,000 IOPS	100 GiB–64 TiB

Note

For SQL Server, the maximum 64,000 IOPS is guaranteed only on [Nitro-based instances](#) that are on the m5*, m6i, r5*, r6i, and z1d instance types. Other instance types guarantee performance up to 32,000 IOPS.

For Oracle, you can provision the maximum 256,000 IOPS only on the r5b instance type.

The IOPS and storage size ranges have the following constraints:

- The ratio of IOPS to allocated storage (in GiB) must be from 1–50 on RDS for SQL Server, and 0.5–50 on other RDS DB engines.
- If you're using storage autoscaling, the same ratios between IOPS and maximum storage threshold (in GiB) also apply.

For more information on storage autoscaling, see [Managing capacity automatically with Amazon RDS storage autoscaling \(p. 412\)](#).

Combining Provisioned IOPS storage with Multi-AZ deployments or read replicas

For production OLTP use cases, we recommend that you use Multi-AZ deployments for enhanced fault tolerance with Provisioned IOPS storage for fast and predictable performance.

You can also use Provisioned IOPS SSD storage with read replicas for MySQL, MariaDB or PostgreSQL. The type of storage for a read replica is independent of that on the primary DB instance. For example, you might use General Purpose SSD for read replicas with a primary DB instance that uses Provisioned IOPS SSD storage to reduce costs. However, your read replica's performance in this case might differ from that of a configuration where both the primary DB instance and the read replicas use Provisioned IOPS SSD storage.

Provisioned IOPS storage costs

With Provisioned IOPS storage, you are charged for the provisioned resources whether or not you use them in a given month.

For more information about pricing, see [Amazon RDS pricing](#).

Getting the best performance from Amazon RDS Provisioned IOPS SSD storage

If your workload is I/O constrained, using Provisioned IOPS SSD storage can increase the number of I/O requests that the system can process concurrently. Increased concurrency allows for decreased latency

because I/O requests spend less time in a queue. Decreased latency allows for faster database commits, which improves response time and allows for higher database throughput.

Provisioned IOPS SSD storage provides a way to reserve I/O capacity by specifying IOPS. However, as with any other system capacity attribute, its maximum throughput under load is constrained by the resource that is consumed first. That resource might be network bandwidth, CPU, memory, or database internal resources.

For more information about getting the most out of your Provisioned IOPS volumes, see [Amazon EBS volume performance](#).

Comparing solid-state drive (SSD) storage types

The following table shows use cases and performance characteristics for the SSD storage volumes used by Amazon RDS.

Characteristic	Provisioned IOPS (io1)	General Purpose (gp3)	General Purpose (gp2)
Description	Consistent storage performance (IOPS, throughput, latency) Designed for latency-sensitive, transactional workloads.	Flexibility in provisioning storage, IOPS, and throughput independently Balances price performance for a wide variety of transactional workloads	Provides burstable IOPS Balances price performance for a wide variety of transactional workloads
Use cases	Transactional workloads that require sustained IOPS performance up to 256,000 IOPS	Broad range of workloads running on medium-sized relational databases in development/test environments	Broad range of workloads running on medium-sized relational databases in development/test environments
Latency	Single-digit millisecond, provided consistently 99.9% of the time	Single-digit millisecond, provided consistently 99% of the time	Single-digit millisecond, provided consistently 99% of the time
Volume size	100 GiB–64 TiB (16 TiB on RDS for SQL Server)	20 GiB–64 TiB (16 TiB on RDS for SQL Server)	20 GiB–64 TiB (16 TiB on RDS for SQL Server)
Maximum IOPS	256,000 (64,000 on RDS for SQL Server)	64,000 (16,000 on RDS for SQL Server)	16,000
Maximum throughput	Scales based on Provisioned IOPS up to 4,000 MB/s	Provision additional throughput up to 4,000 MB/s	250 MB/s
AWS CLI and RDS API name	io1	gp3	gp2

Magnetic storage

Amazon RDS also supports magnetic storage for backward compatibility. We recommend that you use General Purpose SSD or Provisioned IOPS SSD for any new storage needs. The following are some limitations for magnetic storage:

- Doesn't allow you to scale storage when using the SQL Server database engine.
- Doesn't support storage autoscaling.
- Doesn't support elastic volumes.
- Limited to a maximum size of 3 TiB.
- Limited to a maximum of 1,000 IOPS.

Monitoring storage performance

Amazon RDS provides several metrics that you can use to determine how your DB instance is performing. You can view the metrics on the summary page for your instance in Amazon RDS Management Console. You can also use Amazon CloudWatch to monitor these metrics. For more information, see [Viewing metrics in the Amazon RDS console \(p. 525\)](#). Enhanced Monitoring provides more detailed I/O metrics; for more information, see [Monitoring OS metrics with Enhanced Monitoring \(p. 600\)](#).

The following metrics are useful for monitoring storage for your DB instance:

- **IOPS** – The number of I/O operations completed each second. This metric is reported as the average IOPS for a given time interval. Amazon RDS reports read and write IOPS separately on 1-minute intervals. Total IOPS is the sum of the read and write IOPS. Typical values for IOPS range from zero to tens of thousands per second.
- **Latency** – The elapsed time between the submission of an I/O request and its completion. This metric is reported as the average latency for a given time interval. Amazon RDS reports read and write latency separately at 1-minute intervals. Typical values for latency are in milliseconds (ms).
- **Throughput** – The number of bytes each second that are transferred to or from disk. This metric is reported as the average throughput for a given time interval. Amazon RDS reports read and write throughput separately on 1-minute intervals using units of megabytes per second (MB/s). Typical values for throughput range from zero to the I/O channel's maximum bandwidth.
- **Queue Depth** – The number of I/O requests in the queue waiting to be serviced. These are I/O requests that have been submitted by the application but have not been sent to the device because the device is busy servicing other I/O requests. Time spent waiting in the queue is a component of latency and service time (not available as a metric). This metric is reported as the average queue depth for a given time interval. Amazon RDS reports queue depth in 1-minute intervals. Typical values for queue depth range from zero to several hundred.

Measured IOPS values are independent of the size of the individual I/O operation. This means that when you measure I/O performance, make sure to look at the throughput of the instance, not simply the number of I/O operations.

Factors that affect storage performance

System activities, database workload, and DB instance class can affect storage performance.

System activities

The following system-related activities consume I/O capacity and might reduce DB instance performance while in progress:

- Multi-AZ standby creation
- Read replica creation
- Changing storage types

Database workload

In some cases, your database or application design results in concurrency issues, locking, or other forms of database contention. In these cases, you might not be able to use all the provisioned bandwidth directly. In addition, you might encounter the following workload-related situations:

- The throughput limit of the underlying instance type is reached.
- Queue depth is consistently less than 1 because your application isn't driving enough I/O operations.
- You experience query contention in the database even though some I/O capacity is unused.

In some cases, there isn't a system resource that is at or near a limit, and adding threads doesn't increase the database transaction rate. In such cases, the bottleneck is most likely contention in the database. The most common forms are row lock and index page lock contention, but there are many other possibilities. If this is your situation, seek the advice of a database performance tuning expert.

DB instance class

To get the most performance out of your Amazon RDS DB instance, choose a current generation instance type with enough bandwidth to support your storage type. For example, you can choose Amazon EBS-optimized instances and instances with 10-gigabit network connectivity.

Important

Depending on the instance class you're using, you might see lower IOPS performance than the maximum that you can provision with RDS. For specific information on IOPS performance for DB instance classes, see [Amazon EBS-optimized instances](#) in the *Amazon EC2 User Guide*.

We recommend that you determine the maximum IOPS for the instance class before setting a Provisioned IOPS value for your DB instance.

We encourage you to use the latest generation of instances to get the best performance. Previous generation DB instances can also have lower maximum storage.

Some older 32-bit file systems might have lower storage capacities. To determine the storage capacity of your DB instance, you can use the [describe-valid-db-instance-modifications](#) AWS CLI command.

The following list shows the maximum storage that most DB instance classes can scale to for each database engine:

- MariaDB – 64 TiB
- Microsoft SQL Server – 16 TiB
- MySQL – 64 TiB
- Oracle – 64 TiB
- PostgreSQL – 64 TiB

The following table shows some exceptions for maximum storage (in TiB). All RDS for Microsoft SQL Server DB instances have a maximum storage of 16 TiB, so there are no entries for SQL Server.

Instance class	MariaDB	MySQL	Oracle	PostgreSQL
db.m3 – standard instance classes				
db.m3.2xlarge	N/A	6	N/A	6
db.m3.xlarge	N/A	6	N/A	6
db.m3.large	N/A	6	N/A	6

Instance class	MariaDB	MySQL	Oracle	PostgreSQL
db.m3.medium	N/A	32	N/A	32
db.t4g – burstable-performance instance classes				
db.t4g.medium	16	16	N/A	32
db.t4g.small	16	16	N/A	16
db.t4g.micro	6	6	N/A	6
db.t3 – burstable-performance instance classes				
db.t3.medium	16	16	32	32
db.t3.small	16	16	32	16
db.t3.micro	6	6	32	6
db.t2 – burstable-performance instance classes				
db.t2.medium	32	32	N/A	32
db.t2.small	16	16	N/A	16
db.t2.micro	6	6	N/A	6

For more details about all instance classes supported, see [Previous generation DB instances](#).

Regions, Availability Zones, and Local Zones

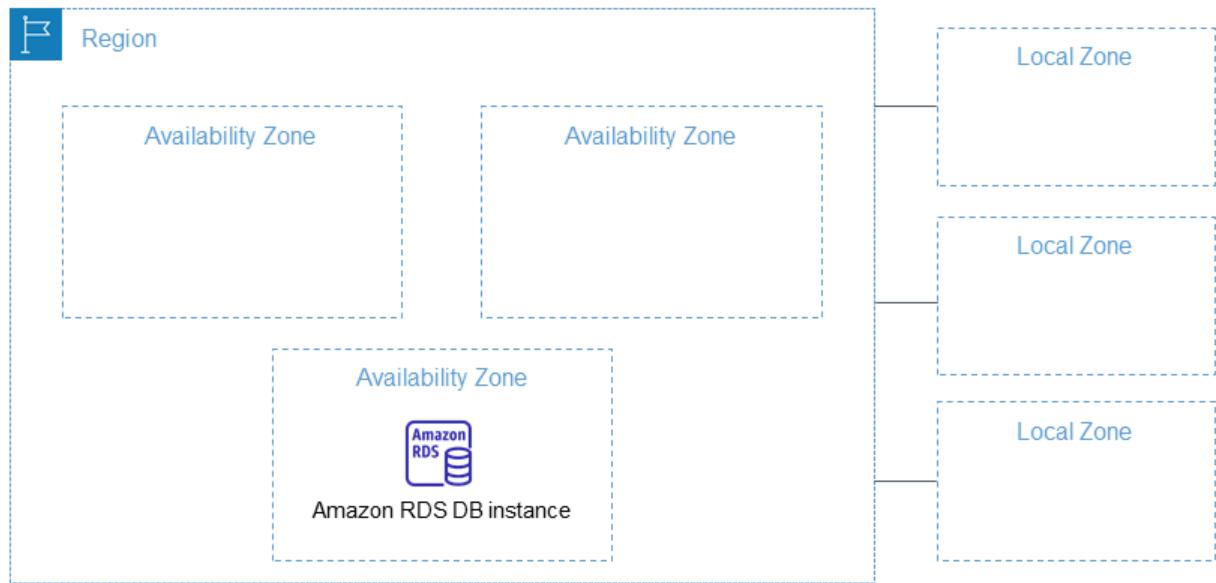

Amazon cloud computing resources are hosted in multiple locations world-wide. These locations are composed of AWS Regions, Availability Zones, and Local Zones. Each *AWS Region* is a separate geographic area. Each AWS Region has multiple, isolated locations known as *Availability Zones*.

Note

For information about finding the Availability Zones for an AWS Region, see [Describe your Availability Zones](#) in the Amazon EC2 documentation.

By using Local Zones, you can place resources, such as compute and storage, in multiple locations closer to your users. Amazon RDS enables you to place resources, such as DB instances, and data in multiple locations. Resources aren't replicated across AWS Regions unless you do so specifically.

Amazon operates state-of-the-art, highly-available data centers. Although rare, failures can occur that affect the availability of DB instances that are in the same location. If you host all your DB instances in one location that is affected by such a failure, none of your DB instances will be available.

It is important to remember that each AWS Region is completely independent. Any Amazon RDS activity you initiate (for example, creating database instances or listing available database instances) runs only in your current default AWS Region. The default AWS Region can be changed in the console, or by setting the `AWS_DEFAULT_REGION` environment variable. Or it can be overridden by using the `--region` parameter with the AWS Command Line Interface (AWS CLI). For more information, see [Configuring the AWS Command Line Interface](#), specifically the sections about environment variables and command line options.

Amazon RDS supports special AWS Regions called AWS GovCloud (US). These are designed to allow US government agencies and customers to move more sensitive workloads into the cloud. The AWS GovCloud (US) Regions address the US government's specific regulatory and compliance requirements. For more information, see [What is AWS GovCloud \(US\)?](#)

To create or work with an Amazon RDS DB instance in a specific AWS Region, use the corresponding regional service endpoint.

AWS Regions

Each AWS Region is designed to be isolated from the other AWS Regions. This design achieves the greatest possible fault tolerance and stability.

When you view your resources, you see only the resources that are tied to the AWS Region that you specified. This is because AWS Regions are isolated from each other, and we don't automatically replicate resources across AWS Regions.

Region availability

The following table shows the AWS Regions where Amazon RDS is currently available and the endpoint for each Region.

Region Name	Region	Endpoint	Protocol	
US East (Ohio)	us-east-2	rds.us-east-2.amazonaws.com	HTTPS	
		rds-fips.us-east-2.api.aws	HTTPS	
		rds.us-east-2.api.aws	HTTPS	
		rds-fips.us-east-2.amazonaws.com	HTTPS	
US East (N. Virginia)	us-east-1	rds.us-east-1.amazonaws.com	HTTPS	
		rds-fips.us-east-1.api.aws	HTTPS	
		rds-fips.us-east-1.amazonaws.com	HTTPS	
		rds.us-east-1.api.aws	HTTPS	
US West (N. California)	us-west-1	rds.us-west-1.amazonaws.com	HTTPS	
		rds.us-west-1.api.aws	HTTPS	
		rds-fips.us-west-1.amazonaws.com	HTTPS	
		rds-fips.us-west-1.api.aws	HTTPS	
US West (Oregon)	us-west-2	rds.us-west-2.amazonaws.com	HTTPS	
		rds-fips.us-west-2.amazonaws.com	HTTPS	
		rds.us-west-2.api.aws	HTTPS	
		rds-fips.us-west-2.api.aws	HTTPS	
Africa (Cape Town)	af-south-1	rds.af-south-1.amazonaws.com	HTTPS	
		rds.af-south-1.api.aws	HTTPS	
Asia Pacific (Hong Kong)	ap-east-1	rds.ap-east-1.amazonaws.com	HTTPS	
		rds.ap-east-1.api.aws	HTTPS	

Region Name	Region	Endpoint	Protocol	
Asia Pacific (Hyderabad)	ap-south-2	rds.ap-south-2.amazonaws.com	HTTPS	
Asia Pacific (Jakarta)	ap-southeast-3	rds.ap-southeast-3.amazonaws.com	HTTPS	
Asia Pacific (Mumbai)	ap-south-1	rds.ap-south-1.amazonaws.com rds.ap-south-1.api.aws	HTTPS HTTPS	
Asia Pacific (Osaka)	ap-northeast-3	rds.ap-northeast-3.amazonaws.com rds.ap-northeast-3.api.aws	HTTPS HTTPS	
Asia Pacific (Seoul)	ap-northeast-2	rds.ap-northeast-2.amazonaws.com rds.ap-northeast-2.api.aws	HTTPS HTTPS	
Asia Pacific (Singapore)	ap-southeast-1	rds.ap-southeast-1.amazonaws.com rds.ap-southeast-1.api.aws	HTTPS HTTPS	
Asia Pacific (Sydney)	ap-southeast-2	rds.ap-southeast-2.amazonaws.com rds.ap-southeast-2.api.aws	HTTPS HTTPS	
Asia Pacific (Tokyo)	ap-northeast-1	rds.ap-northeast-1.amazonaws.com rds.ap-northeast-1.api.aws	HTTPS HTTPS	
Canada (Central)	ca-central-1	rds.ca-central-1.amazonaws.com rds.ca-central-1.api.aws rds-fips.ca-central-1.api.aws rds-fips.ca-central-1.amazonaws.com	HTTPS HTTPS HTTPS HTTPS	
Europe (Frankfurt)	eu-central-1	rds.eu-central-1.amazonaws.com rds.eu-central-1.api.aws	HTTPS HTTPS	
Europe (Ireland)	eu-west-1	rds.eu-west-1.amazonaws.com rds.eu-west-1.api.aws	HTTPS HTTPS	
Europe (London)	eu-west-2	rds.eu-west-2.amazonaws.com rds.eu-west-2.api.aws	HTTPS HTTPS	
Europe (Milan)	eu-south-1	rds.eu-south-1.amazonaws.com rds.eu-south-1.api.aws	HTTPS HTTPS	

Region Name	Region	Endpoint	Protocol	
Europe (Paris)	eu-west-3	rds.eu-west-3.amazonaws.com rds.eu-west-3.api.aws	HTTPS HTTPS	
Europe (Spain)	eu-south-2	rds.eu-south-2.amazonaws.com	HTTPS	
Europe (Stockholm)	eu-north-1	rds.eu-north-1.amazonaws.com rds.eu-north-1.api.aws	HTTPS HTTPS	
Europe (Zurich)	eu-central-2	rds.eu-central-2.amazonaws.com	HTTPS	
Middle East (Bahrain)	me-south-1	rds.me-south-1.amazonaws.com rds.me-south-1.api.aws	HTTPS HTTPS	
Middle East (UAE)	me-central-1	rds.me-central-1.amazonaws.com	HTTPS	
South America (São Paulo)	sa-east-1	rds.sa-east-1.amazonaws.com rds.sa-east-1.api.aws	HTTPS HTTPS	
AWS GovCloud (US-East)	us-gov-east-1	rds.us-gov-east-1.amazonaws.com	HTTPS	
AWS GovCloud (US-West)	us-gov-west-1	rds.us-gov-west-1.amazonaws.com	HTTPS	

If you do not explicitly specify an endpoint, the US West (Oregon) endpoint is the default.

When you work with a DB instance using the AWS CLI or API operations, make sure that you specify its regional endpoint.

Availability Zones

When you create a DB instance, you can choose an Availability Zone or have Amazon RDS choose one for you randomly. An Availability Zone is represented by an AWS Region code followed by a letter identifier (for example, us-east-1a).

You can't choose the Availability Zones for the primary and secondary DB instances in a Multi-AZ DB deployment. Amazon RDS chooses them for you randomly. For more information about Multi-AZ deployments, see [Multi-AZ deployments for high availability \(p. 121\)](#).

Note

Random selection of Availability Zones by RDS doesn't guarantee an even distribution of DB instances among Availability Zones within a single account or DB subnet group. You can request a specific AZ when you create or modify a Single-AZ instance, and you can use more-specific DB subnet groups for Multi-AZ instances. For more information, see [Creating an Amazon RDS DB instance \(p. 230\)](#) and [Modifying an Amazon RDS DB instance \(p. 327\)](#).

Local Zones

A *Local Zone* is an extension of an AWS Region that is geographically close to your users. You can extend any VPC from the parent AWS Region into Local Zones. To do so, create a new subnet and assigning it to the AWS Local Zone. When you create a subnet in a Local Zone, your VPC is extended to that Local Zone. The subnet in the Local Zone operates the same as other subnets in your VPC.

When you create a DB instance, you can choose a subnet in a Local Zone. Local Zones have their own connections to the internet and support AWS Direct Connect. Thus, resources created in a Local Zone can serve local users with very low-latency communications. For more information, see [AWS Local Zones](#).

A Local Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example us-west-2-lax-1a.

Note

A Local Zone can't be included in a Multi-AZ deployment.

To use a Local Zone

1. Enable the Local Zone in the Amazon EC2 console.

For more information, see [Enabling Local Zones in the Amazon EC2 User Guide for Linux Instances](#).

2. Create a subnet in the Local Zone.

For more information, see [Creating a subnet in your VPC](#) in the *Amazon VPC User Guide*.

3. Create a DB subnet group in the Local Zone.

When you create a DB subnet group, choose the Availability Zone group for the Local Zone.

For more information, see [Creating a DB instance in a VPC \(p. 2111\)](#).

4. Create a DB instance that uses the DB subnet group in the Local Zone.

For more information, see [Creating an Amazon RDS DB instance \(p. 230\)](#).

Important

Currently, the only AWS Local Zone where Amazon RDS is available is Los Angeles in the US West (Oregon) Region.

Supported features in Amazon RDS by AWS Region and DB engine

Support for Amazon RDS features and options varies across AWS Regions and specific versions of each DB engine. To identify RDS DB engine version support and availability in a given AWS Region, you can use the following sections.

Amazon RDS features are different from engine-native features and options. For more information on engine-native features and options, see [Engine-native features. \(p. 120\)](#)

Topics

- [Table conventions \(p. 77\)](#)
- [Feature quick reference \(p. 77\)](#)
- [Cross-Region automated backups \(p. 78\)](#)
- [Cross-Region read replicas \(p. 83\)](#)
- [Database activity streams \(p. 85\)](#)
- [Dual-stack mode \(p. 88\)](#)
- [Export snapshots to S3 \(p. 95\)](#)
- [IAM database authentication \(p. 99\)](#)
- [Kerberos authentication \(p. 101\)](#)
- [Multi-AZ DB clusters \(p. 107\)](#)
- [Performance Insights \(p. 110\)](#)
- [RDS Custom \(p. 110\)](#)
- [Amazon RDS Proxy \(p. 114\)](#)
- [Engine-native features \(p. 120\)](#)

Table conventions

The tables in the feature sections use these patterns to specify version numbers and level of support:

- **Version x.y** – The specific version alone is supported.
- **Version x.y and higher** – The version and all higher minor versions are supported. For example, "version 10.11 and higher" means that versions 10.11, 10.11.1, and 10.12 are supported.
- – – The feature isn't currently available for that particular RDS feature for the given RDS DB engine, or in that specific AWS Region.

Feature quick reference

The following quick reference table lists each feature and supported RDS DB engine. Region and specific version availability appears in the later feature sections.

Feature	RDS for MariaDB	RDS for MySQL	RDS for Oracle	RDS for PostgreSQL	RDS for SQL Server
Cross-Region	–	–	Available (p. 79)	Available (p. 80)	Available (p. 82)

Feature	RDS for MariaDB	RDS for MySQL	RDS for Oracle	RDS for PostgreSQL	RDS for SQL Server
automated backups					
Cross-Region read replicas	Available (p. 84)				
Database activity streams	–	–	Available (p. 85)	–	–
Dual-stack mode	Available (p. 88)	Available (p. 90)	Available (p. 91)	Available (p. 92)	Available (p. 93)
Export Snapshot to Amazon S3	Available (p. 95)	Available (p. 96)	–	Available (p. 97)	–
AWS Identity and Access Management (IAM) database authentication	Available (p. 99)	Available (p. 101)	–	Available (p. 101)	–
Kerberos authentication	–	Available (p. 102)	Available (p. 103)	Available (p. 104)	Available (p. 106)
Multi-AZ DB clusters	–	Available (p. 107)	–	Available (p. 109)	–
Performance Insights	Available (p. 110)				
RDS Custom	–	–	Available (p. 111)	–	Available (p. 113)
RDS Proxy	Available (p. 115)	Available (p. 116)	–	Available (p. 117)	Available (p. 119)

Cross-Region automated backups

By using backup replication in Amazon RDS, you can configure your RDS DB instance to replicate snapshots and transaction logs to a destination Region. When backup replication is configured for a DB instance, RDS starts a cross-Region copy of all snapshots and transaction logs when they're ready. For more information, see [Replicating automated backups to another AWS Region \(p. 437\)](#).

Backup replication isn't available with the following engines:

- RDS for MariaDB
- RDS for MySQL

For more information on limitations for source and destination backup Regions, see [Replicating automated backups to another AWS Region \(p. 437\)](#).

Topics

- [Backup replication with RDS for Oracle \(p. 79\)](#)
- [Backup replication with RDS for PostgreSQL \(p. 80\)](#)
- [Backup replication with RDS for SQL Server \(p. 82\)](#)

Backup replication with RDS for Oracle

Following are the supported engines and Region availability for backup replication with RDS for Oracle.

Region	RDS for Oracle 21c	RDS for Oracle 19c	RDS for Oracle 12c
US East (Ohio)	All versions	All versions	Version 12.1.0.2.v10 and higher

Cross-Region read replicas

By using cross-Region read replicas in Amazon RDS, you can create a MariaDB, MySQL, Oracle, PostgreSQL, or SQL Server read replica in a different Region from the source DB instance. For more information about cross-Region read replicas, including source and destination Region considerations, see [Creating a read replica in a different AWS Region \(p. 383\)](#).

Topics

- [Cross-Region read replicas with RDS for MariaDB \(p. 84\)](#)
- [Cross-Region read replicas with RDS for MySQL \(p. 84\)](#)
- [Cross-Region read replicas with RDS for Oracle \(p. 84\)](#)
- [Cross-Region read replicas with RDS for PostgreSQL \(p. 84\)](#)
- [Cross-Region read replicas with RDS for SQL Server \(p. 84\)](#)

Cross-Region read replicas with RDS for MariaDB

Cross-Region read replicas with RDS for MariaDB are available in all Regions for the following versions:

- RDS for MariaDB 10.6 (All versions)
- RDS for MariaDB 10.5 (All versions)
- RDS for MariaDB 10.4 (All versions)
- RDS for MariaDB 10.3 (All versions)

Cross-Region read replicas with RDS for MySQL

Cross-Region read replicas with RDS for MySQL are available in all Regions for the following versions:

- RDS for MySQL 8.0 (All versions)
- RDS for MySQL 5.7 (All versions)

Cross-Region read replicas with RDS for Oracle

Cross-Region read replicas for RDS for Oracle are available in all Regions with the following version limitations:

- For RDS for Oracle 21c, cross-Region read replicas aren't available.
- For RDS for Oracle 19c, cross-Region read replicas are available for instances of Oracle Database 19c that aren't container database (CBD) instances.
- For RDS for Oracle 12c, cross-Region read replicas are available for Oracle Enterprise Edition (EE) of Oracle Database 12c Release 1 (12.1) using 12.1.0.2.v10 and higher 12c releases.

For more information on additional requirements for cross-Region read replicas with RDS for Oracle, see [Considerations for RDS for Oracle replicas \(p. 1631\)](#).

Cross-Region read replicas with RDS for PostgreSQL

Cross-Region read replicas with RDS for PostgreSQL are available in all Regions for the following versions:

- RDS for PostgreSQL 14 (All versions)
- RDS for PostgreSQL 13 (All versions)
- RDS for PostgreSQL 12 (All versions)
- RDS for PostgreSQL 11 (All versions)
- RDS for PostgreSQL 10 (All versions)

Cross-Region read replicas with RDS for SQL Server

Cross-Region read replicas with RDS for SQL Server are available in all Regions except the following:

- Africa (Cape Town)
- Asia Pacific (Jakarta)
- Asia Pacific (Hong Kong)
- China (Beijing)

- China (Ningxia)
- Europe (Milan)
- Middle East (Bahrain)
- Middle East (UAE)

Cross-Region read replicas with RDS for SQL Server are available for the following versions using Microsoft SQL Server Enterprise Edition:

- RDS for SQL Server 2019 (Version 15.00.4073.23 and higher)
- RDS for SQL Server 2017 (Version 14.00.3049.1 and higher)
- RDS for SQL Server 2016 (Version 13.00.5216.0 and higher)

Database activity streams

By using Database Activity Streams in Amazon RDS, you can monitor and set alarms for auditing activity in your Oracle database. For more information, see [Overview of Database Activity Streams \(p. 729\)](#).

Database activity streams aren't available with the following engines:

- RDS for MariaDB
- RDS for MySQL
- RDS for PostgreSQL
- RDS for SQL Server

Export snapshots to S3

You can export RDS DB snapshot data to an Amazon S3 bucket. You can export all types of DB snapshots—including manual snapshots, automated system snapshots, and snapshots created by AWS Backup. After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information, see [Exporting DB snapshot data to Amazon S3 \(p. 481\)](#).

IAM database authentication

By using IAM database authentication in Amazon RDS, you can authenticate without a password when you connect to a DB instance. Instead, you use an authentication token. For more information, see [IAM database authentication for MariaDB, MySQL, and PostgreSQL \(p. 2048\)](#).

IAM database authentication isn't available with the following engines:

- RDS for Oracle
- RDS for SQL Server

Topics

- [IAM database authentication with RDS for MariaDB \(p. 99\)](#)
- [IAM database authentication with RDS for MySQL \(p. 101\)](#)
- [IAM database authentication with RDS for PostgreSQL \(p. 101\)](#)

IAM database authentication with RDS for MySQL

IAM database authentication with RDS for MySQL is available in all Regions for the following versions:

- RDS for MySQL 8.0 (All versions)
- RDS for MySQL 5.7 (All versions)
- RDS for MySQL 5.6 (All versions)

IAM database authentication with RDS for PostgreSQL

IAM database authentication with RDS for PostgreSQL is available in all Regions for the following versions:

- RDS for PostgreSQL 14 (All versions)
- RDS for PostgreSQL 13 (All versions)
- RDS for PostgreSQL 12 (All versions)
- RDS for PostgreSQL 11 (All versions)
- RDS for PostgreSQL 10 (All versions)

Kerberos authentication

By using Kerberos authentication in Amazon RDS, you can support external authentication of database users using Kerberos and Microsoft Active Directory. Using Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. For more information, see [Kerberos authentication \(p. 1999\)](#).

Kerberos authentication isn't available with the following engines:

- RDS for MariaDB

Topics

- [Kerberos authentication with RDS for MySQL \(p. 102\)](#)
- [Kerberos authentication with RDS for Oracle \(p. 103\)](#)
- [Kerberos authentication with RDS for PostgreSQL \(p. 104\)](#)
- [Kerberos authentication with RDS for SQL Server \(p. 106\)](#)

Kerberos authentication with RDS for MySQL

Following are the supported engines and Region availability for Kerberos authentication with RDS for MySQL.

Multi-AZ DB clusters

A Multi-AZ DB cluster deployment in Amazon RDS provides a high availability deployment mode of Amazon RDS with two readable standby DB instances. A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones in the same Region. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower write latency when compared to Multi-AZ DB instance deployments. For more information, see [Multi-AZ DB cluster deployments \(p. 127\)](#).

Multi-AZ DB clusters aren't available with the following engines:

- RDS for MariaDB
- RDS for Oracle
- RDS for SQL Server

Topics

- [Multi-AZ DB clusters with RDS for MySQL \(p. 107\)](#)
- [Multi-AZ DB clusters with RDS for PostgreSQL \(p. 109\)](#)

Multi-AZ DB clusters with RDS for MySQL

Following are the supported engines and Region availability for Multi-AZ DB clusters with RDS for MySQL.

Region	RDS for MySQL 8.0
US East (Ohio)	Version 8.0.28 and higher
US East (N. Virginia)	Version 8.0.28 and higher
US West (N. California)	–
US West (Oregon)	Version 8.0.28 and higher
Africa (Cape Town)	Version 8.0.28 and higher
Asia Pacific (Hong Kong)	Version 8.0.28 and higher

Region	RDS for MySQL 8.0
Asia Pacific (Hyderabad)	–
Asia Pacific (Jakarta)	Version 8.0.28 and higher
Asia Pacific (Mumbai)	Version 8.0.28 and higher
Asia Pacific (Osaka)	Version 8.0.28 and higher
Asia Pacific (Seoul)	Version 8.0.28 and higher
Asia Pacific (Singapore)	Version 8.0.28 and higher
Asia Pacific (Sydney)	Version 8.0.28 and higher
Asia Pacific (Tokyo)	Version 8.0.28 and higher
Canada (Central)	Version 8.0.28 and higher
China (Beijing)	–
China (Ningxia)	–
Europe (Frankfurt)	Version 8.0.28 and higher
Europe (Ireland)	Version 8.0.28 and higher
Europe (London)	Version 8.0.28 and higher
Europe (Milan)	Version 8.0.28 and higher
Europe (Paris)	Version 8.0.28 and higher
Europe (Spain)	–
Europe (Stockholm)	Version 8.0.28 and higher
Europe (Zurich)	–
Middle East (Bahrain)	Version 8.0.28 and higher
Middle East (UAE)	–
South America (São Paulo)	Version 8.0.28 and higher
AWS GovCloud (US-East)	–
AWS GovCloud (US-West)	–

You can also list the supported versions in a Region for the db.r5d.large DB instance class by running the following AWS CLI command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options \
--engine mysql \
--db-instance-class db.r5d.large \
--query '*[]|[?SupportsClusters == `true`].[EngineVersion]' \
--output text
```

For Windows:

```
aws rds describe-orderable-db-instance-options ^
--engine mysql ^
--db-instance-class db.r5d.large ^
--query "[*[]|[?SupportsClusters == `true`].[EngineVersion]]" ^
--output text
```

You can change the DB instance class to show the supported engine versions for it.

Multi-AZ DB clusters with RDS for PostgreSQL

Following are the supported engine version and Region availability for Multi-AZ DB clusters with RDS for PostgreSQL.

Region	RDS for PostgreSQL 14	RDS for PostgreSQL 13
US East (Ohio)	Version 14.5	Version 13.4 and version 13.7
US East (N. Virginia)	Version 14.5	Version 13.4 and version 13.7
US West (N. California)	–	–
US West (Oregon)	Version 14.5	Version 13.4 and version 13.7
Africa (Cape Town)	Version 14.5	Version 13.4 and version 13.7
Asia Pacific (Hong Kong)	Version 14.5	Version 13.4 and version 13.7
Asia Pacific (Hyderabad)	–	–
Asia Pacific (Jakarta)	Version 14.5	Version 13.4 and version 13.7
Asia Pacific (Mumbai)	Version 14.5	Version 13.4 and version 13.7
Asia Pacific (Osaka)	Version 14.5	Version 13.4 and version 13.7
Asia Pacific (Seoul)	Version 14.5	Version 13.4 and version 13.7
Asia Pacific (Singapore)	Version 14.5	Version 13.4 and version 13.7
Asia Pacific (Sydney)	Version 14.5	Version 13.4 and version 13.7
Asia Pacific (Tokyo)	Version 14.5	Version 13.4 and version 13.7
Canada (Central)	Version 14.5	Version 13.4 and version 13.7
China (Beijing)	–	–
China (Ningxia)	–	–
Europe (Frankfurt)	Version 14.5	Version 13.4 and version 13.7
Europe (Ireland)	Version 14.5	Version 13.4 and version 13.7
Europe (London)	Version 14.5	Version 13.4 and version 13.7
Europe (Milan)	Version 14.5	Version 13.4 and version 13.7
Europe (Paris)	Version 14.5	Version 13.4 and version 13.7
Europe (Spain)	–	–

Region	RDS for PostgreSQL 14	RDS for PostgreSQL 13
Europe (Stockholm)	Version 14.5	Version 13.4 and version 13.7
Europe (Zurich)	–	–
Middle East (Bahrain)	Version 14.5	Version 13.4 and version 13.7
Middle East (UAE)	–	–
South America (São Paulo)	Version 14.5	Version 13.4 and version 13.7
AWS GovCloud (US-East)	–	–
AWS GovCloud (US-West)	–	–

You can also list the supported versions in a Region for the db.r5d.large DB instance class by running the following AWS CLI command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options \
--engine postgres \
--db-instance-class db.r5d.large \
--query '*[]|[?SupportsClusters == `true`].[EngineVersion]' \
--output text
```

For Windows:

```
aws rds describe-orderable-db-instance-options ^
--engine postgres ^
--db-instance-class db.r5d.large ^
--query "*[]|[?SupportsClusters == `true`].[EngineVersion]" ^
--output text
```

You can change the DB instance class to show the supported engine versions for it.

Performance Insights

Performance Insights in Amazon RDS expands on existing Amazon RDS monitoring features to illustrate and help you analyze your database performance. With the Performance Insights dashboard, you can visualize the database load on your Amazon RDS DB instance. You can also filter the load by waits, SQL statements, hosts, or users. For more information, see [Monitoring DB load with Performance Insights on Amazon RDS \(p. 543\)](#).

Performance Insights is available for all RDS DB engines and all versions.

Performance Insights is available in all AWS Regions except the following:

- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

RDS Custom

Amazon RDS Custom automates database administration tasks and operations. By using RDS Custom, as a database administrator you can access and customize your database environment and operating

system. With RDS Custom, you can customize to meet the requirements of legacy, custom, and packaged applications. For more information, see [Working with Amazon RDS Custom \(p. 755\)](#).

RDS Custom isn't available with the following engines:

- RDS for MariaDB
- RDS for MySQL
- RDS for PostgreSQL

Topics

- [RDS Custom with RDS for Oracle \(p. 111\)](#)
- [RDS Custom with RDS for SQL Server \(p. 113\)](#)

RDS Custom with RDS for Oracle

Engine-native features

Amazon RDS database engines also support many of the most common engine-native features and functionality. These features are different than the Amazon RDS-native features listed on this page. Some engine-native features might have limited support or restricted privileges.

For more information on engine-native features, see:

- [MariaDB feature support on Amazon RDS \(p. 975\)](#)
- [MySQL feature support on Amazon RDS \(p. 1312\)](#)
- [RDS for Oracle features \(p. 1467\)](#)
- [Working with PostgreSQL features supported by Amazon RDS for PostgreSQL \(p. 1905\)](#)
- [Microsoft SQL Server features on Amazon RDS \(p. 1068\)](#)

Multi-AZ deployments for high availability

Multi-AZ deployments can have one standby or two standby DB instances. When the deployment has one standby DB instance, it's called a *Multi-AZ DB instance deployment*. A Multi-AZ DB instance deployment has one standby DB instance that provides failover support, but doesn't serve read traffic. When the deployment has two standby DB instances, it's called a *Multi-AZ DB cluster deployment*. A Multi-AZ DB cluster deployment has standby DB instances that provide failover support and can also serve read traffic.

You can use the AWS Management Console to determine whether a Multi-AZ deployment is a Multi-AZ DB instance deployment or a Multi-AZ DB cluster deployment. In the navigation pane, choose **Databases**, and then choose a **DB identifier**.

- A Multi-AZ DB instance deployment has the following characteristics:
 - There is only one row for the DB instance.
 - The value of **Role** is **Instance or Primary**.
 - The value of **Multi-AZ** is **Yes**.
- A Multi-AZ DB cluster deployment has the following characteristics:
 - There is a cluster-level row with three DB instance rows under it.
 - For the cluster-level row, the value of **Role** is **Multi-AZ DB cluster**.
 - For each instance-level row, the value of **Role** is **Writer instance** or **Reader instance**.
 - For each instance-level row, the value of **Multi-AZ** is **3 Zones**.

Topics

- [Multi-AZ DB instance deployments \(p. 122\)](#)
- [Multi-AZ DB cluster deployments \(p. 127\)](#)

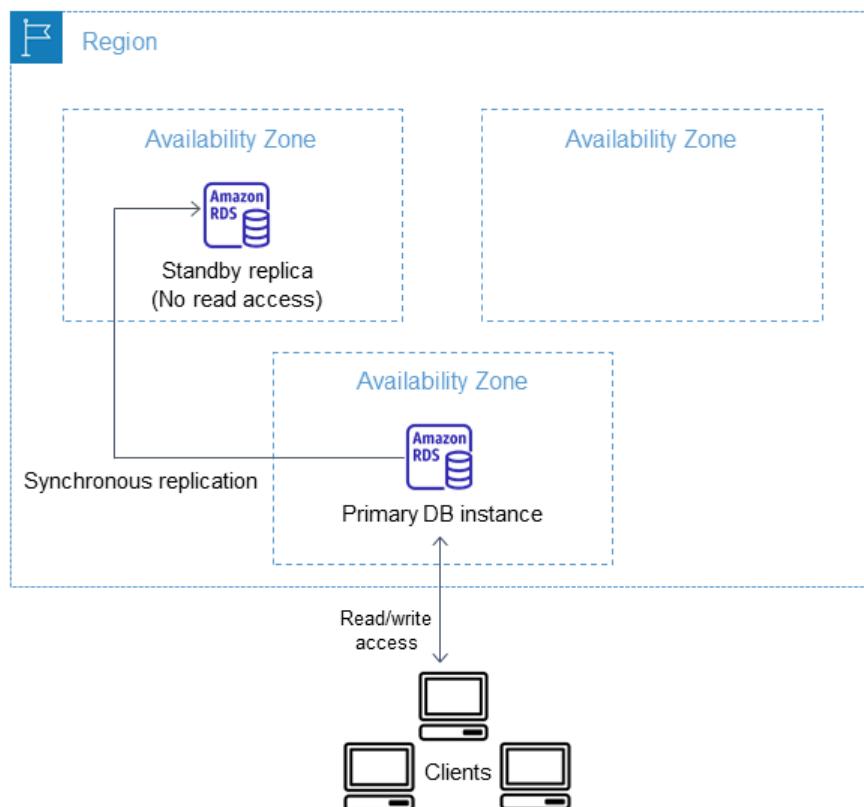

Multi-AZ DB instance deployments

Amazon RDS provides high availability and failover support for DB instances using Multi-AZ deployments with a single standby DB instance. This type of deployment is called a *Multi-AZ DB instance deployment*. Amazon RDS uses several different technologies to provide this failover support. Multi-AZ deployments for MariaDB, MySQL, Oracle, and PostgreSQL DB instances use the Amazon failover technology. Microsoft SQL Server DB instances use SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). For information on SQL Server version support for Multi-AZ, see [Multi-AZ deployments for Amazon RDS for Microsoft SQL Server \(p. 1129\)](#).

In a Multi-AZ DB instance deployment, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different Availability Zone. The primary DB instance is synchronously replicated across Availability Zones to a standby replica to provide data redundancy and minimize latency spikes during system backups. Running a DB instance with high availability can enhance availability during planned system maintenance. It can also help protect your databases against DB instance failure and Availability Zone disruption. For more information on Availability Zones, see [Regions, Availability Zones, and Local Zones \(p. 72\)](#).

Note

The high availability option isn't a scaling solution for read-only scenarios. You can't use a standby replica to serve read traffic. To serve read-only traffic, use a Multi-AZ DB cluster or a read replica instead. For more information about Multi-AZ DB clusters, see [Multi-AZ DB cluster deployments \(p. 127\)](#). For more information about read replicas, see [Working with read replicas \(p. 370\)](#).

Using the RDS console, you can create a Multi-AZ DB instance deployment by simply specifying Multi-AZ when creating a DB instance. You can use the console to convert existing DB instances to Multi-AZ DB instance deployments by modifying the DB instance and specifying the Multi-AZ option. You can also specify a Multi-AZ DB instance deployment with the AWS CLI or Amazon RDS API. Use the [create-](#)

[db-instance](#) or [modify-db-instance](#) CLI command, or the [CreateDBInstance](#) or [ModifyDBInstance](#) API operation.

The RDS console shows the Availability Zone of the standby replica (called the secondary AZ). You can also use the [describe-db-instances](#) CLI command or the [DescribeDBInstances](#) API operation to find the secondary AZ.

DB instances using Multi-AZ DB instance deployments can have increased write and commit latency compared to a Single-AZ deployment. This can happen because of the synchronous data replication that occurs. You might have a change in latency if your deployment fails over to the standby replica, although AWS is engineered with low-latency network connectivity between Availability Zones. For production workloads, we recommend that you use Provisioned IOPS (input/output operations per second) for fast, consistent performance. For more information about DB instance classes, see [DB instance classes \(p. 10\)](#).

Modifying a DB instance to be a Multi-AZ DB instance deployment

If you have a DB instance in a Single-AZ deployment and modify it to a Multi-AZ DB instance deployment (for engines other than Amazon Aurora), Amazon RDS performs several actions:

1. Takes a snapshot of the primary DB instance's Amazon Elastic Block Store (EBS) volumes.
2. Creates new volumes for the standby replica from the snapshot. These volumes initialize in the background, and maximum volume performance is achieved after the data is fully initialized.
3. Turns on synchronous block-level replication between the volumes of the primary and standby replicas.

Important

Using a snapshot to create the standby instance avoids downtime when you convert from Single-AZ to Multi-AZ, but you can experience a performance impact during and after converting to Multi-AZ. This impact can be significant for workloads that are sensitive to write latency.

While this capability lets large volumes be restored from snapshots quickly, it can cause a significant increase in the latency of I/O operations because of the synchronous replication. This latency can impact your database performance. We highly recommend as a best practice not to perform Multi-AZ conversion on a production DB instance.

To avoid the performance impact on the DB instance currently serving the sensitive workload, create a read replica and enable backups on the read replica. Convert the read replica to Multi-AZ, and run queries that load the data into the read replica's volumes (on both AZs). Then promote the read replica to be the primary DB instance. For more information, see [Working with read replicas \(p. 370\)](#).

For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#). After the modification is complete, Amazon RDS triggers an event (RDS-EVENT-0025) that indicates the process is complete. You can monitor Amazon RDS events. For more information about events, see [Working with Amazon RDS event notification \(p. 650\)](#).

Failover process for Amazon RDS

If a planned or unplanned outage of your DB instance results from an infrastructure defect, Amazon RDS automatically switches to a standby replica in another Availability Zone if you have turned on Multi-AZ. The time that it takes for the failover to complete depends on the database activity and other conditions at the time the primary DB instance became unavailable. Failover times are typically 60–120 seconds. However, large transactions or a lengthy recovery process can increase failover time. When the failover is complete, it can take additional time for the RDS console to reflect the new Availability Zone.

Note

You can force a failover manually when you reboot a DB instance. For more information, see [Rebooting a DB instance \(p. 366\)](#).

Amazon RDS handles failovers automatically so you can resume database operations as quickly as possible without administrative intervention. The primary DB instance switches over automatically to the standby replica if any of the conditions described in the following table occurs. You can view these failover reasons in the event log.

Failover reason	Description
The operating system underlying the RDS database instance is being patched in an offline operation.	<p>A failover was triggered during the maintenance window for an OS patch or a security update.</p> <p>For more information, see Maintaining a DB instance (p. 350).</p>
The primary host of the RDS Multi-AZ instance is unhealthy.	The Multi-AZ DB instance deployment detected an impaired primary DB instance and failed over.
The primary host of the RDS Multi-AZ instance is unreachable due to loss of network connectivity.	RDS monitoring detected a network reachability failure to the primary DB instance and triggered a failover.
The RDS instance was modified by customer.	<p>An RDS DB instance modification triggered a failover.</p> <p>For more information, see Modifying an Amazon RDS DB instance (p. 327).</p>
The RDS Multi-AZ primary instance is busy and unresponsive.	<p>The primary DB instance is unresponsive. We recommend that you do the following:</p> <ul style="list-style-type: none"> • Examine the event and CloudWatch logs for excessive CPU, memory, or swap space usage. For more information, see Working with Amazon RDS event notification (p. 650) and Creating a rule that triggers on an Amazon RDS event (p. 664). • Evaluate your workload to determine whether you're using the appropriate DB instance class. For more information, see DB instance classes (p. 10). • Use Enhanced Monitoring for real-time operating system metrics. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 600). • Use Performance Insights to help analyze any issues that affect your DB instance's performance. For more information, see Monitoring DB load with Performance Insights on Amazon RDS (p. 543). <p>For more information on these recommendations, see Overview of monitoring metrics in Amazon RDS (p. 511) and Best practices for Amazon RDS (p. 216).</p>

Failover reason	Description
The storage volume underlying the primary host of the RDS Multi-AZ instance experienced a failure.	The Multi-AZ DB instance deployment detected a storage issue on the primary DB instance and failed over.
The user requested a failover of the DB instance.	<p>You rebooted the DB instance and chose Reboot with failover.</p> <p>For more information, see Rebooting a DB instance (p. 366).</p>

To determine if your Multi-AZ DB instance has failed over, you can do the following:

- Set up DB event subscriptions to notify you by email or SMS that a failover has been initiated. For more information about events, see [Working with Amazon RDS event notification \(p. 650\)](#).
- View your DB events by using the RDS console or API operations.
- View the current state of your Multi-AZ DB instance deployment by using the RDS console or API operations.

For information on how you can respond to failovers, reduce recovery time, and other best practices for Amazon RDS, see [Best practices for Amazon RDS \(p. 216\)](#).

Setting the JVM TTL for DNS name lookups

The failover mechanism automatically changes the Domain Name System (DNS) record of the DB instance to point to the standby DB instance. As a result, you need to re-establish any existing connections to your DB instance. In a Java virtual machine (JVM) environment, due to how the Java DNS caching mechanism works, you might need to reconfigure JVM settings.

The JVM caches DNS name lookups. When the JVM resolves a host name to an IP address, it caches the IP address for a specified period of time, known as the *time-to-live* (TTL).

Because AWS resources use DNS name entries that occasionally change, we recommend that you configure your JVM with a TTL value of no more than 60 seconds. Doing this makes sure that when a resource's IP address changes, your application can receive and use the resource's new IP address by querying the DNS.

On some Java configurations, the JVM default TTL is set so that it never refreshes DNS entries until the JVM is restarted. Thus, if the IP address for an AWS resource changes while your application is still running, it can't use that resource until you manually restart the JVM and the cached IP information is refreshed. In this case, it's crucial to set the JVM's TTL so that it periodically refreshes its cached IP information.

Note

The default TTL can vary according to the version of your JVM and whether a security manager is installed. Many JVMs provide a default TTL less than 60 seconds. If you're using such a JVM and not using a security manager, you can ignore the rest of this topic. For more information on security managers in Oracle, see [The security manager](#) in the Oracle documentation.

To modify the JVM's TTL, set the `networkaddress.cache.ttl` property value. Use one of the following methods, depending on your needs:

- To set the property value globally for all applications that use the JVM, set `networkaddress.cache.ttl` in the `$JAVA_HOME/jre/lib/security/java.security` file.

```
networkaddress.cache.ttl=60
```

- To set the property locally for your application only, set `networkaddress.cache.ttl` in your application's initialization code before any network connections are established.

```
java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
```

Multi-AZ DB cluster deployments

A *Multi-AZ DB cluster deployment* is a high availability deployment mode of Amazon RDS with two readable standby DB instances. A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones in the same AWS Region. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower write latency when compared to Multi-AZ DB instance deployments.

Topics

- [Failover process for Multi-AZ DB clusters \(p. 134\)](#)
- [Limitations for Multi-AZ DB clusters \(p. 136\)](#)

Important

Multi-AZ DB clusters aren't the same as Aurora DB clusters. For information about Aurora DB clusters, see the [Amazon Aurora User Guide](#).

Region and version availability

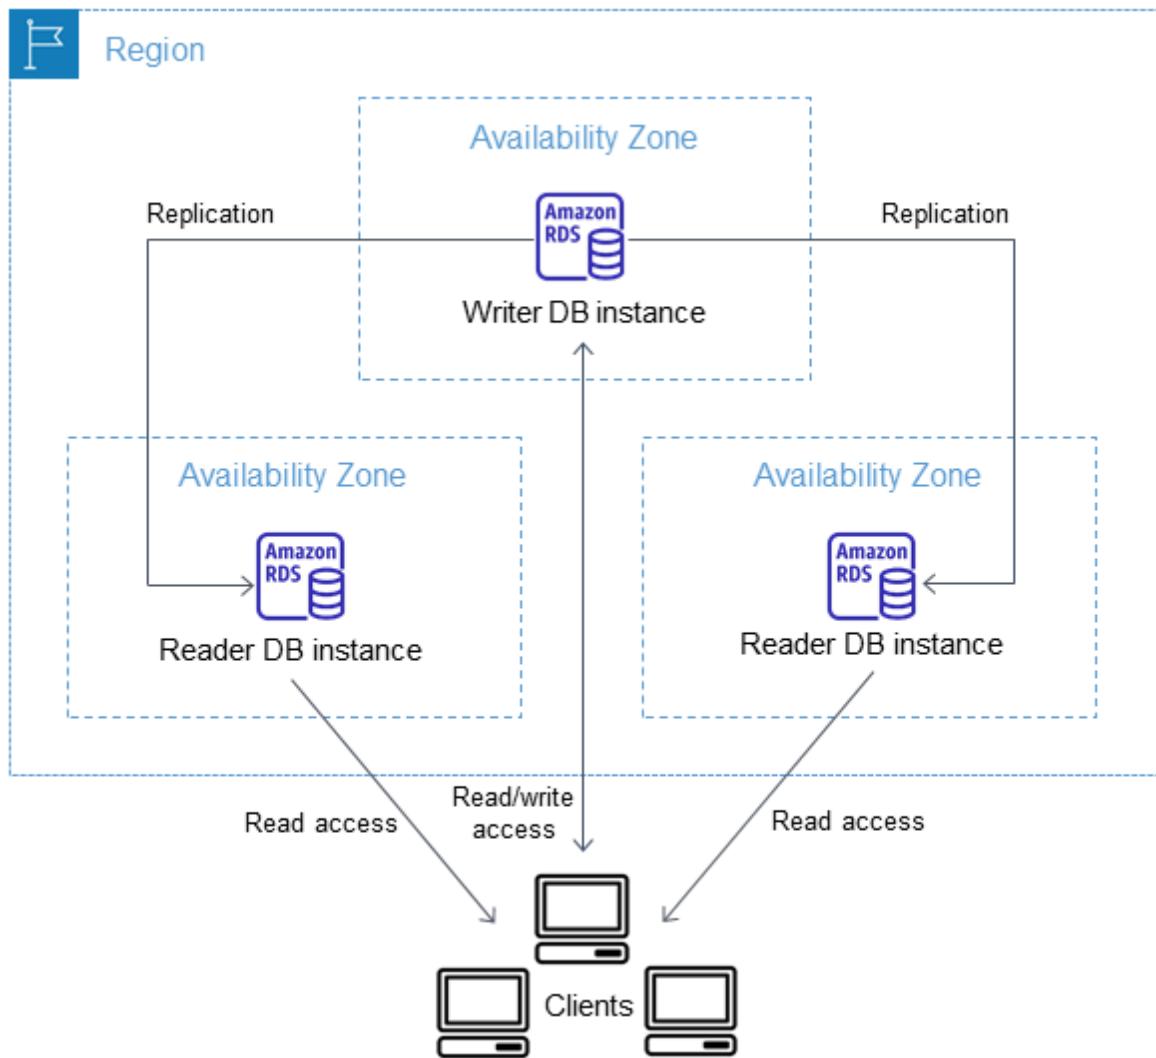

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Multi-AZ DB clusters, see [Multi-AZ DB clusters \(p. 107\)](#).

Overview of Multi-AZ DB clusters

With a Multi-AZ DB cluster, Amazon RDS replicates data from the writer DB instance to both of the reader DB instances using the DB engine's native replication capabilities. When a change is made on the writer DB instance, it's sent to each reader DB instance. Acknowledgment from at least one reader DB instance is required for a change to be committed.

Reader DB instances act as automatic failover targets and also serve read traffic to increase application read throughput. If an outage occurs on your writer DB instance, RDS manages failover to one of the reader DB instances. RDS does this based on which reader DB instance has the most recent change record.

The following diagram shows a Multi-AZ DB cluster.

Multi-AZ DB clusters typically have lower write latency when compared to Multi-AZ DB instance deployments. They also allow read-only workloads to run on reader DB instances. The RDS console shows the Availability Zone of the writer DB instance and the Availability Zones of the reader DB instances. You can also use the [describe-db-clusters](#) CLI command or the [DescribeDBClusters](#) API operation to find this information.

Creating and managing a Multi-AZ DB cluster

You can create a Multi-AZ DB cluster directly or by restoring from a snapshot. For instructions, see these topics:

- [Creating a Multi-AZ DB cluster \(p. 252\)](#)
- [Restoring from a snapshot to a Multi-AZ DB cluster \(p. 456\)](#)

You can modify, reboot, or delete a Multi-AZ DB by following the instructions in these topics:

- [Modifying a Multi-AZ DB cluster \(p. 341\)](#)
- [Rebooting Multi-AZ DB clusters and reader DB instances \(p. 368\)](#)

- [Deleting a Multi-AZ DB cluster \(p. 424\)](#)

You can create a snapshot of a Multi-AZ DB cluster by following the instructions in [Creating a Multi-AZ DB cluster snapshot \(p. 450\)](#).

You can restore a Multi-AZ DB cluster to a point in time by following the instructions in [Restoring a Multi-AZ DB cluster to a specified time \(p. 502\)](#).

Managing connections for Multi-AZ DB clusters

A Multi-AZ DB cluster has three DB instances instead of a single DB instance. Each connection is handled by a specific DB instance. When you connect to a Multi-AZ DB cluster, the host name and port that you specify point to a fully qualified domain name called an *endpoint*. The Multi-AZ DB cluster uses the endpoint mechanism to abstract these connections. Thus, you don't have to hardcode all the host names or write your own logic for rerouting connections when some DB instances aren't available.

The writer endpoint connects to the writer DB instance of the DB cluster, which supports both read and write operations. The reader endpoint connects to either of the two reader DB instances, which support only read operations.

Using endpoints, you can map each connection to the appropriate DB instance or group of DB instances based on your use case. For example, to perform DDL and DML statements, you can connect to whichever DB instance is the writer DB instance. To perform queries, you can connect to the reader endpoint, with the Multi-AZ DB cluster automatically managing connections among the reader DB instances. For diagnosis or tuning, you can connect to a specific DB instance endpoint to examine details about a specific DB instance.

For information about connecting to a DB instance, see [Connecting to an Amazon RDS DB instance \(p. 267\)](#).

Topics

- [Types of Multi-AZ DB cluster endpoints \(p. 129\)](#)
- [Viewing the endpoints for a Multi-AZ DB cluster \(p. 130\)](#)
- [Using the cluster endpoint \(p. 130\)](#)
- [Using the reader endpoint \(p. 131\)](#)
- [Using the instance endpoints \(p. 131\)](#)
- [How Multi-AZ DB endpoints work with high availability \(p. 131\)](#)

Types of Multi-AZ DB cluster endpoints

An endpoint is represented by a unique identifier that contains a host address. The following types of endpoints are available from a Multi-AZ DB cluster:

Cluster endpoint

A *cluster endpoint* (or *writer endpoint*) for a Multi-AZ DB cluster connects to the current writer DB instance for that DB cluster. This endpoint is the only one that can perform write operations such as DDL and DML statements. This endpoint can also perform read operations.

Each Multi-AZ DB cluster has one cluster endpoint and one writer DB instance.

You use the cluster endpoint for all write operations on the DB cluster, including inserts, updates, deletes, and DDL changes. You can also use the cluster endpoint for read operations, such as queries.

If the current writer DB instance of a DB cluster fails, the Multi-AZ DB cluster automatically fails over to a new writer DB instance. During a failover, the DB cluster continues to serve connection requests to the cluster endpoint from the new writer DB instance, with minimal interruption of service.

The following example illustrates a cluster endpoint for a Multi-AZ DB cluster.

`mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com`

Reader endpoint

A *reader endpoint* for a Multi-AZ DB cluster provides support for read-only connections to the DB cluster. Use the reader endpoint for read operations, such as SELECT queries. By processing those statements on the reader DB instances, this endpoint reduces the overhead on the writer DB instance. It also helps the cluster to scale the capacity to handle simultaneous SELECT queries. Each Multi-AZ DB cluster has one reader endpoint.

The reader endpoint sends each connection request to one of the reader DB instances. When you use the reader endpoint for a session, you can only perform read-only statements such as SELECT in that session.

The following example illustrates a reader endpoint for a Multi-AZ DB cluster. The read-only intent of a reader endpoint is denoted by the `-ro` within the cluster endpoint name.

`mydbcluster.cluster-ro-123456789012.us-east-1.rds.amazonaws.com`

Instance endpoint

An *instance endpoint* connects to a specific DB instance within a Multi-AZ DB cluster. Each DB instance in a DB cluster has its own unique instance endpoint. So there is one instance endpoint for the current writer DB instance of the DB cluster, and there is one instance endpoint for each of the reader DB instances in the DB cluster.

The instance endpoint provides direct control over connections to the DB cluster. This control can help you address scenarios where using the cluster endpoint or reader endpoint might not be appropriate. For example, your client application might require more fine-grained load balancing based on workload type. In this case, you can configure multiple clients to connect to different reader DB instances in a DB cluster to distribute read workloads.

The following example illustrates an instance endpoint for a DB instance in a Multi-AZ DB cluster.

`mydbinstance.123456789012.us-east-1.rds.amazonaws.com`

Viewing the endpoints for a Multi-AZ DB cluster

In the AWS Management Console, you see the cluster endpoint and the reader endpoint on the details page for each Multi-AZ DB cluster. You see the instance endpoint in the details page for each DB instance.

With the AWS CLI, you see the writer and reader endpoints in the output of the `describe-db-clusters` command. For example, the following command shows the endpoint attributes for all clusters in your current AWS Region.

```
aws rds describe-db-cluster-endpoints
```

With the Amazon RDS API, you retrieve the endpoints by calling the `DescribeDBClusterEndpoints` action. The output also shows Amazon Aurora DB cluster endpoints, if any exist.

Using the cluster endpoint

Each Multi-AZ DB cluster has a single built-in cluster endpoint, whose name and other attributes are managed by Amazon RDS. You can't create, delete, or modify this kind of endpoint.

You use the cluster endpoint when you administer your DB cluster, perform extract, transform, load (ETL) operations, or develop and test applications. The cluster endpoint connects to the writer DB instance of

the cluster. The writer DB instance is the only DB instance where you can create tables and indexes, run INSERT statements, and perform other DDL and DML operations.

The physical IP address pointed to by the cluster endpoint changes when the failover mechanism promotes a new DB instance to be the writer DB instance for the cluster. If you use any form of connection pooling or other multiplexing, be prepared to flush or reduce the time-to-live for any cached DNS information. Doing so ensures that you don't try to establish a read/write connection to a DB instance that became unavailable or is now read-only after a failover.

Using the reader endpoint

You use the reader endpoint for read-only connections to your Multi-AZ DB cluster. This endpoint helps your DB cluster handle a query-intensive workload. The reader endpoint is the endpoint that you supply to applications that do reporting or other read-only operations on the cluster. The reader endpoint sends connections to available reader DB instances in a Multi-AZ DB cluster.

Each Multi-AZ cluster has a single built-in reader endpoint, whose name and other attributes are managed by Amazon RDS. You can't create, delete, or modify this kind of endpoint.

Using the instance endpoints

Each DB instance in a Multi-AZ DB cluster has its own built-in instance endpoint, whose name and other attributes are managed by Amazon RDS. You can't create, delete, or modify this kind of endpoint. With a Multi-AZ DB cluster, you typically use the writer and reader endpoints more often than the instance endpoints.

In day-to-day operations, the main way that you use instance endpoints is to diagnose capacity or performance issues that affect one specific DB instance in a Multi-AZ DB cluster. While connected to a specific DB instance, you can examine its status variables, metrics, and so on. Doing this can help you determine what's happening for that DB instance that's different from what's happening for other DB instances in the cluster.

How Multi-AZ DB endpoints work with high availability

For Multi-AZ DB clusters where high availability is important, use the writer endpoint for read/write or general-purpose connections and the reader endpoint for read-only connections. The writer and reader endpoints manage DB instance failover better than instance endpoints do. Unlike the instance endpoints, the writer and reader endpoints automatically change which DB instance they connect to if a DB instance in your cluster becomes unavailable.

If the writer DB instance of a DB cluster fails, Amazon RDS automatically fails over to a new writer DB instance. It does so by promoting a reader DB instance to a new writer DB instance. If a failover occurs, you can use the writer endpoint to reconnect to the newly promoted writer DB instance. Or you can use the reader endpoint to reconnect to one of the reader DB instances in the DB cluster. During a failover, the reader endpoint might direct connections to the new writer DB instance of a DB cluster for a short time after a reader DB instance is promoted to the new writer DB instance. If you design your own application logic to manage instance endpoint connections, you can manually or programmatically discover the resulting set of available DB instances in the DB cluster.

Managing a Multi-AZ DB cluster with the AWS Management Console

You can manage a Multi-AZ DB cluster with the console.

To manage a Multi-AZ DB cluster with the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Databases**, and then choose the Multi-AZ DB cluster that you want to manage.

The following image shows a Multi-AZ DB cluster in the console.

DB identifier	Role	Engine	Region & AZ	Size
my-multi-az-cluster	Multi-AZ DB cluster	PostgreSQL	us-west-2	3 instances
my-multi-az-cluster-instance-1	Writer instance	PostgreSQL	us-west-2a	db.m6gd.xlarge
my-multi-az-cluster-instance-2	Reader instance	PostgreSQL	us-west-2c	db.m6gd.xlarge
my-multi-az-cluster-instance-3	Reader instance	PostgreSQL	us-west-2b	db.m6gd.xlarge

The available actions in the **Actions** menu depend on whether the Multi-AZ DB cluster is selected or a DB instance in the cluster is selected.

Choose the Multi-AZ DB cluster to view the cluster details and perform actions at the cluster level.

Choose a DB instance in a Multi-AZ DB cluster to view the DB instance details and perform actions at the DB instance level.

Working with parameter groups for Multi-AZ DB clusters

In a Multi-AZ DB cluster, a *DB cluster parameter group* acts as a container for engine configuration values that are applied to every DB instance in the Multi-AZ DB cluster.

In a Multi-AZ DB cluster, a *DB parameter group* is set to the default DB parameter group for the DB engine and DB engine version. The settings in the DB cluster parameter group are used for all of the DB instances in the cluster.

For information about parameter groups, see [Working with parameter groups \(p. 289\)](#).

Replica lag and Multi-AZ DB clusters

Replica lag is the difference in time between the latest transaction on the writer DB instance and the latest applied transaction on a reader DB instance. The Amazon CloudWatch metric `ReplicaLag` represents this time difference. For more information about CloudWatch metrics, see [Monitoring Amazon RDS metrics with Amazon CloudWatch \(p. 528\)](#).

Although Multi-AZ DB clusters allow for high write performance, replica lag can still occur due to the nature of engine-based replication. Because any failover must first resolve the replica lag before it promotes a new writer DB instance, monitoring and managing this replica lag is a consideration.

For RDS for MySQL Multi-AZ DB clusters, failover time depends on replica lag of both remaining reader DB instances. Both the reader DB instances must apply unapplied transactions before one of them is promoted to the new writer DB instance.

For RDS for PostgreSQL Multi-AZ DB clusters, failover time depends on the lowest replica lag of the two remaining reader DB instances. The reader DB instance with the lowest replica lag must apply unapplied transactions before it is promoted to the new writer DB instance.

For a tutorial that shows you how to create a CloudWatch alarm when replica lag exceeds a set amount of time, see [Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag \(p. 536\)](#).

Common causes of replica lag

In general, replica lag occurs when the write workload is too high for the reader DB instances to apply the transactions efficiently. Various workloads can incur temporary or continuous replica lag. Some examples of common causes are the following:

- High write concurrency or heavy batch updating on the writer DB instance, causing the apply process on the reader DB instances to fall behind.
- Heavy read workload that is using resources on one or more reader DB instances. Running slow or large queries can affect the apply process and can cause replica lag.
- Transactions that modify large amounts of data or DDL statements can sometimes cause a temporary increase in replica lag because the database must preserve commit order.

Mitigating replica lag

For Multi-AZ DB clusters for RDS for MySQL and RDS for PostgreSQL, you can mitigate replica lag by reducing the load on your writer DB instance. You can also use flow control to reduce replica lag. *Flow control* works by throttling writes on the writer DB instance, which ensures that replica lag doesn't continue to grow unbounded. Write throttling is accomplished by adding a delay into the end of a transaction, which decreases the write throughput on the writer DB instance. Although flow control doesn't guarantee lag elimination, it can help reduce overall lag in many workloads. The following sections provide information about using flow control with RDS for MySQL and RDS for PostgreSQL.

Mitigating replica lag with flow control for RDS for MySQL

When you are using RDS for MySQL Multi-AZ DB clusters, flow control is turned on by default using the dynamic parameter `rpl_semi_sync_master_target_apply_lag`. This parameter specifies the upper limit that you want for replica lag. As replica lag approaches this configured limit, flow control throttles the write transactions on the writer DB Instance to try to contain the replica lag below the specified value. In some cases, replica lag can exceed the specified limit. By default, this parameter is set to 120 seconds. To turn off flow control, set this parameter to its maximum value of 86400 seconds (one day).

To view the current delay injected by flow control, show the parameter `Rpl_semi_sync_master_flow_control_current_delay` by running the following query.

```
SHOW GLOBAL STATUS like '%flow_control%';
```

Your output looks similar to the following.

Variable_name	Value
Rpl_semi_sync_master_flow_control_current_delay	2010

1 row in set (0.00 sec)

Note

The delay is shown in microseconds.

When you have Performance Insights turned on for an RDS for MySQL Multi-AZ DB cluster, you can monitor the wait event corresponding to a SQL statement indicating that the queries were delayed by a flow control. When a delay was introduced by a flow control, you can view the wait event / `wait/synch/cond/semisync/semi_sync_flow_control_delay_cond` corresponding to the SQL statement on the Performance Insights dashboard. To view these metrics, make sure that the Performance Schema is turned on. For information about Performance Insights, see [Monitoring DB load with Performance Insights on Amazon RDS \(p. 543\)](#).

Mitigating replica lag with flow control for RDS for PostgreSQL

When you are using RDS for PostgreSQL Multi-AZ DB clusters, flow control is deployed as an extension. It turns on a background worker for all DB instances in the DB cluster. By default, the background workers on the reader DB instances communicate the current replica lag with the background worker on the writer DB instance. If the lag exceeds two minutes on any reader DB instance, the background worker on the writer DB instance adds a delay at the end of a transaction. To control the lag threshold, use the parameter `flow_control.target_standby_apply_lag`.

When a flow control throttles a PostgreSQL process, the Extension wait event in `pg_stat_activity` and Performance Insights indicates that. The function `get_flow_control_stats` displays details about how much delay is currently being added.

Flow control can benefit most online transaction processing (OLTP) workloads that have short but highly concurrent transactions. If the lag is caused by long-running transactions, such as batch operations, flow control doesn't provide as strong a benefit.

You can turn off flow control by removing the extension from the `preload_shared_libraries` and rebooting your DB instance.

Failover process for Multi-AZ DB clusters

If there is a planned or unplanned outage of your writer DB instance in a Multi-AZ DB cluster, Amazon RDS automatically fails over to a reader DB instance in different Availability Zone. The time it takes for

the failover to complete depends on the database activity and other conditions when the writer DB instance became unavailable. Failover times are typically under 35 seconds. Failover completes when both reader DB instances have applied outstanding transactions from the failed writer. When the failover is complete, it can take additional time for the RDS console to reflect the new Availability Zone.

Topics

- [Automatic failovers \(p. 135\)](#)
- [Manually failing over a Multi-AZ DB cluster \(p. 135\)](#)
- [Determining whether a Multi-AZ DB cluster has failed over \(p. 135\)](#)
- [Setting the JVM TTL for DNS name lookups \(p. 136\)](#)

Automatic failovers

Amazon RDS handles failovers automatically so you can resume database operations as quickly as possible without administrative intervention. To fail over, the writer DB instance switches automatically to a reader DB instance.

Manually failing over a Multi-AZ DB cluster

You can fail over a Multi-AZ DB cluster manually using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To fail over a Multi-AZ DB cluster manually

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Multi-AZ DB cluster that you want to fail over.
4. For **Actions**, choose **Failover**.

The **Failover DB Cluster** page appears.

5. Choose **Failover** to confirm the manual failover.

AWS CLI

To fail over a Multi-AZ DB cluster manually, use the AWS CLI command [failover-db-cluster](#).

Example

```
aws rds failover-db-cluster --db-cluster-identifier mymultiazdbcluster
```

RDS API

To fail over a Multi-AZ DB cluster manually, call the Amazon RDS API [FailoverDBCluster](#) and specify the `DBClusterIdentifier`.

Determining whether a Multi-AZ DB cluster has failed over

To determine if your Multi-AZ DB cluster has failed over, you can do the following:

- Set up DB event subscriptions to notify you by email or SMS that a failover has been initiated. For more information about events, see [Working with Amazon RDS event notification \(p. 650\)](#).

- View your DB events by using the Amazon RDS console or API operations.
- View the current state of your Multi-AZ DB cluster by using the Amazon RDS console, the AWS CLI, and the RDS API.

For information on how you can respond to failovers, reduce recovery time, and other best practices for Amazon RDS, see [Best practices for Amazon RDS \(p. 216\)](#).

Setting the JVM TTL for DNS name lookups

The failover mechanism automatically changes the Domain Name System (DNS) record of the DB instance to point to the reader DB instance. As a result, you need to re-establish any existing connections to your DB instance. In a Java virtual machine (JVM) environment, due to how the Java DNS caching mechanism works, you might need to reconfigure JVM settings.

The JVM caches DNS name lookups. When the JVM resolves a host name to an IP address, it caches the IP address for a specified period of time, known as the *time-to-live* (TTL).

Because AWS resources use DNS name entries that occasionally change, we recommend that you configure your JVM with a TTL value of no more than 60 seconds. Doing this makes sure that when a resource's IP address changes, your application can receive and use the resource's new IP address by requerying the DNS.

On some Java configurations, the JVM default TTL is set so that it never refreshes DNS entries until the JVM is restarted. Thus, if the IP address for an AWS resource changes while your application is still running, it can't use that resource until you manually restart the JVM and the cached IP information is refreshed. In this case, it's crucial to set the JVM's TTL so that it periodically refreshes its cached IP information.

Note

The default TTL can vary according to the version of your JVM and whether a security manager is installed. Many JVMs provide a default TTL less than 60 seconds. If you're using such a JVM and not using a security manager, you can ignore the rest of this topic. For more information on security managers in Oracle, see [The security manager](#) in the Oracle documentation.

To modify the JVM's TTL, set the `networkaddress.cache.ttl` property value. Use one of the following methods, depending on your needs:

- To set the property value globally for all applications that use the JVM, set `networkaddress.cache.ttl` in the `$JAVA_HOME/jre/lib/security/java.security` file.

```
networkaddress.cache.ttl=60
```

- To set the property locally for your application only, set `networkaddress.cache.ttl` in your application's initialization code before any network connections are established.

```
java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
```

Limitations for Multi-AZ DB clusters

The following limitations apply to Multi-AZ DB clusters:

- Multi-AZ DB clusters only support Provisioned IOPS storage.

- You can't change a single-AZ DB instance deployment or Multi-AZ DB instance deployment into a Multi-AZ DB cluster. As an alternative, you can restore a snapshot of a single-AZ DB instance deployment or Multi-AZ DB instance deployment to a Multi-AZ DB cluster.
- You can't restore a Multi-AZ DB cluster snapshot to a Multi-AZ DB instance deployment or single-AZ deployment.
- Multi-AZ DB clusters don't support modifications at the DB instance level because all modifications are done at the DB cluster level.
- Multi-AZ DB clusters don't support the following features:
 - Amazon RDS Proxy
 - Support for IPv6 connections (dual-stack mode)
 - Exporting Multi-AZ DB cluster snapshot data to an Amazon S3 bucket
 - IAM DB authentication
 - Kerberos authentication
 - Modifying the port

As an alternative, you can restore a Multi-AZ DB cluster to a point in time and specify a different port.

- Option groups
- Read replicas
- Reserved DB instances
- Restoring a Multi-AZ DB cluster snapshot from an Amazon S3 bucket
- Storage autoscaling by setting the maximum allocated storage

As an alternative, you can scale storage manually.

- Stopping and starting the DB cluster
- Copying a snapshot of a Multi-AZ DB cluster
- Encrypting an unencrypted Multi-AZ DB cluster
- RDS for MySQL Multi-AZ DB clusters don't support replication to an external target database.
- RDS for MySQL Multi-AZ DB clusters support only the following system stored procedures:
 - `mysql.rds_rotate_general_log`
 - `mysql.rds_rotate_slow_log`
 - `mysql.rds_show_configuration`

RDS for MySQL Multi-AZ DB clusters don't support other system stored procedures. For information about these procedures, see [MySQL on Amazon RDS SQL reference \(p. 1439\)](#).

- RDS for PostgreSQL Multi-AZ DB clusters don't support the following PostgreSQL extensions: `aws_s3`, `pg_transport`, and `pglogical`.
- RDS for PostgreSQL Multi-AZ DB clusters don't support using a custom DNS server for outbound network access.
- RDS for PostgreSQL Multi-AZ DB clusters don't support logical replication.

DB instance billing for Amazon RDS

Amazon RDS instances are billed based on the following components:

- DB instance hours (per hour) – Based on the DB instance class of the DB instance (for example, db.t2.small or db.m4.large). Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is billed in 1-second increments, with a minimum of 10 minutes. For more information, see [DB instance classes \(p. 10\)](#).
- Storage (per GiB per month) – Storage capacity that you have provisioned to your DB instance. If you scale your provisioned storage capacity within the month, your bill is prorated. For more information, see [Amazon RDS DB instance storage \(p. 64\)](#).
- I/O requests (per 1 million requests per month) – Total number of storage I/O requests that you have made in a billing cycle, for Amazon RDS magnetic storage only.
- Provisioned IOPS (per IOPS per month) – Provisioned IOPS rate, regardless of IOPS consumed, for Amazon RDS Provisioned IOPS (SSD) and General Purpose (SSD) gp3 storage. Provisioned storage for EBS volumes are billed in 1-second increments, with a minimum of 10 minutes.
- Backup storage (per GiB per month) – *Backup storage* is the storage that is associated with automated database backups and any active database snapshots that you have taken. Increasing your backup retention period or taking additional database snapshots increases the backup storage consumed by your database. Per second billing doesn't apply to backup storage (metered in GB-month).

For more information, see [Backing up and restoring an Amazon RDS DB instance \(p. 426\)](#).

- Data transfer (per GB) – Data transfer in and out of your DB instance from or to the internet and other AWS Regions.

Amazon RDS provides the following purchasing options to enable you to optimize your costs based on your needs:

- **On-Demand instances** – Pay by the hour for the DB instance hours that you use. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is now billed in 1-second increments, with a minimum of 10 minutes.
- **Reserved instances** – Reserve a DB instance for a one-year or three-year term and get a significant discount compared to the on-demand DB instance pricing. With Reserved Instance usage, you can launch, delete, start, or stop multiple instances within an hour and get the Reserved Instance benefit for all of the instances.

For Amazon RDS pricing information, see the [Amazon RDS pricing page](#).

Topics

- [On-Demand DB instances for Amazon RDS \(p. 139\)](#)
- [Reserved DB instances for Amazon RDS \(p. 140\)](#)

On-Demand DB instances for Amazon RDS

Amazon RDS on-demand DB instances are billed based on the class of the DB instance (for example, db.t2.small or db.m4.large). For Amazon RDS pricing information, see the [Amazon RDS product page](#).

Billing starts for a DB instance as soon as the DB instance is available. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. Amazon RDS usage is billed in one-second increments, with a minimum of 10 minutes. In the case of billable configuration change, such as scaling compute or storage capacity, you're charged a 10-minute minimum. Billing continues until the DB instance terminates, which occurs when you delete the DB instance or if the DB instance fails.

If you no longer want to be charged for your DB instance, you must stop or delete it to avoid being billed for additional DB instance hours. For more information about the DB instance states for which you are billed, see [Viewing Amazon RDS DB instance status \(p. 516\)](#).

Stopped DB instances

While your DB instance is stopped, you're charged for provisioned storage, including Provisioned IOPS. You are also charged for backup storage, including storage for manual snapshots and automated backups within your specified retention window. You aren't charged for DB instance hours.

Multi-AZ DB instances

If you specify that your DB instance should be a Multi-AZ deployment, you're billed according to the Multi-AZ pricing posted on the Amazon RDS pricing page.

Reserved DB instances for Amazon RDS

Using reserved DB instances, you can reserve a DB instance for a one- or three-year term. Reserved DB instances provide you with a significant discount compared to on-demand DB instance pricing. Reserved DB instances are not physical instances, but rather a billing discount applied to the use of certain on-demand DB instances in your account. Discounts for reserved DB instances are tied to instance type and AWS Region.

The general process for working with reserved DB instances is: First get information about available reserved DB instance offerings, then purchase a reserved DB instance offering, and finally get information about your existing reserved DB instances.

Overview of reserved DB instances

When you purchase a reserved DB instance in Amazon RDS, you purchase a commitment to getting a discounted rate, on a specific DB instance type, for the duration of the reserved DB instance. To use an Amazon RDS reserved DB instance, you create a new DB instance just like you do for an on-demand instance. The new DB instance that you create must match the specifications of the reserved DB instance. If the specifications of the new DB instance match an existing reserved DB instance for your account, you are billed at the discounted rate offered for the reserved DB instance. Otherwise, the DB instance is billed at an on-demand rate.

You can modify a reserved DB instance. If the modification is within the specifications of the reserved DB instance, part or all of the discount still applies to the modified DB instance. If the modification is outside the specifications, such as changing the instance class, the discount no longer applies. For more information, see [Size-flexible reserved DB instances \(p. 141\)](#).

For more information about reserved DB instances, including pricing, see [Amazon RDS reserved instances](#).

Offering types

Reserved DB instances are available in three varieties—No Upfront, Partial Upfront, and All Upfront—that let you optimize your Amazon RDS costs based on your expected usage.

No Upfront

This option provides access to a reserved DB instance without requiring an upfront payment. Your No Upfront reserved DB instance bills a discounted hourly rate for every hour within the term, regardless of usage, and no upfront payment is required. This option is only available as a one-year reservation.

Partial Upfront

This option requires a part of the reserved DB instance to be paid upfront. The remaining hours in the term are billed at a discounted hourly rate, regardless of usage. This option is the replacement for the previous Heavy Utilization option.

All Upfront

Full payment is made at the start of the term, with no other costs incurred for the remainder of the term regardless of the number of hours used.

If you are using consolidated billing, all the accounts in the organization are treated as one account. This means that all accounts in the organization can receive the hourly cost benefit of reserved DB instances that are purchased by any other account. For more information about consolidated billing, see [Amazon RDS reserved DB instances](#) in the *AWS Billing and Cost Management User Guide*.

Size-flexible reserved DB instances

When you purchase a reserved DB instance, one thing that you specify is the instance class, for example db.r5.large. For more information about instance classes, see [DB instance classes \(p. 10\)](#).

If you have a DB instance, and you need to scale it to larger capacity, your reserved DB instance is automatically applied to your scaled DB instance. That is, your reserved DB instances are automatically applied across all DB instance class sizes. Size-flexible reserved DB instances are available for DB instances with the same AWS Region and database engine. Size-flexible reserved DB instances can only scale in their instance class type. For example, a reserved DB instance for a db.r5.large can apply to a db.r5.xlarge, but not to a db.r6g.large, because db.r5 and db.r6g are different instance class types.

Reserved DB instance benefits also apply for both Multi-AZ and Single-AZ configurations. Flexibility means that you can move freely between configurations within the same DB instance class type. For example, you can move from a Single-AZ deployment running on one large DB instance (four normalized units) to a Multi-AZ deployment running on two small DB instances ($2 \times 2 = 4$ normalized units).

Size-flexible reserved DB instances are available for the following Amazon RDS database engines:

- MariaDB
- MySQL
- Oracle, Bring Your Own License
- PostgreSQL

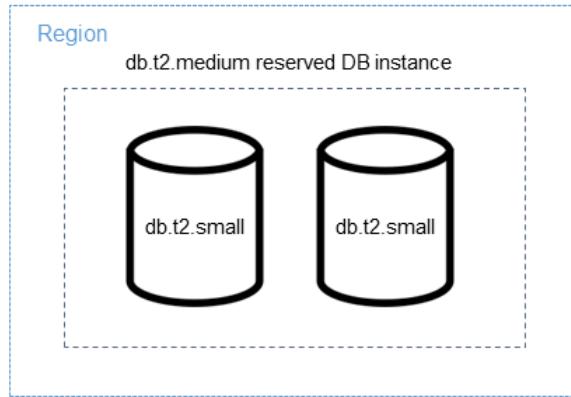

For details about using size-flexible reserved instances with Aurora, see [Reserved DB instances for Aurora](#).

You can compare usage for different reserved DB instance sizes by using normalized units. For example, one unit of usage on two db.r3.large DB instances is equivalent to eight normalized units of usage on one db.r3.small. The following table shows the number of normalized units for each DB instance size.

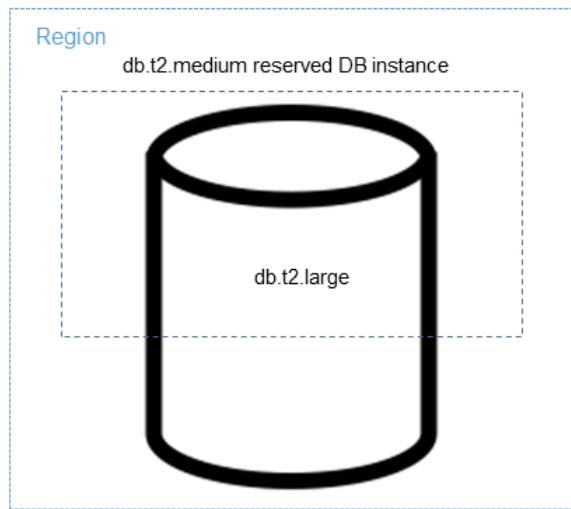

Instance size	Single-AZ normalized units	Multi-AZ normalized units
micro	0.5	1
small	1	2
medium	2	4
large	4	8
xlarge	8	16
2xlarge	16	32
4xlarge	32	64
6xlarge	48	96
8xlarge	64	128
10xlarge	80	160
12xlarge	96	192
16xlarge	128	256
24xlarge	192	384

Instance size	Single-AZ normalized units	Multi-AZ normalized units
32xlarge	256	512

For example, suppose that you purchase a db.t2.medium reserved DB instance, and you have two running db.t2.small DB instances in your account in the same AWS Region. In this case, the billing benefit is applied in full to both instances.

Alternatively, if you have one db.t2.large instance running in your account in the same AWS Region, the billing benefit is applied to 50 percent of the usage of the DB instance.

Reserved DB instance billing example

The price for a reserved DB instance doesn't include regular costs associated with storage, backups, and I/O. The following example illustrates the total cost per month for a reserved DB instance:

- An RDS for MySQL reserved Single-AZ db.r4.large DB instance class in US East (N. Virginia) with the No Upfront option at a cost of \$0.12 for the instance, or \$90 per month
- 400 GiB of General Purpose SSD (gp2) storage at a cost of 0.115 per GiB per month, or \$45.60 per month
- 600 GiB of backup storage at \$0.095, or \$19 per month (400 GiB free)

Add all of these options (\$90 + \$45.60 + \$19) with the reserved DB instance, and the total cost per month is \$154.60.

If you chose to use an on-demand DB instance instead of a reserved DB instance, an RDS for MySQL Single-AZ db.r4.large DB instance class in US East (N. Virginia) costs \$0.1386 per hour, or \$101.18 per month. So, for an on-demand DB instance, add all of these options (\$101.18 + \$45.60 + \$19), and the total cost per month is \$165.78. You save a little over \$11 per month by using the reserved DB instance.

Note

The prices in this example are sample prices and might not match actual prices. For Amazon RDS pricing information, see the [Amazon RDS product page](#).

Deleting a reserved DB instance

The terms for a reserved DB instance involve a one-year or three-year commitment. You can't cancel a reserved DB instance. However, you can delete a DB instance that is covered by a reserved DB instance discount. The process for deleting a DB instance that is covered by a reserved DB instance discount is the same as for any other DB instance.

You're billed for the upfront costs regardless of whether you use the resources.

If you delete a DB instance that is covered by a reserved DB instance discount, you can launch another DB instance with compatible specifications. In this case, you continue to get the discounted rate during the reservation term (one or three years).

Working with reserved DB instances

You can use the AWS Management Console, the AWS CLI, and the RDS API to work with reserved DB instances.

Console

You can use the AWS Management Console to work with reserved DB instances as shown in the following procedures.

To get pricing and information about available reserved DB instance offerings

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Reserved instances**.
3. Choose **Purchase Reserved DB Instance**.
4. For **Product description**, choose the DB engine and licensing type.
5. For **DB instance class**, choose the DB instance class.
6. For **Deployment Option**, choose whether you want a Multi-AZ deployment.
7. For **Term**, choose the length of time you want the DB instance reserved.
8. For **Offering type**, choose the offering type.

After you select the offering type, you can see the pricing information.

Important

Choose **Cancel** to avoid purchasing the reserved DB instance and incurring any charges.

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering as shown in the following procedure.

To purchase a reserved DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Reserved instances**.

3. Choose **Purchase reserved DB instance**.

4. For **Product description**, choose the DB engine and licensing type.

5. For **DB instance class**, choose the DB instance class.

6. For **Multi-AZ deployment**, choose whether you want a Multi-AZ deployment.

7. For **Term**, choose the length of time you want the DB instance reserved.

8. For **Offering type**, choose the offering type.

After you choose the offering type, you can see the pricing information.

9. (Optional) You can assign your own identifier to the reserved DB instances that you purchase to help you track them. For **Reserved Id**, type an identifier for your reserved DB instance.

10. Choose **Submit**.

Your reserved DB instance is purchased, then displayed in the **Reserved instances** list.

After you have purchased reserved DB instances, you can get information about your reserved DB instances as shown in the following procedure.

To get information about reserved DB instances for your AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the Navigation pane, choose **Reserved instances**.

The reserved DB instances for your account appear. To see detailed information about a particular reserved DB instance, choose that instance in the list. You can then see detailed information about that instance in the detail pane at the bottom of the console.

AWS CLI

You can use the AWS CLI to work with reserved DB instances as shown in the following examples.

Example of getting available reserved DB instance offerings

To get information about available reserved DB instance offerings, call the AWS CLI command `describe-reserved-db-instances-offerings`.

```
aws rds describe-reserved-db-instances-offerings
```

This call returns output similar to the following:

OFFERING	OfferingId	Class	Multi-AZ	Duration	Fixed
Price	Usage Price	Description	Offering Type		
OFFERING	438012d3-4052-4cc7-b2e3-8d3372e0e706	db.r3.large	y	1y	1820.00
USD	0.368	USD mysql	Partial Upfront		
OFFERING	649fd0c8-cf6d-47a0-bfa6-060f8e75e95f	db.r3.small	n	1y	227.50
USD	0.046	USD mysql	Partial Upfront		
OFFERING	123456cd-ab1c-47a0-bfa6-12345667232f	db.r3.small	n	1y	162.00
USD	0.00	USD mysql	All Upfront		
Recurring Charges:		Amount	Currency	Frequency	
Recurring Charges:		0.123	USD	Hourly	

OFFERING	123456cd-ab1c-37a0-bfa6-12345667232d	db.r3.large	y	1y	700.00
USD	0.00 USD	mysql	All	Upfront	
Recurring Charges:	Amount	Currency	Frequency		
Recurring Charges:	1.25	USD	Hourly		
OFFERING	123456cd-ab1c-17d0-bfa6-12345667234e	db.r3.xlarge	n	1y	4242.00
USD	2.42 USD	mysql	No	Upfront	

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering.

To purchase a reserved DB instance, use the AWS CLI command [purchase-reserved-db-instances-offering](#) with the following parameters:

- **--reserved-db-instances-offering-id** – The ID of the offering that you want to purchase. See the preceding example to get the offering ID.
- **--reserved-db-instance-id** – You can assign your own identifier to the reserved DB instances that you purchase to help track them.

Example of purchasing a reserved DB instance

The following example purchases the reserved DB instance offering with ID **649fd0c8-cf6d-47a0-bfa6-060f8e75e95f**, and assigns the identifier of **MyReservation**.

For Linux, macOS, or Unix:

```
aws rds purchase-reserved-db-instances-offering \
--reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f \
--reserved-db-instance-id MyReservation
```

For Windows:

```
aws rds purchase-reserved-db-instances-offering ^
--reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f ^
--reserved-db-instance-id MyReservation
```

The command returns output similar to the following:

RESERVATION	ReservationId	Class	Multi-AZ	Start Time	Duration
Fixed Price	Usage Price	Count	State	Description	Offering Type
RESERVATION	MyReservation	db.r3.small	y	2011-12-19T00:30:23.247Z	1y
455.00	USD	0.092	1	payment-pending	mysql Partial Upfront

After you have purchased reserved DB instances, you can get information about your reserved DB instances.

To get information about reserved DB instances for your AWS account, call the AWS CLI command [describe-reserved-db-instances](#), as shown in the following example.

Example of getting your reserved DB instances

```
aws rds describe-reserved-db-instances
```

The command returns output similar to the following:

RESERVATION	ReservationId	Class	Multi-AZ	Start Time	Duration
Fixed Price	Usage Price	Count	State	Description	Offering Type
RESERVATION	MyReservation	db.r3.small	y	2011-12-09T23:37:44.720Z	1y
455.00	USD	0.092	1	retired	mysql Partial Upfront

RDS API

You can use the RDS API to work with reserved DB instances:

- To get information about available reserved DB instance offerings, call the Amazon RDS API operation [DescribeReservedDBInstancesOfferings](#).
 - After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering. Call the [PurchaseReservedDBInstancesOffering](#) RDS API operation with the following parameters:
 - `--reserved-db-instances-offering-id` – The ID of the offering that you want to purchase.
 - `--reserved-db-instance-id` – You can assign your own identifier to the reserved DB instances that you purchase to help track them.
 - After you have purchased reserved DB instances, you can get information about your reserved DB instances. Call the [DescribeReservedDBInstances](#) RDS API operation.

Viewing the billing for your reserved DB instances

You can view the billing for your reserved DB instances in the Billing Dashboard in the AWS Management Console.

To view reserved DB instance billing

1. Sign in to the AWS Management Console.
 2. From the **account menu** at the upper right, choose **Billing Dashboard**.
 3. Choose **Bill Details** at the upper right of the dashboard.
 4. Under **AWS Service Charges**, expand **Relational Database Service**.
 5. Expand the AWS Region where your reserved DB instances are, for example **US West (Oregon)**.

Your reserved DB instances and their hourly charges for the current month are shown under **Amazon Relational Database Service for Database Engine Reserved Instances**.

The reserved DB instance in this example was purchased All Upfront, so there are no hourly charges.

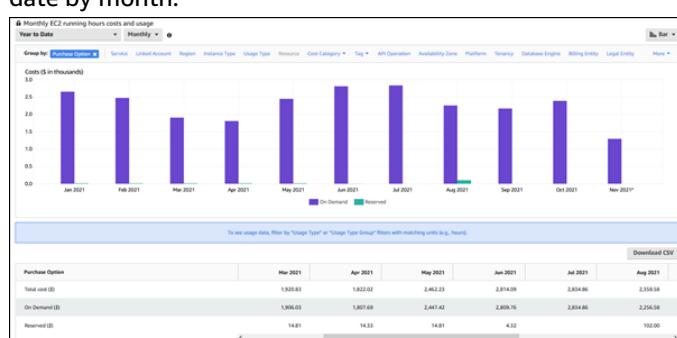

- 6 Choose the **Cost Explorer** (bar graph) icon next to the **Reserved Instances** heading.

The Cost Explorer displays the **Monthly EC2 running hours costs and usage** graph.

7. Clear the **Usage Type Group** filter to the right of the graph.

- 8 Choose the time period and time unit for which you want to examine usage costs

The following example shows usage costs for on-demand and reserved DB instances for the year to date by month.

The reserved DB instance costs from January through June 2021 are monthly charges for a Partial Upfront instance, while the cost in August 2021 is a one-time charge for an All Upfront instance.

The reserved instance discount for the Partial Upfront instance expired in June 2021, but the DB instance wasn't deleted. After the expiration date, it was simply charged at the on-demand rate.

Setting up for Amazon RDS

Before you use Amazon Relational Database Service for the first time, complete the following tasks.

Topics

- [Sign up for an AWS account \(p. 148\)](#)
- [Create an administrative user \(p. 148\)](#)
- [Create IAM user access keys \(p. 149\)](#)
- [Determine requirements \(p. 150\)](#)
- [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#)

If you already have an AWS account, know your Amazon RDS requirements, and prefer to use the defaults for IAM and VPC security groups, skip ahead to [Getting started with Amazon RDS \(p. 153\)](#).

Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

1. Open <https://portal.aws.amazon.com/billing/signup>.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, [assign administrative access to an administrative user](#), and use only the root user to perform [tasks that require root user access](#).

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to <https://aws.amazon.com/> and choosing **My Account**.

Create an administrative user

After you sign up for an AWS account, create an administrative user so that you do not use the root user for everyday tasks.

Secure your AWS account root user

1. Sign in to the [AWS Management Console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.
For help signing in using root user, see [Signing in as the root user](#) in the *AWS Sign-In User Guide*.
2. Turn on multi-factor authentication (MFA) for your root user.

For instructions, see [Enable a virtual MFA device for your AWS account root user \(console\)](#) in the *IAM User Guide*.

Create an administrative user

- For your daily administrative tasks, assign administrative access to an administrative user in AWS IAM Identity Center (successor to AWS Single Sign-On).

For instructions, see [Getting started](#) in the *AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide*.

Sign in as the administrative user

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see [Signing in to the AWS access portal](#) in the *AWS Sign-In User Guide*.

Create IAM user access keys

Access keys consist of an access key ID and secret access key, which are used to sign programmatic requests that you make to AWS. If you don't have access keys, you can create them from the AWS Management Console. As a best practice, do not use the AWS account root user access keys for any task where it's not required. Instead, [create a new administrator IAM user](#) with access keys for yourself.

The only time that you can view or download the secret access key is when you create the keys. You cannot recover them later. However, you can create new access keys at any time. You must also have permissions to perform the required IAM actions. For more information, see [Permissions required to access IAM resources](#) in the *IAM User Guide*.

To create access keys for an IAM user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
 2. In the navigation pane, choose **Users**.
 3. Choose the name of the user whose access keys you want to create, and then choose the **Security credentials** tab.
 4. In the **Access keys** section, choose **Create access key**.
 5. To view the new access key pair, choose **Show**. You will not have access to the secret access key again after this dialog box closes. Your credentials will look something like this:
 - Access key ID: AKIAIOSFODNN7EXAMPLE
 - Secret access key: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
 6. To download the key pair, choose **Download .csv file**. Store the keys in a secure location. You will not have access to the secret access key again after this dialog box closes.
 7. After you download the .csv file, choose **Close**. When you create an access key, the key pair is active by default, and you can use the pair right away.
- Keep the keys confidential in order to protect your AWS account and never email them. Do not share them outside your organization, even if an inquiry appears to come from AWS or Amazon.com. No one who legitimately represents Amazon will ever ask you for your secret key.

Determine requirements

The basic building block of Amazon RDS is the DB instance. In a DB instance, you create your databases. A DB instance provides a network address called an *endpoint*. Your applications use this endpoint to connect to your DB instance. When you create a DB instance, you specify details like storage, memory, database engine and version, network configuration, security, and maintenance periods. You control network access to a DB instance through a security group.

Before you create a DB instance and a security group, you must know your DB instance and network needs. Here are some important things to consider:

- **Resource requirements** – What are the memory and processor requirements for your application or service? You use these settings to help you determine what DB instance class to use. For specifications about DB instance classes, see [DB instance classes \(p. 10\)](#).
- **VPC, subnet, and security group** – Your DB instance will most likely be in a virtual private cloud (VPC). To connect to your DB instance, you need to set up security group rules. These rules are set up differently depending on what kind of VPC you use and how you use it. For example, you can use: a default VPC or a user-defined VPC.

The following list describes the rules for each VPC option:

- **Default VPC** – If your AWS account has a default VPC in the current AWS Region, that VPC is configured to support DB instances. If you specify the default VPC when you create the DB instance, do the following:
 - Make sure to create a *VPC security group* that authorizes connections from the application or service to the Amazon RDS DB instance. Use the **Security Group** option on the VPC console or the AWS CLI to create VPC security groups. For information, see [Step 3: Create a VPC security group \(p. 2114\)](#).
 - Specify the default DB subnet group. If this is the first DB instance you have created in this AWS Region, Amazon RDS creates the default DB subnet group when it creates the DB instance.
- **User-defined VPC** – If you want to specify a user-defined VPC when you create a DB instance, be aware of the following:
 - Make sure to create a *VPC security group* that authorizes connections from the application or service to the Amazon RDS DB instance. Use the **Security Group** option on the VPC console or the AWS CLI to create VPC security groups. For information, see [Step 3: Create a VPC security group \(p. 2114\)](#).
 - The VPC must meet certain requirements in order to host DB instances, such as having at least two subnets, each in a separate Availability Zone. For information, see [Amazon VPC VPCs and Amazon RDS \(p. 2103\)](#).
 - Make sure to specify a DB subnet group that defines which subnets in that VPC can be used by the DB instance. For information, see the DB subnet group section in [Working with a DB instance in a VPC \(p. 2104\)](#).
- **High availability** – Do you need failover support? On Amazon RDS, a Multi-AZ deployment creates a primary DB instance and a secondary standby DB instance in another Availability Zone for failover support. We recommend Multi-AZ deployments for production workloads to maintain high availability. For development and test purposes, you can use a deployment that isn't Multi-AZ. For more information, see [Multi-AZ deployments for high availability \(p. 121\)](#).
- **IAM policies** – Does your AWS account have policies that grant the permissions needed to perform Amazon RDS operations? If you are connecting to AWS using IAM credentials, your IAM account must

have IAM policies that grant the permissions required to perform Amazon RDS operations. For more information, see [Identity and access management for Amazon RDS \(p. 2016\)](#).

- **Open ports** – What TCP/IP port does your database listen on? The firewalls at some companies might block connections to the default port for your database engine. If your company firewall blocks the default port, choose another port for the new DB instance. When you create a DB instance that listens on a port you specify, you can change the port by modifying the DB instance.
- **AWS Region** – What AWS Region do you want your database in? Having your database in close proximity to your application or web service can reduce network latency. For more information, see [Regions, Availability Zones, and Local Zones \(p. 72\)](#).
- **DB disk subsystem** – What are your storage requirements? Amazon RDS provides three storage types:
 - General Purpose (SSD)
 - Provisioned IOPS (PIOPS)
 - Magnetic (also known as standard storage)

For more information on Amazon RDS storage, see [Amazon RDS DB instance storage \(p. 64\)](#).

When you have the information you need to create the security group and the DB instance, continue to the next step.

Provide access to your DB instance in your VPC by creating a security group

VPC security groups provide access to DB instances in a VPC. They act as a firewall for the associated DB instance, controlling both inbound and outbound traffic at the DB instance level. DB instances are created by default with a firewall and a default security group that protect the DB instance.

Before you can connect to your DB instance, you must add rules to a security group that enable you to connect. Use your network and configuration information to create rules to allow access to your DB instance.

For example, suppose that you have an application that accesses a database on your DB instance in a VPC. In this case, you must add a custom TCP rule that specifies the port range and IP addresses that your application uses to access the database. If you have an application on an Amazon EC2 instance, you can use the security group that you set up for the Amazon EC2 instance.

You can configure connectivity between an Amazon EC2 instance and a DB instance when you create the DB instance. For more information, see [Configure automatic network connectivity with an EC2 instance \(p. 230\)](#).

Tip

You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. For more information, see [Configure automatic network connectivity with an EC2 instance \(p. 230\)](#).

For information about common scenarios for accessing a DB instance, see [Scenarios for accessing a DB instance in a VPC \(p. 2115\)](#).

To create a VPC security group

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc>.

Note

Make sure you are in the VPC console, not the RDS console.

2. In the upper-right corner of the AWS Management Console, choose the AWS Region where you want to create your VPC security group and DB instance. In the list of Amazon VPC resources for that AWS Region, you should see at least one VPC and several subnets. If you don't, you don't have a default VPC in that AWS Region.
3. In the navigation pane, choose **Security Groups**.
4. Choose **Create security group**.
The **Create security group** page appears.
5. In **Basic details**, enter the **Security group name** and **Description**. For **VPC**, choose the VPC that you want to create your DB instance in.
6. In **Inbound rules**, choose **Add rule**.
 - a. For **Type**, choose **Custom TCP**.
 - b. For **Port range**, enter the port value to use for your DB instance.
 - c. For **Source**, choose a security group name or type the IP address range (CIDR value) from where you access the DB instance. If you choose **My IP**, this allows access to the DB instance from the IP address detected in your browser.
7. If you need to add more IP addresses or different port ranges, choose **Add rule** and enter the information for the rule.
8. (Optional) In **Outbound rules**, add rules for outbound traffic. By default, all outbound traffic is allowed.
9. Choose **Create security group**.

You can use the VPC security group that you just created as the security group for your DB instance when you create it.

Note

If you use a default VPC, a default subnet group spanning all of the VPC's subnets is created for you. When you create a DB instance, you can select the default VPC and use **default** for **DB Subnet Group**.

After you have completed the setup requirements, you can create a DB instance using your requirements and security group. To do so, follow the instructions in [Creating an Amazon RDS DB instance \(p. 230\)](#). For information about getting started by creating a DB instance that uses a specific DB engine, see the relevant documentation in the following table.

Database engine	Documentation
MariaDB	Creating a MariaDB DB instance and connecting to a database on a MariaDB DB instance (p. 154)
Microsoft SQL Server	Creating a Microsoft SQL Server DB instance and connecting to it (p. 162)
MySQL	Creating a MySQL DB instance and connecting to a database on a MySQL DB instance (p. 172)
Oracle	Creating an Oracle DB instance and connecting to a database on an Oracle DB instance (p. 180)
PostgreSQL	Creating a PostgreSQL DB instance and connecting to a database on a PostgreSQL DB instance (p. 187)

Note

If you can't connect to a DB instance after you create it, see the troubleshooting information in [Can't connect to Amazon RDS DB instance \(p. 2141\)](#).

Getting started with Amazon RDS

In the following examples, you can find how to create and connect to a DB instance using Amazon Relational Database Service (Amazon RDS). You can create a DB instance that uses MariaDB, MySQL, Microsoft SQL Server, Oracle, or PostgreSQL.

Important

Before you can create or connect to a DB instance, make sure to complete the tasks in [Setting up for Amazon RDS \(p. 148\)](#).

Creating a DB instance and connecting to a database on a DB instance is slightly different for each of the DB engines. Choose one of the following DB engines that you want to use for detailed information on creating and connecting to the DB instance. After you have created and connected to your DB instance, there are instructions to help you delete the DB instance.

Creating a MariaDB DB instance and connecting to a database on a MariaDB DB instance

The easiest way to create a MariaDB DB instance is to use the AWS Management Console. After you create the DB instance, you can connect to a database on the DB instance. To do so, you can use command line tools such as mysql or graphical tools such as HeidiSQL.

Important

Before you can create or connect to a DB instance, make sure to complete the tasks in [Setting up for Amazon RDS \(p. 148\)](#).

Topics

- [Creating a MariaDB DB instance \(p. 154\)](#)
- [Connecting to a database on a DB instance running the MariaDB database engine \(p. 158\)](#)
- [Deleting a DB instance \(p. 161\)](#)

Creating a MariaDB DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your MariaDB databases.

You can use **Easy create** to create a DB instance running MariaDB with the AWS Management Console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. When you use **Standard create** instead of **Easy create**, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

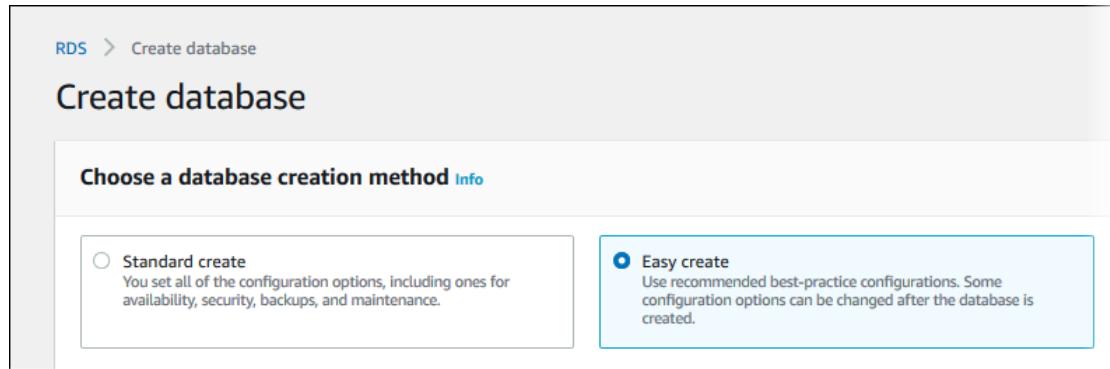

In this example, you use **Easy create** to create a DB instance running the MariaDB database engine with a db.t2.micro DB instance class.

Note

For information about creating DB instances with **Standard create**, see [Creating an Amazon RDS DB instance \(p. 230\)](#).

To create a MariaDB DB instance with **Easy create**

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.

5. In **Configuration**, choose **MariaDB**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier**, enter a name for the DB instance, or leave the default name.
8. For **Master username**, enter a name for the master user, or leave the default name.

The **Create database** page should look similar to the following image.

Create database

Choose a database creation method [Info](#)

Standard create

You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy create

Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

DB instance identifier

Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.

database-1

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Master username [Info](#)

Type a login ID for the master user of your DB instance.

9. To use an automatically generated master password for the DB instance, make sure that the **Auto generate a password** box is selected.

To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

10. (Optional) Open **View default settings for Easy create**.

▼ **View default settings for Easy create**

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use [Standard Create](#).

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-6594f31c)	No
Option Group	default:mariadb-10-4	Yes
Subnet Group	default	Yes
Automatic Backups	Enabled	Yes
VPC Security Group	sg-68184619	Yes
Publically Accessible	No	Yes
Database Port	3306	Yes
DB Instance Identifier	database-1	Yes
DB Engine Version	10.4.13	Yes
DB Parameter Group	default.mariadb10.4	Yes
Performance Insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto Minor Version Upgrade Enabled	Yes
Delete Protection	Not Enabled	Yes

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after database creation.

- To change settings with **No** in that column, use **Standard create**.
- To change settings with **Yes** in that column, either use **Standard create**, or modify the DB instance after it is created to change the settings.

The following are important considerations for changing the default settings:

- In some cases, you might want your DB instance to use a specific virtual private cloud (VPC) based on the Amazon VPC service. Or you might require a specific subnet group or security group. If so, use **Standard create** to specify these resources. You might have created these resources when you set up for Amazon RDS. For more information, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).

- If you want to be able to access the DB instance from a client outside of its VPC, use **Standard create** to set **Public access** to **Yes**.

If the DB instance should be private, leave **Public access** set to **No**.

11. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it.

If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

12. For **Databases**, choose the name of the new Maria DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **Creating** until the DB instance is ready to use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

database-1			
Summary			
DB identifier	CPU	Info	Class

Role	Current activity	Engine	Region & AZ
Instance		MariaDB	-

[Connectivity & security](#) | [Monitoring](#) | [Logs & events](#) | [Configuration](#) | [Maintenance & backups](#) | [Tags](#)

Connecting to a database on a DB instance running the MariaDB database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to a database on the DB instance. In this example, you connect to a database on a Maria DB instance using the mysql command-line tool. For more information on using MariaDB, see the [MariaDB documentation](#).

To connect to a database on a DB instance using the mysql command-line tool

1. Install a SQL client that you can use to connect to the DB instance.

You can connect to an Amazon RDS for MariaDB DB instance by using tools such as the mysql command-line client. For more information on using the mysql command-line client, see [mysql command-line client](#) in the MariaDB documentation. One GUI-based application that you can use

to connect is Heidi. For more information, see the [Download HeidiSQL](#) page. For information about installing MySQL (including the mysql command-line client), see [Installing and upgrading MySQL](#).

2. Make sure that your DB instance is associated with a security group that provides access to it. For more information, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).

If you didn't specify the appropriate security group when you created the DB instance, you can modify the DB instance to change its security group. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

If your DB instance is publicly accessible, make sure its associated security group has inbound rules for the IP addresses that you want to access it. If your DB instance is private, make sure its associated security group has inbound rules for the security group of each resource to access it. An example is the security group for an Amazon EC2 instance.

3. Find the endpoint (DNS name) and port number for your DB instance.
 - a. Open the RDS console and then choose **Databases** to display a list of your DB instances.
 - b. Choose the Maria DB instance name to display its details.
 - c. On the **Connectivity & security** tab, copy the endpoint. Also note the port number. You need both the endpoint and the port number to connect to the DB instance.

The screenshot shows the Amazon RDS console interface. At the top, the navigation path is RDS > Databases > mydb. Below this, the database name "mydb" is displayed in a large font. A "Summary" section provides basic information: DB identifier (mydb), Role (Instance), CPU usage (2.33%), and Current activity (0 Connections). Below the summary, there are tabs for Connectivity & security, Monitoring, Logs & events, and Configuration. The Connectivity & security tab is selected. Under this tab, the "Endpoint & port" section is highlighted with a red oval. It shows the Endpoint as "mydb. [REDACTED].us-east-1.rds.amazonaws.com" and the Port as "3306". To the right of the endpoint, there is a vertical column of network-related information: Network (Available), us-east-1, VPC (vpc-6E), and Subnet (default).

4. Enter the following command at a command prompt on a client computer to connect to a database on a Maria DB instance. Substitute the DNS name (endpoint) for your DB instance for <endpoint>. In addition, substitute the master user name that you used for <mymasteruser> and provide the master password that you used when prompted for a password.

```
PROMPT> mysql -h <endpoint> -P 3306 -u <mymasteruser> -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MariaDB monitor. Commands end with ; or \g.  
Your MariaDB connection id is 31
```

```
Server version: 10.5.15-MariaDB-log Source distribution
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.
Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.
MariaDB [(none)]>
```

For more information about connecting to a MariaDB DB instance, see [Connecting to a DB instance running the MariaDB database engine \(p. 986\)](#). If you can't connect to your DB instance, see [Can't connect to Amazon RDS DB instance \(p. 2141\)](#).

Deleting a DB instance

After you connect to the sample DB instance that you created, delete the DB instance so you're no longer charged for it.

To delete a DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance you want to delete.
4. For **Actions**, choose **Delete**.
5. For **Create final snapshot?**, choose **No**, and select the acknowledgment.
6. Choose **Delete**.

Creating a Microsoft SQL Server DB instance and connecting to it

The basic building block of Amazon RDS is the DB instance. Your Amazon RDS DB instance is similar to your on-premises Microsoft SQL Server. After you create your SQL Server DB instance, you can add one or more custom databases to it.

Important

Before you can create or connect to a DB instance, make sure to complete the tasks in [Setting up for Amazon RDS \(p. 148\)](#).

In this topic, you create a sample SQL Server DB instance. You then connect to the DB instance and run a simple query. Finally, you delete the sample DB instance.

Creating a sample SQL Server DB instance

You can use **Easy create** to create a DB instance running Microsoft SQL Server with the AWS Management Console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. When you use **Standard create** instead of **Easy create**, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

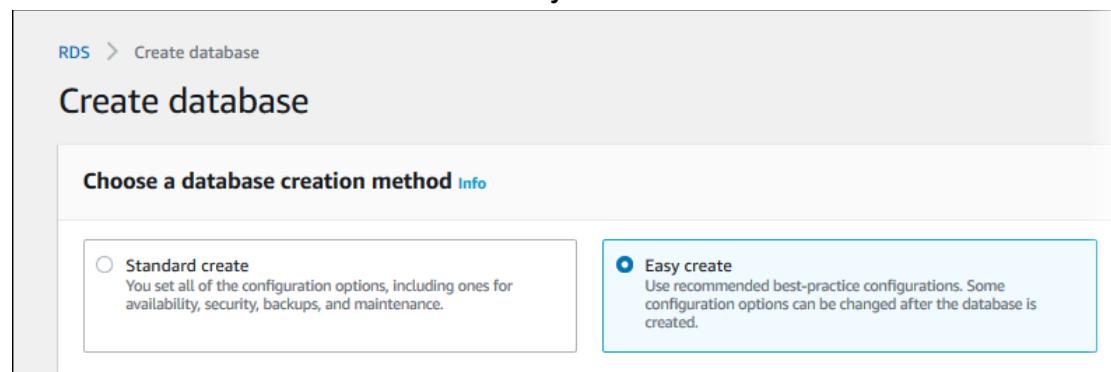

In this example, you use **Easy create** to create a DB instance running the Microsoft SQL Server database engine with a db.t2.micro DB instance class.

Note

For information about creating DB instances with **Standard create**, see [Creating an Amazon RDS DB instance \(p. 230\)](#).

To create a Microsoft SQL Server DB instance with Easy create

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.

5. From **Engine type**, choose **Microsoft SQL Server**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier**, enter **sample-instance**, or leave the default name.

8. For **Master username**, enter a name for the master user, or leave the default name.
9. To use an automatically generated master password for the DB instance, select the **Auto generate a password** box.

To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

The **Create database** page should look similar to the following image.

Create database

Choose a database creation method [Info](#)

sample-instance

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Master username [Info](#)

10. (Optional) Expand **View default settings for Easy create.**

▼ View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use [Standard Create](#).

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	tutorial-vpc (vpc-0c55993b496995ef9)	No
Option Group	default:sqlserver-ex-14-00	Yes
Subnet Group	tutorial-db-subnet-group	Yes
Automatic Backups	Enabled	Yes
VPC Security Group	sg-087f3797a22d126d9	Yes
Publicly Accessible	No	Yes
Database Port	1433	Yes
DB Instance Identifier	sample-instance	Yes
DB Engine Version	14.00.3381.3.v1	Yes
DB Parameter Group	default.sqlserver-ex-14.0	Yes
Performance Insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto Minor Version Upgrade Enabled	Yes
Delete Protection	Not Enabled	Yes

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after database creation.

- To change settings with **No** in that column, use [Standard create](#).
- To change settings with **Yes** in that column, either use [Standard create](#), or modify the DB instance after it is created to change the settings.

The following are important considerations for changing the default settings:

- In some cases, you might want your DB instance to use a specific virtual private cloud (VPC) based on the Amazon VPC service. Or you might require a specific subnet group or security group. If so, use [Standard create](#) to specify these resources. You might have created these resources when you set up for Amazon RDS. For more information, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).

- If you want to be able to access the DB instance from a client outside of its VPC, use **Standard create** to set **Public access** to **Yes**.

If the DB instance should be private, leave **Public access** set to **No**.

11. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it.

If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

12. For **Databases**, choose the name of the new Microsoft SQL Server DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **Creating** until the DB instance is ready to use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

The screenshot shows the RDS console with the path 'RDS > Databases > sample-instance'. The main title is 'sample-instance'. On the right, there are 'Modify' and 'Actions' buttons. Below the title, there's a 'Summary' section with a table. The 'Status' column for the first row (DB identifier: sample-instance) is circled in red and shows 'Creating'. Other columns show CPU: -, Class: db.t2.micro, Role: Instance, Current activity: -, Engine: SQL Server Express Edition, and Region & AZ: us-east-2b. At the bottom, tabs for 'Connectivity & security' (which is selected), 'Monitoring', 'Logs & events', 'Configuration', 'Maintenance & backups', and 'Tags' are visible.

DB identifier	CPU	Status	Class
sample-instance	-	Creating	db.t2.micro
Role	Current activity	Engine	Region & AZ
Instance	-	SQL Server Express Edition	us-east-2b

Connecting to your sample SQL Server DB instance

In the following procedure, you connect to your sample DB instance by using Microsoft SQL Server Management Studio (SSMS).

Before you begin, your database should have a status of **Available**. If it has a status of **Creating** or **Backing-up**, wait until it shows **Available**. The status updates without requiring you to refresh the page. This process can take up to 20 minutes.

Also, make sure that you have SSMS installed. You can also connect to RDS for SQL Server by using a different tool, such as an add-in for your development environment or some other database tool. However, this tutorial only covers using SSMS. To download a standalone version of this SSMS, see [Download SQL Server Management Studio \(SSMS\)](#) in the Microsoft documentation.

To connect to a DB instance using SSMS

1. Make sure that your DB instance is associated with a security group that provides access to it. For more information, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).

If you didn't specify the appropriate security group when you created the DB instance, you can modify the DB instance to change its security group. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

If your DB instance is publicly accessible, make sure its associated security group has inbound rules for the IP addresses that you want to access it. If your DB instance is private, make sure its associated security group has inbound rules for the security group of each resource to access it. An example is the security group for an Amazon EC2 instance.

2. Find the DNS name and port number for your DB instance.
 - a. Open the RDS console, and then choose **Databases** to display a list of your DB instances.
 - b. Hover your mouse cursor over the name **sample-instance**, which is blue. When you do this, the mouse cursor changes into a selection icon (for example, a pointing hand). Also, the DB instance name becomes underlined.

Click on the DB instance name to choose it. The screen changes to display the information for the DB instance you choose.

- c. On the **Connectivity** tab, which opens by default, copy the endpoint. The **Endpoint** looks something like this: `sample-instance.123456789012.us-east-2.rds.amazonaws.com`. Also, note the port number. The default port for SQL Server is 1433. If yours is different, write it down.

The screenshot shows the Amazon RDS console interface. At the top, the navigation path is RDS > Databases > sample-instance. Below this, the database name "sample-instance" is displayed in large bold letters. A "Summary" section provides key metrics: DB identifier (sample-instance), CPU usage (44.50%), Role (Instance), and Current activity (0 Connect). Below the summary, there are three tabs: Connectivity & security (selected), Monitoring, and Logs & events. The Connectivity & security tab displays the endpoint and port information, which is circled in red.

DB identifier	CPU
sample-instance	44.50%

Role	Current activity
Instance	0 Connect

Connectivity & security

Endpoint & port

Endpoint: sample-instance. .us-east-2.rds.amazonaws.com

Port: 1433

3. Start SQL Server Management Studio.

The **Connect to Server** dialog box appears.

4. Provide the following information for your sample DB instance:

a. For **Server type**, choose **Database Engine**.

b. For **Server name**, enter the DNS name, followed by a comma and the port number (the default port is 1433). For example, your server name should look like the following.

sample-instance.*abc2defghije.us-west-2.rds.amazonaws.com*,1433

c. For **Authentication**, choose **SQL Server Authentication**.

- d. For **Login**, enter the user name that you chose to use for your sample DB instance. This is also known as the master user name.
 - e. For **Password**, enter the password that you chose earlier for your sample DB instance. This is also known as the master user password.
5. Choose **Connect**.

After a few moments, SSMS connects to your DB instance.

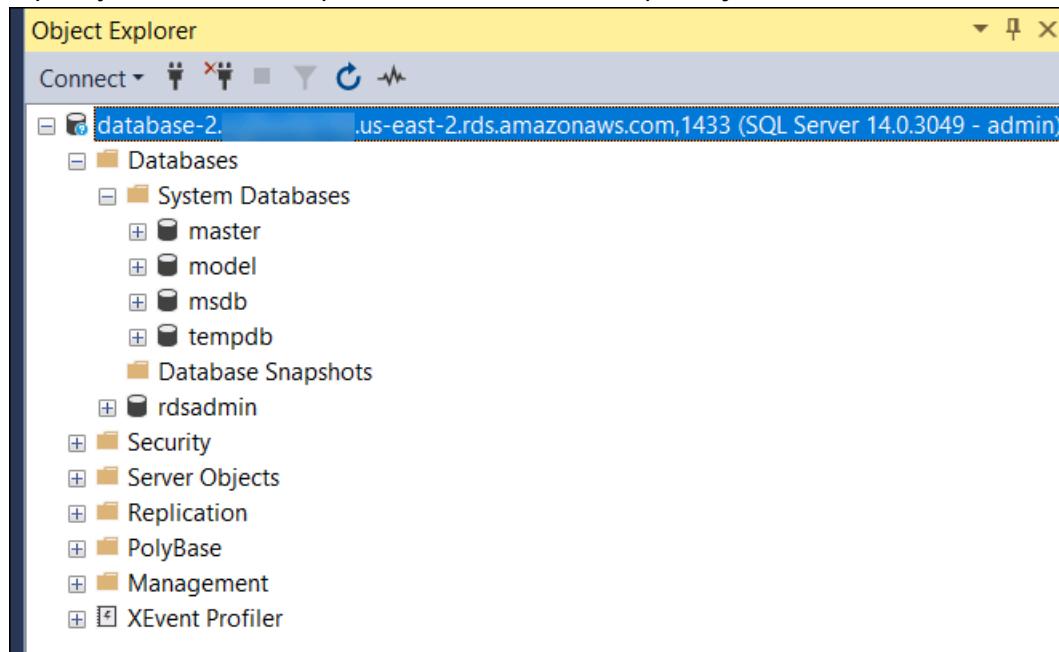

For more information about connecting to a Microsoft SQL Server DB instance, see [Connecting to a DB instance running the Microsoft SQL Server database engine \(p. 1084\)](#). For information on connection issues, see [Can't connect to Amazon RDS DB instance \(p. 2141\)](#).

Exploring your sample SQL Server DB instance

In this procedure, you continue the previous procedure and explore your sample DB instance by using Microsoft SQL Server Management Studio (SSMS).

To explore a DB instance using SSMS

1. Your SQL Server DB instance comes with SQL Server's standard built-in system databases (master, model, msdb, and tempdb). To explore the system databases, do the following:
 - a. In SSMS, on the **View** menu, choose **Object Explorer**.
 - b. Expand your DB instance, expand **Databases**, and then expand **System Databases** as shown.

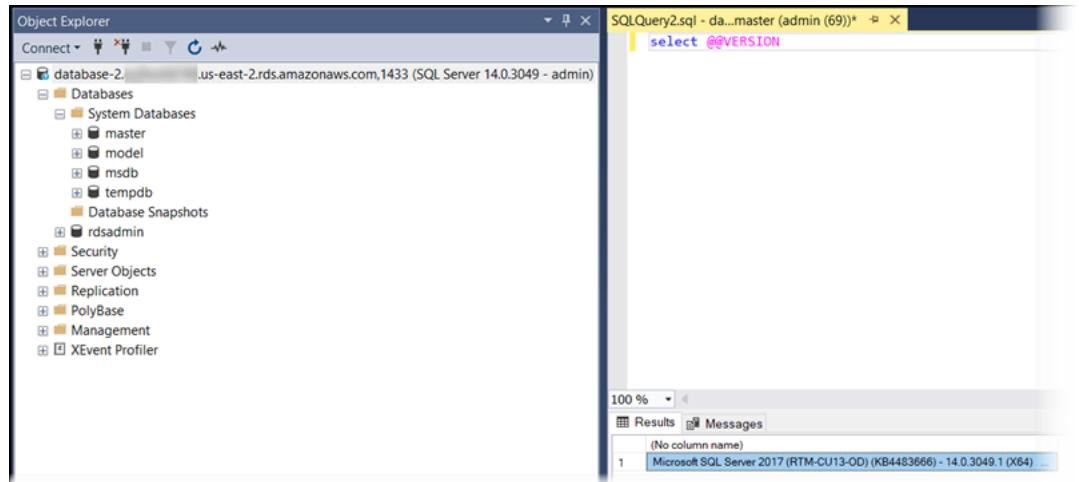

Your SQL Server DB instance also comes with a database named `rdsadmin`. Amazon RDS uses this database to store the objects that it uses to manage your database. The `rdsadmin` database also includes stored procedures that you can run to perform advanced tasks.

2. Start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your sample DB instance, do the following:
 - a. In SSMS, on the **File** menu point to **New** and then choose **Query with Current Connection**.

- b. Enter the following SQL query.

```
select @@VERSION
```

- c. Run the query. SSMS returns the SQL Server version of your Amazon RDS DB instance.

Deleting your sample DB instance

After you're done exploring your sample DB instance, delete it so that you're no longer charged for it.

To delete a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the button next to **sample-instance**, or whatever you named your sample DB instance.
4. From **Actions**, choose **Delete**.
5. If you see a message that says **This database has deletion protection option enabled**, follow these steps:
 - a. Choose **Modify**.
 - b. On the **Deletion protection** card (near the bottom of the page), clear the box next to **Enable deletion protection**. Then choose **Continue**.
 - c. On the **Scheduling of modifications** card, choose **Apply immediately**. Then choose **Modify DB instance**.
 - d. Try again to delete the instance by choosing **Delete** from the **Actions** menu.
6. Clear the box for **Create final snapshot**. Because this isn't a production database, you don't need to save a copy of it.
7. Verify that you selected the correct database to delete. The name "sample-instance" displays in the title of the screen: **Delete sample-instance instance?**

If you don't recognize the name of your sample instance in the title, choose **Cancel** and start over.
8. To confirm that you want to permanently delete the database that is displayed in the title of this screen, do the following:
 - Select the box to confirm: **I acknowledge that upon instance deletion, automated backups, including system snapshots and point-in-time recovery, will no longer be available.**

- Enter "**delete me**" into the box **To confirm deletion, type *delete me* into the field.**
- Choose **Delete**. This action can't be undone.

The database shows a status of **Deleting** until deletion is complete.

Creating a MySQL DB instance and connecting to a database on a MySQL DB instance

The easiest way to create a DB instance is to use the AWS Management Console. After you create the DB instance, you can use standard MySQL utilities such as MySQL Workbench to connect to a database on the DB instance.

Important

Before you can create or connect to a DB instance, make sure to complete the tasks in [Setting up for Amazon RDS \(p. 148\)](#).

Topics

- [Creating a MySQL DB instance \(p. 172\)](#)
- [Connecting to a database on a DB instance running the MySQL database engine \(p. 176\)](#)
- [Deleting a DB instance \(p. 179\)](#)

Creating a MySQL DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your MySQL databases.

You can use **Easy create** to create a DB instance running MySQL with the AWS Management Console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. When you use **Standard create** instead of **Easy create**, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

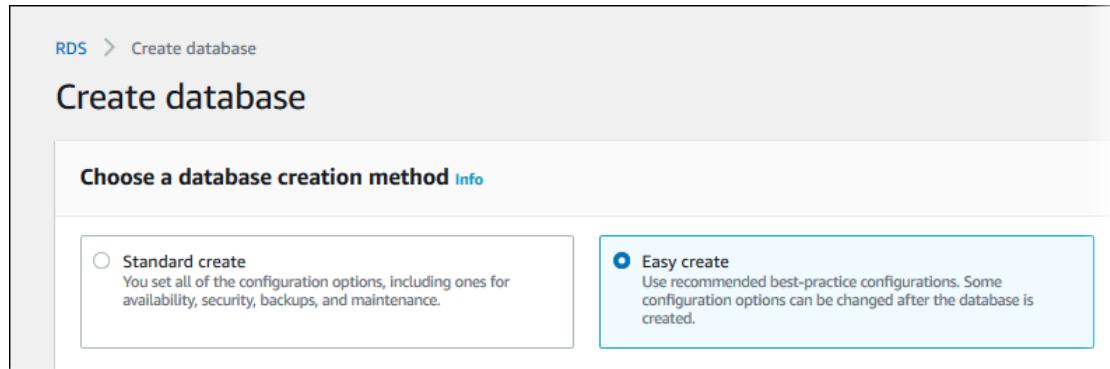

In this example, you use **Easy create** to create a DB instance running the MySQL database engine with a db.t2.micro DB instance class.

Note

For information about creating DB instances with **Standard create**, see [Creating an Amazon RDS DB instance \(p. 230\)](#).

To create a MySQL DB instance with Easy create

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.

5. In **Configuration**, choose **MySQL**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier**, enter a name for the DB instance, or leave the default name.
8. For **Master username**, enter a name for the master user, or leave the default name.

The **Create database** page should look similar to the following image.

Create database

Choose a database creation method [Info](#)

Standard create
You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy create
Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

Configuration

Engine type [Info](#)

Amazon Aurora 

MySQL

PostgreSQL 

Oracle 

Microsoft SQL Server 

DB instance size

Production
db.r6g.xlarge
4 vCPUs
32 GiB RAM
500 GiB

Dev/Test
db.r6g.large
2 vCPUs
16 GiB RAM
100 GiB

Free tier
db.t2.micro
1 vCPUs
1 GiB RAM
20 GiB

DB instance identifier
Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.

database-1

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Master username [Info](#)
Type a login ID for the master user of your DB instance.

admin

9. To use an automatically generated master password for the DB instance, make sure that the **Auto generate a password** box is selected.

To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

10. (Optional) Open **View default settings for Easy create**.

▼ View default settings for Easy create		
Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-6594f31c)	No
Option Group	default:mysql-8-0	Yes
Subnet Group	default	Yes
Automatic Backups	Enabled	Yes
VPC Security Group	sg-68184619	Yes
Publically Accessible	No	Yes
Database Port	3306	Yes
DB Instance Identifier	database-1	Yes
DB Engine Version	8.0.23	Yes
DB Parameter Group	default.mysql8.0	Yes
Performance Insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto Minor Version Upgrade Enabled	Yes
Delete Protection	Not Enabled	Yes

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after database creation.

- To change settings with **No** in that column, use **Standard create**.
- To change settings with **Yes** in that column, either use **Standard create**, or modify the DB instance after it is created to change the settings.

The following are important considerations for changing the default settings:

- In some cases, you might want your DB instance to use a specific virtual private cloud (VPC) based on the Amazon VPC service. Or you might require a specific subnet group or security group. If so,

use **Standard create** to specify these resources. You might have created these resources when you set up for Amazon RDS. For more information, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).

- If you want to be able to access the DB instance from a client outside of its VPC, use **Standard create** to set **Public access** to **Yes**.

If the DB instance should be private, leave **Public access** set to **No**.

11. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

You can use the user name and password that appears to connect to the DB instance as the master user.

Important

You can't view the master user password again. If you don't record it, you might have to change it.

If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

12. In the **Databases** list, choose the name of the new MySQL DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **Creating** until the DB instance is ready to use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

database-1		Modify	Actions ▾
Summary			
DB identifier database-1	CPU	Info 🕒 Creating	Class db.t2.micro
Role Instance	Current activity	Engine MySQL	Region & AZ -

Connecting to a database on a DB instance running the MySQL database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to a database on the DB instance. In this example, you connect to a database on a MySQL DB instance using MySQL monitor commands.

To connect to a database on a DB instance using MySQL monitor

1. Install a SQL client that you can use to connect to the DB instance.

You can connect to a MySQL DB instance by using tools such as the mysql command line utility. For more information on using the MySQL client, see [mysql - the MySQL command-line client](#)

in the MySQL documentation. One GUI-based application that you can use to connect is MySQL Workbench. For more information, see the [Download MySQL Workbench](#) page.

For more information on using MySQL, see the [MySQL documentation](#). For information about installing MySQL (including the MySQL client), see [Installing and upgrading MySQL](#).

If your DB instance is publicly accessible, you can install the SQL client outside of your VPC. If your DB instance is private, you typically install the SQL client on a resource inside your VPC, such as an Amazon EC2 instance.

2. Make sure that your DB instance is associated with a security group that provides access to it. For more information, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).

If you didn't specify the appropriate security group when you created the DB instance, you can modify the DB instance to change its security group. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

If your DB instance is publicly accessible, make sure its associated security group has inbound rules for the IP addresses that you want to access it. If your DB instance is private, make sure its associated security group has inbound rules for the security group of each resource to access it. An example is the security group for an Amazon EC2 instance.

3. Find the endpoint (DNS name) and port number for your DB instance.
 - a. Open the RDS console and then choose **Databases** to display a list of your DB instances.
 - b. Choose the MySQL DB instance name to display its details.
 - c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

The screenshot shows the Amazon RDS console interface. At the top, the navigation path is RDS > Databases > mydb. Below this, the database name "mydb" is displayed in a large font. A "Summary" section provides basic information: DB identifier (mydb), Role (Instance), CPU usage (2.33%), and Current activity (0 Connections). Below the summary, there are tabs for Connectivity & security, Monitoring, Logs & events, and Configuration. The Connectivity & security tab is selected. Under this tab, the "Endpoint & port" section is highlighted with a red oval. It shows the Endpoint as "mydb. [REDACTED].us-east-1.rds.amazonaws.com" and the Port as "3306". To the right of the endpoint, there is a vertical column of network-related information: Network (Available), us-east-1, VPC (vpc-6E), Subnet (default), and Default security group (not visible).

4. Connect to a database on a MySQL DB instance. For example, enter the following command at a command prompt on a client computer. By doing this, you connect to a database on a MySQL DB instance using the MySQL client.

Substitute the DNS name for your DB instance for `<endpoint>`. In addition, substitute the master user name that you used for `<mymasteruser>`, and provide the master password that you used when prompted for a password.

```
PROMPT> mysql -h <endpoint> -P 3306 -u <mymasteruser> -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.  
Your MySQL connection id is 9738  
Server version: 8.0.23 Source distribution  
  
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.  
  
mysql>
```

For more information about connecting to a MySQL DB instance, see [Connecting to a DB instance running the MySQL database engine \(p. 1318\)](#). If you can't connect to your DB instance, see [Can't connect to Amazon RDS DB instance \(p. 2141\)](#).

Deleting a DB instance

After you connect to and explore the sample DB instance that you created, delete it so you're no longer charged for it.

To delete a DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. For **Create final snapshot?**, choose **No**, and select the acknowledgment.
6. Choose **Delete**.

Creating an Oracle DB instance and connecting to a database on an Oracle DB instance

The basic building block of Amazon RDS is the DB instance. Your Amazon RDS DB instance is similar to your on-premises Oracle database.

Important

Before you can create or connect to a DB instance, make sure to complete the tasks in [Setting up for Amazon RDS \(p. 148\)](#).

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources that you use. You can delete these resources after you complete the tutorial if they are no longer needed.

In this topic, you create a sample Oracle DB instance and connect to it. Finally, you delete the sample DB instance.

Creating a sample Oracle DB instance

The DB instance is where you run your Oracle databases.

Note

RDS for Oracle supports a single-tenant architecture, where a pluggable database (PDB) resides in a multitenant container database (CDB). For more information, see [RDS for Oracle architecture \(p. 1480\)](#).

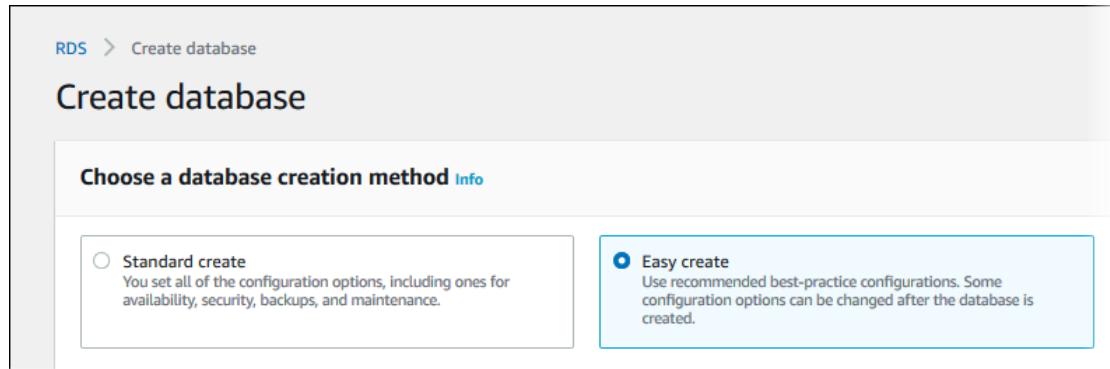

You can use **Easy create** to create a DB instance running Oracle with the AWS Management Console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. When you use **Standard create** instead of **Easy create**, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

In this example, you use **Easy create** to create a DB instance running the Oracle database engine with a db.m4.large DB instance class.

For information about creating DB instances with **Standard create**, see [Creating an Amazon RDS DB instance \(p. 230\)](#). If you want to use free tier, use **Standard create**.

To create an Oracle DB instance with Easy create enabled

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and ensure that **Easy create** is chosen.

5. In **Configuration**, choose **Oracle**.
6. For **DB instance size**, choose **Free tier**. If **Free tier** isn't available, choose **Dev/Test**.
7. For **DB instance identifier**, enter a name for the DB instance, or leave the default name of **database-1**.
8. For **Master username**, enter a name for the master user, or leave the default name.

The **Create database** page should look similar to the following image.

Create database

Choose a database creation method [Info](#)

Standard create

You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy create

Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

DB instance identifier

Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.

database-1

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Master username [Info](#)

Type a login ID for the master user of your DB instance.

9. To use an automatically generated master password for the DB instance, make sure that the **Auto generate a password** box is selected.

To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

10. (Optional) Open **View default settings for Easy create**.

▼ View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use [Standard Create](#).

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-2aed394c)	No
Option Group	default:oracle-se2-19	Yes
Subnet Group	default	Yes
Automatic Backups	Enabled	Yes
VPC Security Group	sg-0b4ff871	Yes
Publically Accessible	No	Yes
Database Port	1521	Yes
DB Instance Identifier	database-1	Yes
DB Engine Version	19.0.0.0.ru-2021-04.rur-2021-04.r1	Yes
DB Parameter Group	default.oracle-se2-19	Yes
Performance Insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto Minor Version Upgrade Enabled	Yes
Delete Protection	Not Enabled	Yes

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after database creation.

- To change settings with **No** in that column, use [Standard create](#).
- To change settings with **Yes** in that column, either use [Standard create](#), or modify the DB instance after it is created to change the settings.

The following are important considerations for changing the default settings:

- In some cases, you might want your DB instance to use a specific virtual private cloud (VPC) based on the Amazon VPC service. Or you might require a specific subnet group or security group. If so, use [Standard create](#) to specify these resources. You might have created these resources when you set up for Amazon RDS. For more information, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).

- If you want to be able to access the DB instance from a client outside of its VPC, use **Standard create** to set **Public access** to **Yes**.

If the DB instance should be private, leave **Public access** set to **No**.

- If you want to use free tier, use **Standard create** to set the Oracle version lower than version 12.2, and then choose **Free tier** in **Templates**.

11. Choose **Create database**.

If you used an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it.

If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

12. For **Databases**, choose the name of the new Oracle DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **Creating** until the DB instance is ready to use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

Connecting to your sample Oracle DB instance

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the DB instance. In this procedure, you connect to your sample DB instance by using the Oracle sqlplus command line utility. To download a standalone version of this utility, see [SQL*Plus User's Guide and Reference](#).

To connect to a DB instance using SQL*Plus

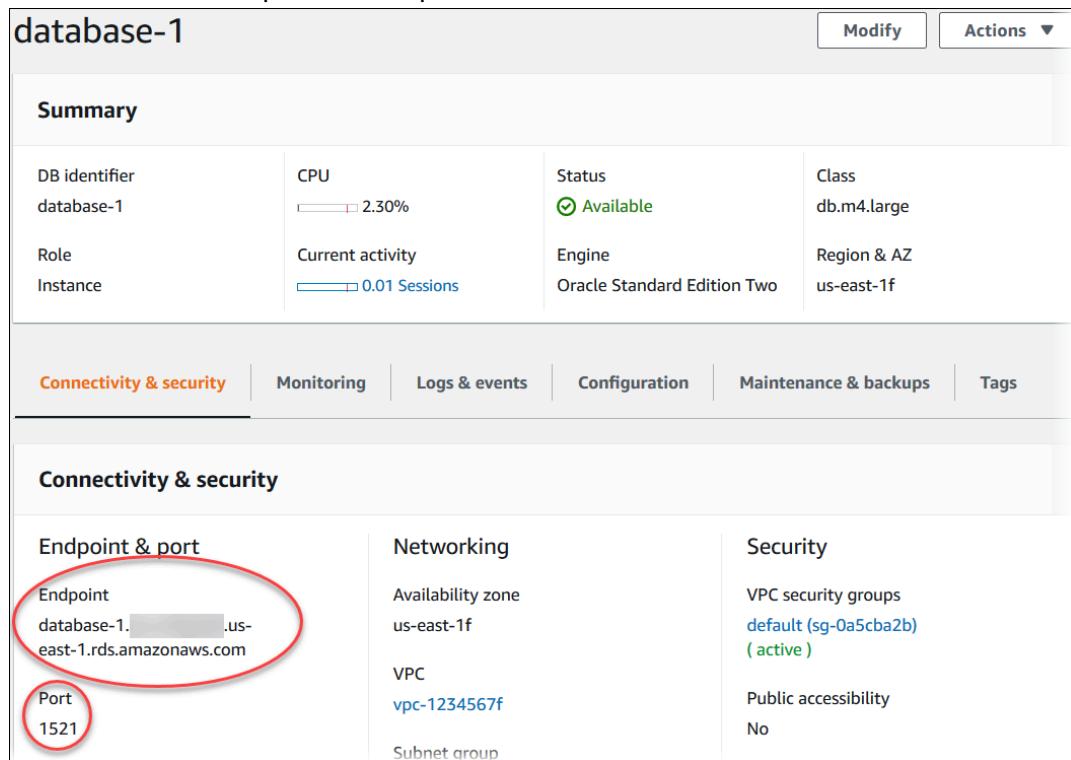

1. Make sure your DB instance is associated with a security group that provides access to it. For more information, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).

If you didn't specify the appropriate security group when you created the DB instance, you can modify the DB instance to change its security group. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

If your DB instance is publicly accessible, make sure its associated security group has inbound rules for the IP addresses that you want to access it. If your DB instance is private, make sure its associated security group has inbound rules for the security group of each resource to access it. An example is the security group for an Amazon EC2 instance.

2. Find the endpoint (DNS name) and port number for your DB instance.
 - a. Open the RDS console and then choose **Databases** to display a list of your DB instances.
 - b. Choose the Oracle DB instance name to display its details.
 - c. On the **Connectivity & security** tab, copy the following pieces of information:
 - Endpoint
 - Port

You need both the endpoint and the port number to connect to the DB instance.

Summary			
DB identifier	CPU	Status	Class
database-1	<div style="width: 20%;">2.30%</div>	Available	db.m4.large
Role	Current activity	Engine	Region & AZ
Instance	<div style="width: 10%;">0.01 Sessions</div>	Oracle Standard Edition Two	us-east-1f
Connectivity & security		Monitoring	Logs & events
Configuration		Maintenance & backups	Tags
Connectivity & security			
Endpoint & port Endpoint database-1...us-east-1.rds.amazonaws.com		Networking Availability zone us-east-1f	
Port 1521		Security VPC security groups default (sg-0a5cba2b) (active)	
		Public accessibility No	

- d. On the **Configuration** tab, copy the following pieces of information:

- DB name (not the DB instance ID)
- Master user name

You need both the DB name and the master user name to connect to the DB instance.

3. Enter the following command on one line at a command prompt to connect to your DB instance by using the sqlplus utility. Use the following values:
 - For **dbuser**, enter the name of the master user that you copied in the preceding steps.

- For HOST=*endpoint*, enter the endpoint that you copied in the preceding steps.
- For PORT=*portnum*, enter the port number that you copied in the preceding steps.
- For SID=*DB_NAME*, enter the Oracle database name (not the instance name) that you copied in the preceding steps.

```
sqlplus 'dbuser@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)(PORT=portnum))(CONNECT_DATA=(SID=DB_NAME)))'
```

You should see output similar to the following.

```
SQL*Plus: Release 11.1.0.7.0 - Production on Wed May 25 15:13:59 2011  
SQL>
```

For more information about connecting to an Oracle DB instance, see [Connecting to your Oracle DB instance \(p. 1488\)](#). For information on connection issues, see [Can't connect to Amazon RDS DB instance \(p. 2141\)](#).

Deleting your sample DB instance

After you explore the sample DB instance that you created, delete it so that you're no longer charged for it.

To delete a DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. For **Create final snapshot?**, choose **No**, and choose the acknowledgment.
6. Choose **Delete**.

Creating a PostgreSQL DB instance and connecting to a database on a PostgreSQL DB instance

The easiest way to create a DB instance is to use the AWS Management Console. After you have created the DB instance, you can use standard SQL client utilities to connect to the DB instance, such as the pgAdmin utility. In this example, you create a DB instance running the PostgreSQL database engine called database-1, with a db.r6g.large DB instance class and 100 gibibytes (GiB) of storage.

Important

Before you can create or connect to a DB instance, make sure to complete the tasks in [Setting up for Amazon RDS \(p. 148\)](#).

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources that you use. You can delete these resources after you complete the tutorial if they are no longer needed.

Contents

- [Connecting to a PostgreSQL DB instance \(p. 191\)](#)
 - [Using pgAdmin to connect to a PostgreSQL DB instance \(p. 192\)](#)
 - [Using psql to connect to a PostgreSQL DB instance \(p. 197\)](#)
- [Deleting a DB instance \(p. 197\)](#)

Creating a PostgreSQL DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your PostgreSQL databases.

You can use **Easy create** to create a DB instance running PostgreSQL with the AWS Management Console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. When you use **Standard create** instead of **Easy create**, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

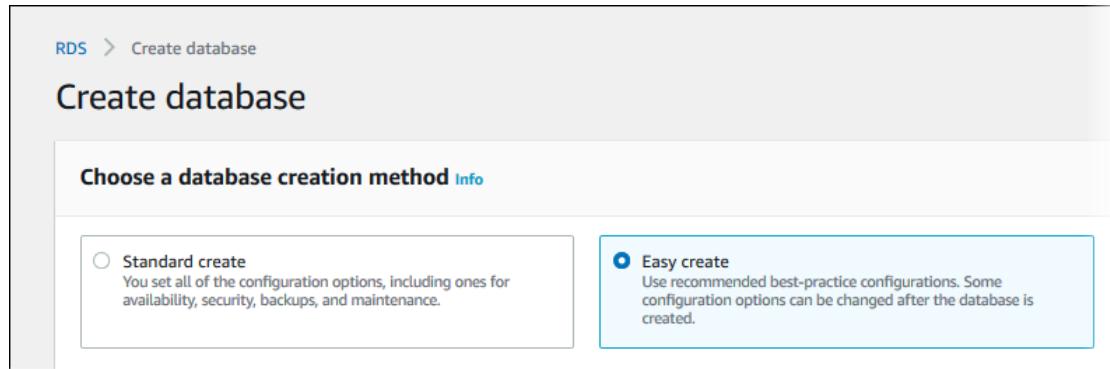

In this example, you use **Easy create** to create a DB instance running the PostgreSQL database engine with a db.r6g.large DB instance class.

Note

For information about creating DB instances with **Standard create**, see [Creating an Amazon RDS DB instance \(p. 230\)](#). If you want to use free tier, use **Standard create**.

To create a PostgreSQL DB instance with Easy create

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.

5. In **Configuration**, choose **PostgreSQL**.
6. For **DB instance size**, choose **Dev/Test**.
7. For **DB instance identifier**, enter a name for the DB instance, or leave the default name.
8. For **Master username**, enter a name for the master user, or leave the default name (**postgres**).

The **Create database** page should look similar to the following image.

Create database

Choose a database creation method Info

Standard create

You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy create

Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

Configuration

Engine type Info

Amazon Aurora

MySQL

MariaDB

PostgreSQL

Oracle

Microsoft SQL Server

DB instance size

Production

db.r6g.xlarge
4 vCPUs
32 GiB RAM
500 GiB

Dev/Test

db.r6g.large
2 vCPUs
16 GiB RAM
100 GiB

DB instance identifier

Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.

database-1

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Master username Info

Type a login ID for the master user of your DB instance.

9. To use an automatically generated master password for the DB instance, make sure that the **Auto generate a password** box is selected.

To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

10. (Optional) Open **View default settings for Easy create**.

▼ View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use [Standard Create](#).

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-2aed394c)	No
Option Group	default:postgres-13	No
Subnet Group	default	Yes
Automatic Backups	Enabled	Yes
VPC Security Group	sg-0b4ff871	Yes
Publically Accessible	No	Yes
Database Port	5432	Yes
DB Instance Identifier	database-1	Yes
DB Engine Version	13.3	Yes
DB Parameter Group	default.postgres13	Yes
Performance Insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto Minor Version Upgrade Enabled	Yes
Delete Protection	Not Enabled	Yes

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after database creation.

- To change settings with **No** in that column, use **Standard create**.
- To change settings with **Yes** in that column, either use **Standard create**, or modify the DB instance after it is created to change the settings.

The following are important considerations for changing the default settings:

- In some cases, you might want your DB instance to use a specific virtual private cloud (VPC) based on the Amazon VPC service. Or you might require a specific subnet group or security group. If so, use **Standard create** to specify these resources. You might have created these resources when you set up for Amazon RDS. For more information, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).

- If you want to be able to access the DB instance from a client outside of its VPC, use **Standard create** to set **Public access** to **Yes**.

If the DB instance should be private, leave **Public access** set to **No**.

- If you want to use free tier, use **Standard create** to set the PostgreSQL version lower than version 13, and then choose **Free tier** in **Templates**.

11. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it.

If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

12. For **Databases**, choose the name of the new PostgreSQL DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **Creating** until the DB instance is ready to use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

database-1				Modify	Actions ▾
Summary					
DB identifier	CPU	Status	Class		
database-1	-	Creating	db.r6g.large		
Role	Current activity	Engine	Region & AZ		
Instance	-1 Sessions	PostgreSQL	-		

[Connectivity & security](#) [Monitoring](#) [Logs & events](#) [Configuration](#) [Maintenance & backups](#)

Connecting to a PostgreSQL DB instance

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the instance. Following, you can find two ways to connect to a PostgreSQL DB instance. The first example uses pgAdmin, a popular open-source administration and development tool for PostgreSQL. You can download and use pgAdmin without having a local instance of PostgreSQL on your client computer. The second example uses psql, a command line utility that is part of a PostgreSQL installation. To use psql, make sure that you have PostgreSQL or the psql client installed on your client computer.

Before you try connecting to the DB instance, make sure that the DB instance is associated with a security group that provides access to it. For more information, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).

In some cases, you might have difficulty connecting to the DB instance. If so, the problem is most often with the access rules that you set up. These reside in the security group that you assigned to the DB instance. If you didn't specify the appropriate security group when you created the DB instance, you can modify the DB instance to change its security group. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

If your DB instance is publicly accessible, make sure its associated security group has inbound rules for the IP addresses that you want to access it. If your DB instance is private, make sure its associated security group has inbound rules for the security group of each resource to access it. An example is the security group for an Amazon EC2 instance.

For more information about connecting to a PostgreSQL DB instance, see [Connecting to a DB instance running the PostgreSQL database engine \(p. 1809\)](#). If you can't connect to your DB instance, see [Troubleshooting connections to your RDS for PostgreSQL instance \(p. 1814\)](#).

Topics

- [Using pgAdmin to connect to a PostgreSQL DB instance \(p. 192\)](#)
- [Using psql to connect to a PostgreSQL DB instance \(p. 197\)](#)

Using pgAdmin to connect to a PostgreSQL DB instance

To connect to a PostgreSQL DB instance using pgAdmin

1. Find the endpoint (DNS name) and port number for your DB instance.
 - a. Open the RDS console and then choose **Databases** to display a list of your DB instances.
 - b. Choose the PostgreSQL DB instance name to display its details.
 - c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

The screenshot shows the 'Summary' tab for a PostgreSQL DB instance named 'database-1'. The 'DB identifier' is listed as 'database-1'. Under the 'Role' section, 'Instance' is highlighted in orange. Below the summary, there are three tabs: 'Connectivity & security' (which is active and highlighted in red), 'Monitoring', and 'Logs & events'. The 'Connectivity & security' section displays the endpoint information. A red oval encircles the 'Endpoint' field ('database-1.us-west-1.rds.amazonaws.com') and the 'Port' field ('5432').

database-1

Summary

DB identifier
database-1

Role
Instance

Connectivity & security Monitoring Logs & events

Connectivity & security

Endpoint
database-1.us-west-1.rds.amazonaws.com

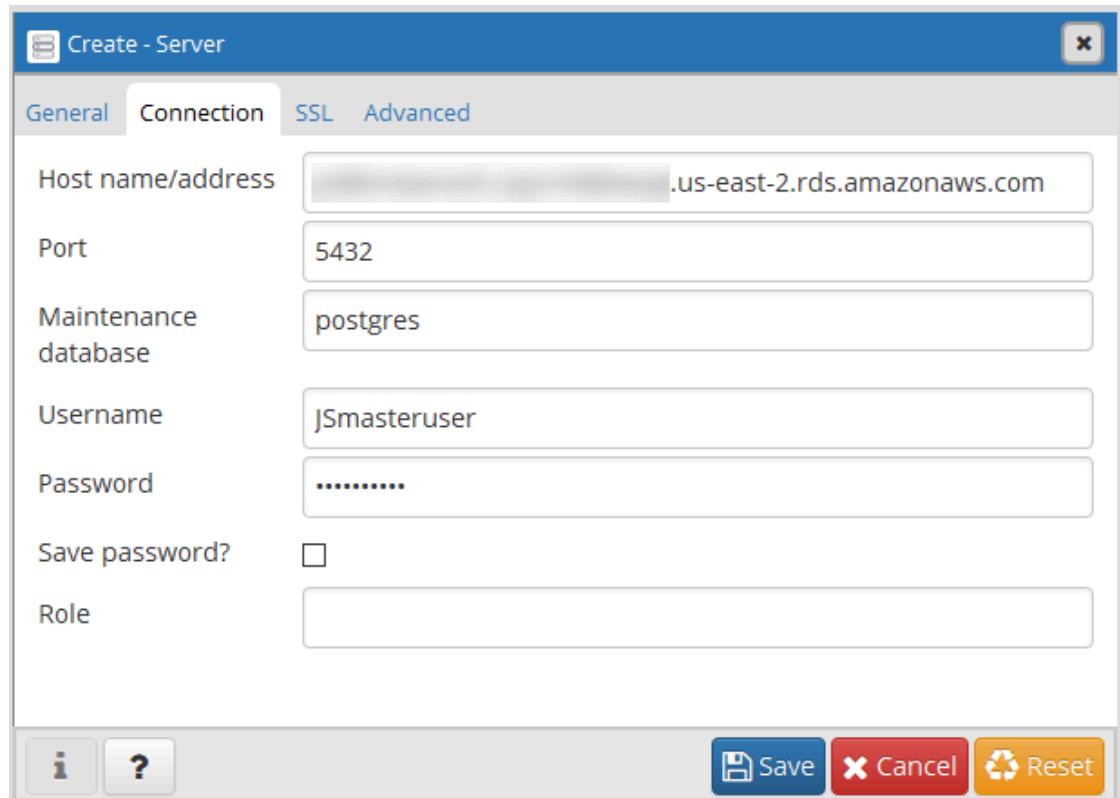

Port
5432

- d. On the **Configuration** tab, note the DB name. You don't need this to connect using pgAdmin, but you do need it to connect using psql.

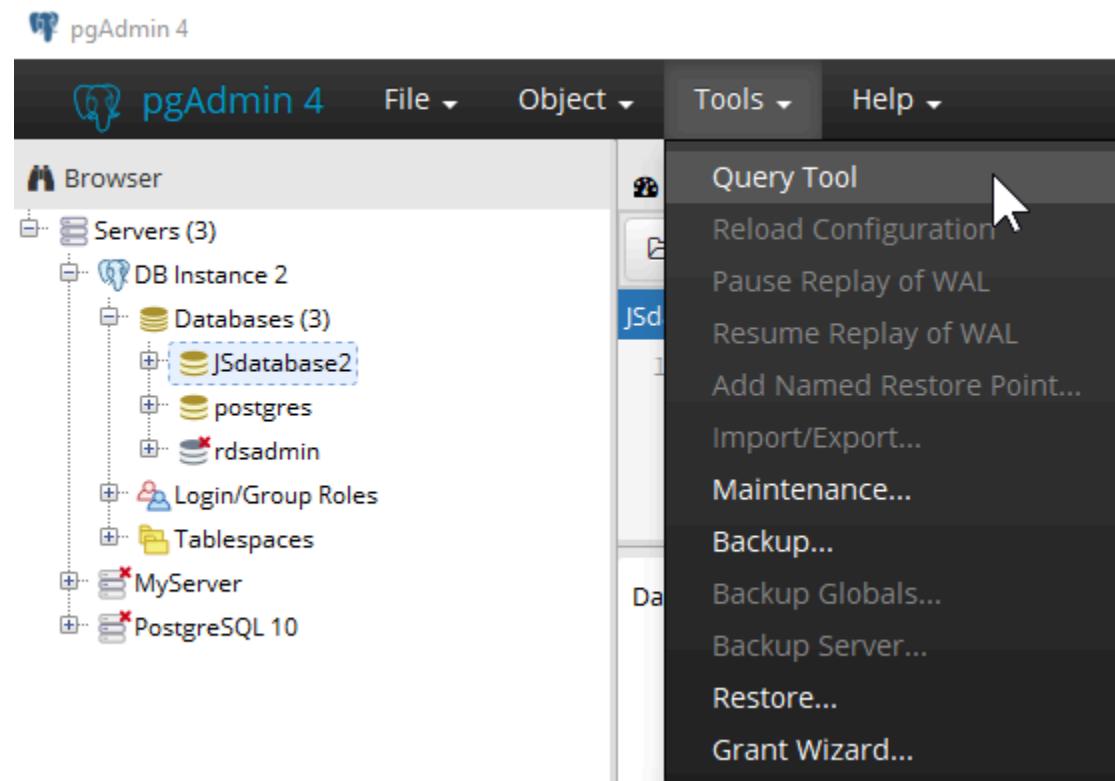

Connectivity & security	Monitoring	Logs & events	Configuration
Instance			
Configuration	Instance class	Storage	
DB instance ID	Instance class	Encryption	
database-1	db.m5.large	Enabled	
Engine version	vCPU	AWS KMS key	
13.4	2	aws/rds	
DB name	RAM	Storage type	
labdb	8 GB	General Purpose	

2. Install pgAdmin from <https://www.pgadmin.org/>. You can download and use pgAdmin without having a local instance of PostgreSQL on your client computer.
3. Launch the pgAdmin application on your client computer.
4. Choose **Add Server** from the **File** menu.
5. In the **New Server Registration** dialog box, enter the DB instance endpoint (for example, database-1.123456789012.us-west-1.rds.amazonaws.com) in the **Host** box. Don't include the colon or port number as shown on the Amazon RDS console (database-1.c6c8dntfzzhgv0.us-west-1.rds.amazonaws.com:5432).

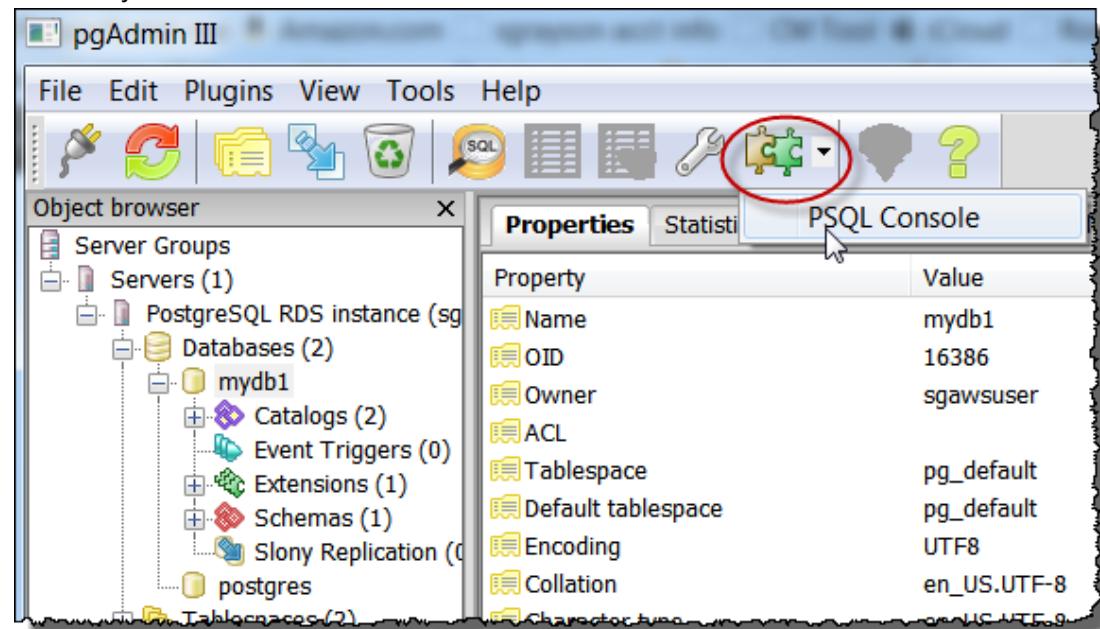

Enter the port you assigned to the DB instance for **Port**. Enter the user name and user password that you entered when you created the DB instance for **Username** and **Password**.

6. Choose **OK**.
7. In the Object browser, expand **Server Groups**. Choose the server (the DB instance) you created, and then choose the database name.

8. Choose the plugin icon and choose **PSQL Console**. The psql command window opens for the default database you created.

9. Use the command window to enter SQL or psql commands. Enter \q to close the window.

Using psql to connect to a PostgreSQL DB instance

If your client computer has PostgreSQL installed, you can use a local instance of psql to connect to a PostgreSQL DB instance. To connect to your PostgreSQL DB instance using psql, you provide host information, port number, access credentials, and the database name. You can obtain these details by following the first step in the procedure for [Using pgAdmin to connect to a PostgreSQL DB instance \(p. 192\)](#)

The following format is used to connect to a PostgreSQL DB instance on Amazon RDS.

```
psql --host=DB_instance_endpoint --port=port --username=master_user_name --password --  
dbname=database_name
```

For example, the following command connects to a database called mypgdb on a PostgreSQL DB instance called mypostgresql using fictitious credentials.

```
psql --host=database-1.123456789012.us-west-1.rds.amazonaws.com --port=5432 --  
username=awsuser --password --dbname=postgres
```

Deleting a DB instance

After you connect to the sample DB instance that you created, delete it so you're no longer charged for it.

To delete a DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. For **Create final snapshot?**, choose **No**, and select the acknowledgment.
6. Choose **Delete**.

Tutorial: Create a web server and an Amazon RDS DB instance

This tutorial helps you install an Apache web server with PHP and create a MySQL database. The web server runs on an Amazon EC2 instance using Amazon Linux, and the MySQL database is a MySQL DB instance. Both the Amazon EC2 instance and the DB instance run in a virtual private cloud (VPC) based on the Amazon VPC service.

Important

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

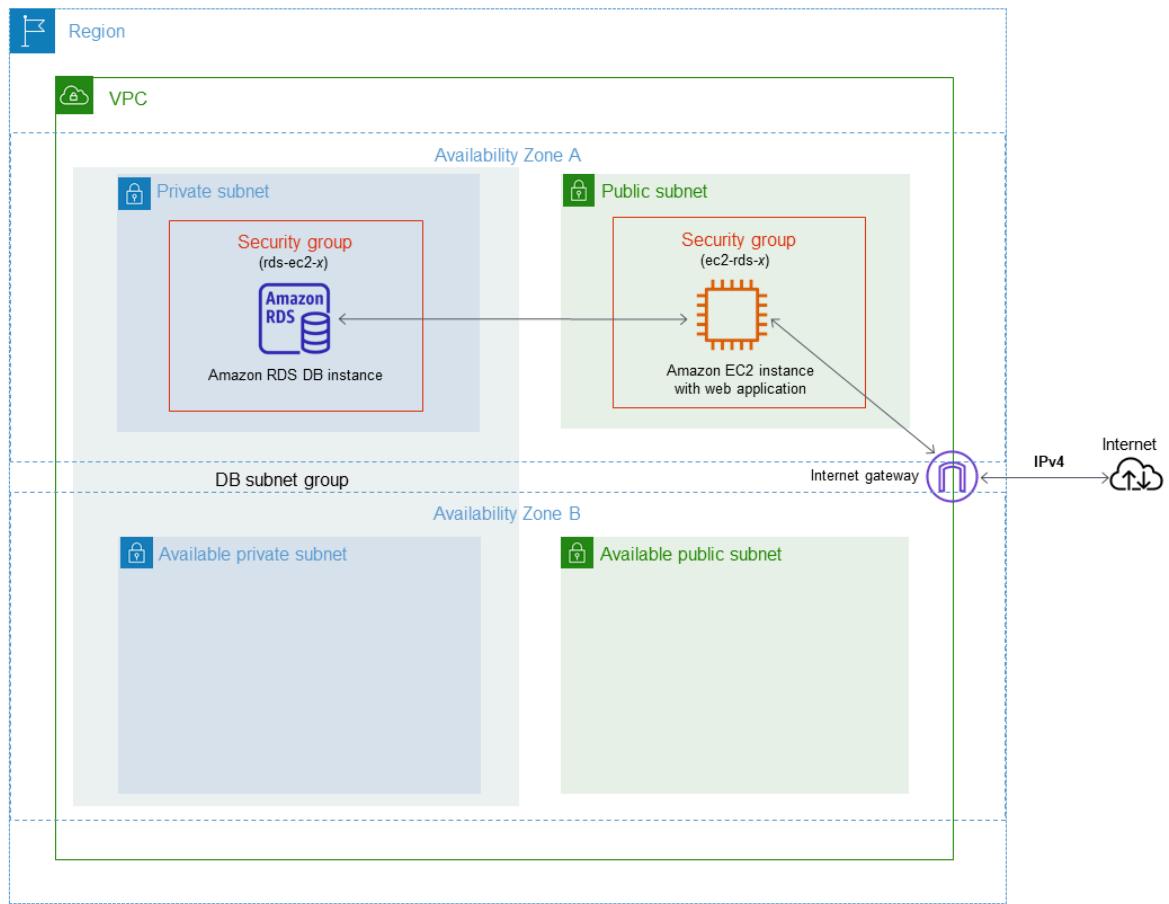

Note

This tutorial works with Amazon Linux and might not work for other versions of Linux such as Ubuntu.

In the tutorial that follows, you create an EC2 instance that uses the default VPC, subnets, and security group for your AWS account. This tutorial shows you how to create the DB instance and automatically set up connectivity with the EC2 instance that you created. The tutorial then shows you how to install the web server on the EC2 instance. You connect your web server to your DB instance in the VPC using the DB instance endpoint.

1. [Launch an EC2 instance \(p. 199\)](#)
2. [Create a DB instance \(p. 203\)](#)
3. [Install a web server on your EC2 instance \(p. 207\)](#)

The following diagram shows the configuration when the tutorial is complete.

Note

This tutorial uses the default VPC for your AWS account and automatically sets up connectivity between your EC2 instance and DB instance. If you would rather configure a new VPC for this scenario instead, complete the tasks in [Tutorial: Create a VPC for use with a DB instance \(IPv4 only\) \(p. 2120\)](#).

Launch an EC2 instance

Create an Amazon EC2 instance in the public subnet of your VPC.

To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region where you want to create the EC2 instance.
3. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown following.

Resources

You are using the following Amazon EC2 resources in the US West (Oregon) Region:

Instances (running)	3	Dedicated Hosts	0
Instances	3	Key pairs	5
Placement groups	0	Security groups	10
Volumes	3		

i Easily size, configure, and deploy Microsoft SQL Server Always On availability groups on AWS using [Learn more](#)

Launch instance

To get started, launch an Amazon EC2 instance, which is a virtual server in the cloud.

Launch instance ▾ [Migrate a server ↗](#)

Note: Your instances will launch in the US West (Oregon) Region

Service health

Region
US West (Oregon)

Zones

4. Make sure you have opted into the new launch experience.
5. Under **Name and tags**, for **Name**, enter **tutorial-ec2-instance-web-server**.
6. Under **Application and OS Images (Amazon Machine Image)**, choose **Amazon Linux**, and then choose the **Amazon Linux 2 AMI**. Keep the defaults for the other choices.

▼ Application and OS Images (Amazon Machine Image) [Info](#)

An AMI is a template that contains the software configuration (operating system, application server, and applications) required to launch your instance. Search or Browse for AMIs if you don't see what you are looking for below

Search our full catalog including 1000s of application and OS images

Recents Quick Start

Amazon Linux Ubuntu Windows Red Hat SUSE Linux

aws ubuntu® Microsoft Red Hat SUSE

Amazon Machine Image (AMI)

Amazon Linux 2 AMI (HVM) - Kernel 5.10, SSD Volume Type Free tier eligible

ami-098e42ae54c764c35 (64-bit (x86)) / ami-08e93a9522bbe6df6 (64-bit (Arm))
Virtualization: hvm ENA enabled: true Root device type: ebs

Description
Amazon Linux 2 Kernel 5.10 AMI 2.0.20220606.1 x86_64 HVM gp2

Architecture AMI ID

64-bit (x86) ami-098e42ae54c764c35

7. Under **Instance type**, choose **t2.micro**.
8. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see [Create a key pair](#) in the *Amazon EC2 User Guide for Linux Instances*.

9. Under **Network settings**, set these values and keep the other values as their defaults:
 - For **Allow SSH traffic from**, choose the source of SSH connections to the EC2 instance.

You can choose **My IP** if the displayed IP address is correct for SSH connections.

Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at <https://checkip.amazonaws.com>. An example of an IP address is 203.0.113.25/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

Warning

If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

- Turn on **Allow HTTPs traffic from the internet**.
- Turn on **Allow HTTP traffic from the internet**.

▼ **Network settings** [Get guidance](#) [Edit](#)

Network [Info](#)
vpc-2aed394c

Subnet [Info](#)
No preference (Default subnet in any availability zone)

Auto-assign public IP [Info](#)
Enable

Firewall (security groups) [Info](#)
A security group is a set of firewall rules that control the traffic for your instance. Add rules to allow specific traffic to reach your instance.

[Create security group](#) [Select existing security group](#)

We'll create a new security group called '**launch-wizard-1**' with the following rules:

Allow SSH traffic from
Helps you connect to your instance My IP ▾

Allow HTTPs traffic from the internet
To set up an endpoint, for example when creating a web server

Allow HTTP traffic from the internet
To set up an endpoint, for example when creating a web server

⚠ Rules with source of `0.0.0.0/0` allow all IP addresses to access your instance. We recommend setting security group rules to allow access from known IP addresses only. X

10. Leave the default values for the remaining sections.
11. Review a summary of your instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.
12. On the **Launch Status** page, shown following, note the identifier for your new EC2 instance, for example: `i-03a6ad47e97ba9dc5`.

The screenshot shows a success message: "Successfully initiated launch of instance (i-03a6ad47e97ba9dc5)". The instance ID is highlighted with a red oval. Below the message is a "Launch log" link.

Next Steps

Get notified of estimated charges
Create billing alerts to get an email notification when estimated charges on your AWS bill exceed an amount you define (for example, if you exceed the free usage tier)

How to connect to your instance
Your instance is launching and it might be a few minutes until it is in the running state, when it will be ready for you to use
Click View Instances to monitor your instance's status. Once your instance is in the 'running' state, you can connect to it from the Instances screen. Find out [how to connect to your instance](#)

[View more resources to get you started](#)

[View all instances](#)

13. Choose **View all instances** to find your instance.
14. Wait until **Instance state** for your instance is **Running** before continuing.
15. Complete [Create a DB instance \(p. 203\)](#).

Create a DB instance

Create an Amazon RDS for MySQL DB instance that maintains the data used by a web application.

To create a MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, check the AWS Region. It should be the same as the one where you created your EC2 instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, shown following, make sure that the **Standard create** option is chosen, and then choose **MySQL**.

RDS > Create database

Create database

Choose a database creation method [Info](#)

Standard create
You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy create
Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

Engine options

Known issues/limitations
Review the [Known issues/limitations](#) to learn about potential compatibility issues with specific database versions.

Version

6. In the **Templates** section, choose **Free tier**.
7. In the **Availability and durability** section, keep the defaults.
8. In the **Settings** section, set these values:
 - **DB instance identifier** – Type **tutorial-db-instance**.
 - **Master username** – Type **tutorial_user**.
 - **Auto generate a password** – Leave the option turned off.
 - **Master password** – Type a password.
 - **Confirm password** – Retype the password.

Settings

DB instance identifier [Info](#)
Type a name for your DB instance. The name must be unique cross all DB instances owned by your AWS account in the current AWS Region.

tutorial-db-instance

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens (1 to 15 for SQL Server). First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Credentials Settings

Master username [Info](#)
Type a login ID for the master user of your DB instance.

tutorial_user

1 to 16 alphanumeric characters. First character must be a letter

Auto generate a password
Amazon RDS can generate a password for you, or you can specify your own password

Master password [Info](#)

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), "(double quote) and @ (at sign).

Confirm password [Info](#)

9. In the **Instance configuration** section, set these values:

- **Burstable classes (includes t classes)**
- **db.t3.micro**

Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class [Info](#)

Standard classes (includes m classes)
 Memory optimized classes (includes r and x classes)
 Burstable classes (includes t classes)

db.t3.micro
2 vCPUs 1 GiB RAM Network: 2,085 Mbps ▾

Include previous generation classes

10. In the **Storage** section, keep the defaults.

11. In the **Connectivity** section, set these values and keep the other values as their defaults:

- For **Compute resource**, choose **Connect to an EC2 compute resource**.
- For **EC2 instance**, choose the EC2 instance you created previously, such as **tutorial-ec2-instance-web-server**.

The screenshot shows the 'Connectivity' configuration section. It includes two radio button options: 'Don't connect to an EC2 compute resource' (unchecked) and 'Connect to an EC2 compute resource' (checked). A note below explains that selecting 'Connect to an EC2 compute resource' will automatically set up connectivity settings. Below this is the 'EC2 Instance' section, which lists the selected EC2 instance as 'tutorial-ec2-instance-web-server'. A callout box provides a note about VPC settings.

Connectivity Info

Compute resource
Choose whether to set up a connection to a compute resource for this database. Setting up a connection will automatically change connectivity settings so that the compute resource can connect to this database.

Don't connect to an EC2 compute resource
Don't set up a connection to a compute resource for this database. You can manually set up a connection to a compute resource later.

Connect to an EC2 compute resource
Set up a connection to an EC2 compute resource for this database.

EC2 Instance Info
Choose the EC2 instance to add as the compute resource for this database. A VPC security group is added to this EC2 instance. A VPC security group is also added to the database with an inbound rule that allows the EC2 instance to access the database.

tutorial-ec2-instance-web-server ▾

i Some VPC settings can't be changed when a compute resource is added
Adding an EC2 compute resource automatically selects the VPC, DB subnet group, and public access settings for this database. To allow the EC2 instance to access the database, a VPC security group rds-ec2-X is added to the database and another called ec2-rds-X to the EC2 instance. You can remove the new security group for the database only by removing the compute resource.

12. In the **Database authentication** section, make sure **Password authentication** is selected.
13. Open the **Additional configuration** section, and enter **sample** for **Initial database name**. Keep the default settings for the other options.
14. To create your MySQL DB instance, choose **Create database**.

Your new DB instance appears in the **Databases** list with the status **Creating**.

15. Wait for the **Status** of your new DB instance to show as **Available**. Then choose the DB instance name to show its details.
16. In the **Connectivity & security** section, view the **Endpoint** and **Port** of the DB instance.

RDS > Databases > tutorial-db-instance

tutorial-db-instance

Summary

DB identifier	tutorial-db-instance	CPU	3.10%
Role	Instance	Current activity	0 Connections

Connectivity & security Monitoring Logs & events Configuration Maintenance

Connectivity & security

Endpoint & port	Networking
Endpoint	Availability Zone
tutorial-db-instance.[REDACTED].west-2.rds.amazonaws.com	us-west-2a
Port	VPC
3306	tutorial-vpc (vpc-04badc20a546242e6)
	Subnet group

Note the endpoint and port for your DB instance. You use this information to connect your web server to your DB instance.

17. Complete [Install a web server on your EC2 instance \(p. 207\)](#).

Install a web server on your EC2 instance

Install a web server on the EC2 instance you created in [Launch an EC2 instance \(p. 199\)](#). The web server connects to the Amazon RDS DB instance that you created in [Create a DB instance \(p. 203\)](#).

Install an Apache web server with PHP and MariaDB

Connect to your EC2 instance and install the web server.

To connect to your EC2 instance and install the Apache web server with PHP

1. Connect to the EC2 instance that you created earlier by following the steps in [Connect to your Linux instance](#).
2. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

Note

The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

```
sudo yum update -y
```

3. After the updates complete, install the PHP software using the `amazon-linux-extras install` command. This command installs multiple software packages and related dependencies at the same time.

```
sudo amazon-linux-extras install php8.0 mariadb10.5
```

If you receive an error stating `sudo: amazon-linux-extras: command not found`, your instance wasn't launched with an Amazon Linux 2 AMI. You might be using the Amazon Linux AMI instead. You can view your version of Amazon Linux using the following command.

```
cat /etc/system-release
```

For more information, see [Updating instance software](#).

4. Install the Apache web server.

```
sudo yum install -y httpd
```

5. Start the web server with the command shown following.

```
sudo systemctl start httpd
```

You can test that your web server is properly installed and started. To do this, enter the public Domain Name System (DNS) name of your EC2 instance in the address bar of a web browser, for example: `http://ec2-42-8-168-21.us-west-1.compute.amazonaws.com`. If your web server is running, then you see the Apache test page.

If you don't see the Apache test page, check your inbound rules for the VPC security group that you created in [Tutorial: Create a VPC for use with a DB instance \(IPv4 only\) \(p. 2120\)](#). Make sure that your inbound rules include one allowing HTTP (port 80) access for the IP address to connect to the web server.

Note

The Apache test page appears only when there is no content in the document root directory, `/var/www/html`. After you add content to the document root directory, your content appears at the public DNS address of your EC2 instance. Before this point, it appears on the Apache test page.

6. Configure the web server to start with each system boot using the `systemctl` command.

```
sudo systemctl enable httpd
```

To allow ec2-user to manage files in the default root directory for your Apache web server, modify the ownership and permissions of the /var/www directory. There are many ways to accomplish this task. In this tutorial, you add ec2-user to the apache group, to give the apache group ownership of the /var/www directory and assign write permissions to the group.

To set file permissions for the Apache web server

1. Add the ec2-user user to the apache group.

```
sudo usermod -a -G apache ec2-user
```

2. Log out to refresh your permissions and include the new apache group.

```
exit
```

3. Log back in again and verify that the apache group exists with the groups command.

```
groups
```

Your output looks similar to the following:

```
ec2-user adm wheel apache systemd-journal
```

4. Change the group ownership of the /var/www directory and its contents to the apache group.

```
sudo chown -R ec2-user:apache /var/www
```

5. Change the directory permissions of /var/www and its subdirectories to add group write permissions and set the group ID on subdirectories created in the future.

```
sudo chmod 2775 /var/www
find /var/www -type d -exec sudo chmod 2775 {} \;
```

6. Recursively change the permissions for files in the /var/www directory and its subdirectories to add group write permissions.

```
find /var/www -type f -exec sudo chmod 0664 {} \;
```

Now, ec2-user (and any future members of the apache group) can add, delete, and edit files in the Apache document root. This makes it possible for you to add content, such as a static website or a PHP application.

Note

A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, much information is visible to eavesdroppers anywhere along the network pathway. This information includes the URLs that you visit, the content of webpages that you receive, and the contents (including passwords) of any HTML forms.

The best practice for securing your web server is to install support for HTTPS (HTTP Secure). This protocol protects your data with SSL/TLS encryption. For more information, see [Tutorial: Configure SSL/TLS with the Amazon Linux AMI](#) in the *Amazon EC2 User Guide*.

Connect your Apache web server to your DB instance

Next, you add content to your Apache web server that connects to your Amazon RDS DB instance.

To add content to the Apache web server that connects to your DB instance

1. While still connected to your EC2 instance, change the directory to /var/www and create a new subdirectory named inc.

```
cd /var/www
mkdir inc
cd inc
```

2. Create a new file in the inc directory named dbinfo.inc, and then edit the file by calling nano (or the editor of your choice).

```
>dbinfo.inc
nano dbinfo.inc
```

3. Add the following contents to the dbinfo.inc file. Here, *db_instance_endpoint* is your DB instance endpoint, without the port, and *master password* is the master password for your DB instance.

Note

We recommend placing the user name and password information in a folder that isn't part of the document root for your web server. Doing this reduces the possibility of your security information being exposed.

```
<?php

define('DB_SERVER', 'db_instance_endpoint');
define('DB_USERNAME', 'tutorial_user');
define('DB_PASSWORD', 'master password');
define('DB_DATABASE', 'sample');

?>
```

4. Save and close the dbinfo.inc file.
5. Change the directory to /var/www/html.

```
cd /var/www/html
```

6. Create a new file in the html directory named SamplePage.php, and then edit the file by calling nano (or the editor of your choice).

```
>SamplePage.php
nano SamplePage.php
```

7. Add the following contents to the SamplePage.php file:

```
<?php include "../inc/dbinfo.inc"; ?>
<html>
<body>
<h1>Sample page</h1>
<?php

/* Connect to MySQL and select the database. */
$connection = mysqli_connect(DB_SERVER, DB_USERNAME, DB_PASSWORD);

if (mysqli_connect_errno()) echo "Failed to connect to MySQL: " .
mysqli_connect_error();
```

```

$database = mysqli_select_db($connection, DB_DATABASE);

/* Ensure that the EMPLOYEES table exists. */
VerifyEmployeesTable($connection, DB_DATABASE);

/* If input fields are populated, add a row to the EMPLOYEES table. */
$employee_name = htmlentities($_POST['NAME']);
$employee_address = htmlentities($_POST['ADDRESS']);

if (strlen($employee_name) || strlen($employee_address)) {
    AddEmployee($connection, $employee_name, $employee_address);
}
?>

<!-- Input form -->
<form action=<?PHP echo $_SERVER['SCRIPT_NAME'] ?>" method="POST">
    <table border="0">
        <tr>
            <td>NAME</td>
            <td>ADDRESS</td>
        </tr>
        <tr>
            <td>
                <input type="text" name="NAME" maxlength="45" size="30" />
            </td>
            <td>
                <input type="text" name="ADDRESS" maxlength="90" size="60" />
            </td>
            <td>
                <input type="submit" value="Add Data" />
            </td>
        </tr>
    </table>
</form>

<!-- Display table data. -->
<table border="1" cellpadding="2" cellspacing="2">
    <tr>
        <td>ID</td>
        <td>NAME</td>
        <td>ADDRESS</td>
    </tr>
?>

<?php

$result = mysqli_query($connection, "SELECT * FROM EMPLOYEES");

while($query_data = mysqli_fetch_row($result)) {
    echo "<tr>";
    echo "<td>",$query_data[0], "</td>",
          "<td>",$query_data[1], "</td>",
          "<td>",$query_data[2], "</td>";
    echo "</tr>";
}
?>

</table>

<!-- Clean up. -->
<?php

    mysqli_free_result($result);
    mysqli_close($connection);

?>

```

```

</body>
</html>

<?php

/* Add an employee to the table. */
function AddEmployee($connection, $name, $address) {
    $n = mysqli_real_escape_string($connection, $name);
    $a = mysqli_real_escape_string($connection, $address);

    $query = "INSERT INTO EMPLOYEES (NAME, ADDRESS) VALUES ('$n', '$a');";

    if(!mysqli_query($connection, $query)) echo("<p>Error adding employee data.</p>");

}

/* Check whether the table exists and, if not, create it. */
function VerifyEmployeesTable($connection, $dbName) {
    if(!TableExists("EMPLOYEES", $connection, $dbName))
    {
        $query = "CREATE TABLE EMPLOYEES (
            ID int(11) UNSIGNED AUTO_INCREMENT PRIMARY KEY,
            NAME VARCHAR(45),
            ADDRESS VARCHAR(90)
        )";

        if(!mysqli_query($connection, $query)) echo("<p>Error creating table.</p>");

    }
}

/* Check for the existence of a table. */
function TableExists($tableName, $connection, $dbName) {
    $t = mysqli_real_escape_string($connection, $tableName);
    $d = mysqli_real_escape_string($connection, $dbName);

    $checktable = mysqli_query($connection,
        "SELECT TABLE_NAME FROM information_schema.TABLES WHERE TABLE_NAME = '$t' AND
        TABLE_SCHEMA = '$d'");

    if(mysqli_num_rows($checktable) > 0) return true;

    return false;
}
?>
```

8. Save and close the SamplePage.php file.
9. Verify that your web server successfully connects to your DB instance by opening a web browser and browsing to <http://EC2 instance endpoint>/SamplePage.php, for example: <http://ec2-55-122-41-31.us-west-2.compute.amazonaws.com>/SamplePage.php.

You can use SamplePage.php to add data to your DB instance. The data that you add is then displayed on the page. To verify that the data was inserted into the table, install MySQL client on the Amazon EC2 instance. Then connect to the DB instance and query the table.

For information about installing the MySQL client and connecting to a DB instance, see [Connecting to a DB instance running the MySQL database engine \(p. 1318\)](#).

To make sure that your DB instance is as secure as possible, verify that sources outside of the VPC can't connect to your DB instance.

After you have finished testing your web server and your database, you should delete your DB instance and your Amazon EC2 instance.

- To delete a DB instance, follow the instructions in [Deleting a DB instance \(p. 421\)](#). You don't need to create a final snapshot.
- To terminate an Amazon EC2 instance, follow the instruction in [Terminate your instance](#) in the *Amazon EC2 User Guide*.

Amazon RDS tutorials and sample code

The AWS documentation includes several tutorials that guide you through common Amazon RDS use cases. Many of these tutorials show you how to use Amazon RDS with other AWS services. In addition, you can access sample code in GitHub.

Note

You can find more tutorials at the [AWS Database Blog](#). For information about training, see [AWS Training and Certification](#).

Amazon RDS basic operational guidelines

The following are basic operational guidelines that everyone should follow when working with Amazon RDS. Note that the Amazon RDS Service Level Agreement requires that you follow these guidelines:

- Use metrics to monitor your memory, CPU, replica lag, and storage usage. You can set up Amazon CloudWatch to notify you when usage patterns change or when you approach the capacity of your deployment. This way, you can maintain system performance and availability.
- Scale up your DB instance when you are approaching storage capacity limits. You should have some buffer in storage and memory to accommodate unforeseen increases in demand from your applications.
- Enable automatic backups and set the backup window to occur during the daily low in write IOPS. That's when a backup is least disruptive to your database usage.
- If your database workload requires more I/O than you have provisioned, recovery after a failover or database failure will be slow. To increase the I/O capacity of a DB instance, do any or all of the following:
 - Migrate to a different DB instance class with high I/O capacity.
 - Convert from magnetic storage to either General Purpose or Provisioned IOPS storage, depending on how much of an increase you need. For information on available storage types, see [Amazon RDS storage types \(p. 64\)](#).

If you convert to Provisioned IOPS storage, make sure you also use a DB instance class that is optimized for Provisioned IOPS. For information on Provisioned IOPS, see [Provisioned IOPS SSD storage \(p. 66\)](#).

- If you are already using Provisioned IOPS storage, provision additional throughput capacity.
- If your client application is caching the Domain Name Service (DNS) data of your DB instances, set a time-to-live (TTL) value of less than 30 seconds. The underlying IP address of a DB instance can change after a failover. Caching the DNS data for an extended time can thus lead to connection failures. Your application might try to connect to an IP address that's no longer in service.
- Test failover for your DB instance to understand how long the process takes for your particular use case. Also test failover to ensure that the application that accesses your DB instance can automatically connect to the new DB instance after failover occurs.

DB instance RAM recommendations

An Amazon RDS performance best practice is to allocate enough RAM so that your *working set* resides almost completely in memory. The working set is the data and indexes that are frequently in use on your instance. The more you use the DB instance, the more the working set will grow.

To tell if your working set is almost all in memory, check the ReadIOPS metric (using Amazon CloudWatch) while the DB instance is under load. The value of ReadIOPS should be small and stable. In some cases, scaling up the DB instance class to a class with more RAM results in a dramatic drop in ReadIOPS. In these cases, your working set was not almost completely in memory. Continue to scale up until ReadIOPS no longer drops dramatically after a scaling operation, or ReadIOPS is reduced to a very small amount. For information on monitoring a DB instance's metrics, see [Viewing metrics in the Amazon RDS console \(p. 525\)](#).

Using Enhanced Monitoring to identify operating system issues

When Enhanced Monitoring is enabled, Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console. You can also consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information about Enhanced Monitoring, see [Monitoring OS metrics with Enhanced Monitoring \(p. 600\)](#).

Using metrics to identify performance issues

To identify performance issues caused by insufficient resources and other common bottlenecks, you can monitor the metrics available for your Amazon RDS DB instance.

Viewing performance metrics

You should monitor performance metrics on a regular basis to see the average, maximum, and minimum values for a variety of time ranges. If you do so, you can identify when performance is degraded. You can also set Amazon CloudWatch alarms for particular metric thresholds so you are alerted if they are reached.

To troubleshoot performance issues, it's important to understand the baseline performance of the system. When you set up a DB instance and run it with a typical workload, capture the average, maximum, and minimum values of all performance metrics. Do so at a number of different intervals (for example, one hour, 24 hours, one week, two weeks). This can give you an idea of what is normal. It helps to get comparisons for both peak and off-peak hours of operation. You can then use this information to identify when performance is dropping below standard levels.

If you use Multi-AZ DB clusters, monitor the time difference between the latest transaction on the writer DB instance and the latest applied transaction on a reader DB instance. This difference is called *replica lag*. For more information, see [Replica lag and Multi-AZ DB clusters \(p. 133\)](#).

To view performance metrics

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose a DB instance.
3. Choose **Monitoring**. The first eight performance metrics display. The metrics default to showing information for the current day.
4. Use the numbered buttons at top right to page through the additional metrics, or adjust the settings to see more metrics.
5. Choose a performance metric to adjust the time range in order to see data for other than the current day. You can change the **Statistic**, **Time Range**, and **Period** values to adjust the information displayed. For example, you might want to see the peak values for a metric for each day of the last two weeks. If so, set **Statistic** to **Maximum**, **Time Range** to **Last 2 Weeks**, and **Period** to **Day**.

Note

Changing the **Statistic**, **Time Range**, and **Period** values changes them for all metrics. The updated values persist for the remainder of your session or until you change them again.

You can also view performance metrics using the CLI or API. For more information, see [Viewing metrics in the Amazon RDS console \(p. 525\)](#).

To set a CloudWatch alarm

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose a DB instance.
3. Choose **Logs & events**.
4. In the **CloudWatch alarms** section, choose **Create alarm**.

Create alarm

You can use CloudWatch alarms to be notified automatically whenever metric data reaches a level you define.

Settings

[Refresh](#)

To edit an alarm, first choose whom to notify and then define when the notification should be sent.

5. For **Send notifications**, choose **Yes**, and for **Send notifications to**, choose **New email or SMS topic**.
6. For **Topic name**, enter a name for the notification, and for **With these recipients**, enter a comma-separated list of email addresses and phone numbers.
7. For **Metric**, choose the alarm statistic and metric to set.
8. For **Threshold**, specify whether the metric must be greater than, less than, or equal to the threshold, and specify the threshold value.
9. For **Evaluation period**, choose the evaluation period for the alarm. For **consecutive period(s) of**, choose the period during which the threshold must have been reached in order to trigger the alarm.
10. For **Name of alarm**, enter a name for the alarm.
11. Choose **Create Alarm**.

The alarm appears in the **CloudWatch alarms** section.

Evaluating performance metrics

A DB instance has a number of different categories of metrics, and how to determine acceptable values depends on the metric.

CPU

- CPU Utilization – Percentage of computer processing capacity used.

Memory

- Freeable Memory – How much RAM is available on the DB instance, in megabytes. The red line in the Monitoring tab metrics is marked at 75% for CPU, Memory and Storage Metrics. If instance memory consumption frequently crosses that line, then this indicates that you should check your workload or upgrade your instance.
- Swap Usage – How much swap space is used by the DB instance, in megabytes.

Disk space

- Free Storage Space – How much disk space is not currently being used by the DB instance, in megabytes.

Input/output operations

- Read IOPS, Write IOPS – The average number of disk read or write operations per second.
- Read Latency, Write Latency – The average time for a read or write operation in milliseconds.
- Read Throughput, Write Throughput – The average number of megabytes read from or written to disk per second.
- Queue Depth – The number of I/O operations that are waiting to be written to or read from disk.

Network traffic

- Network Receive Throughput, Network Transmit Throughput – The rate of network traffic to and from the DB instance in bytes per second.

Database connections

- DB Connections – The number of client sessions that are connected to the DB instance.

For more detailed individual descriptions of the performance metrics available, see [Monitoring Amazon RDS metrics with Amazon CloudWatch \(p. 528\)](#).

Generally speaking, acceptable values for performance metrics depend on what your baseline looks like and what your application is doing. Investigate consistent or trending variances from your baseline. Advice about specific types of metrics follows:

- **High CPU or RAM consumption** – High values for CPU or RAM consumption might be appropriate. For example, they might be so if they are in keeping with your goals for your application (like throughput or concurrency) and are expected.

- **Disk space consumption** – Investigate disk space consumption if space used is consistently at or above 85 percent of the total disk space. See if it is possible to delete data from the instance or archive data to a different system to free up space.
- **Network traffic** – For network traffic, talk with your system administrator to understand what expected throughput is for your domain network and internet connection. Investigate network traffic if throughput is consistently lower than expected.
- **Database connections** – Consider constraining database connections if you see high numbers of user connections in conjunction with decreases in instance performance and response time. The best number of user connections for your DB instance will vary based on your instance class and the complexity of the operations being performed. To determine the number of database connections, associate your DB instance with a parameter group. In this group, set the *User Connections* parameter to other than 0 (unlimited). You can either use an existing parameter group or create a new one. For more information, see [Working with parameter groups \(p. 289\)](#).
- **IOPS metrics** – The expected values for IOPS metrics depend on disk specification and server configuration, so use your baseline to know what is typical. Investigate if values are consistently different than your baseline. For best IOPS performance, make sure your typical working set will fit into memory to minimize read and write operations.

For issues with performance metrics, a first step to improve performance is to tune the most used and most expensive queries. Tune them to see if doing so lowers the pressure on system resources. For more information, see [Tuning queries \(p. 221\)](#).

If your queries are tuned and an issue persists, consider upgrading your Amazon RDS [DB instance classes \(p. 10\)](#). You might upgrade it to one with more of the resource (CPU, RAM, disk space, network bandwidth, I/O capacity) that is related to the issue.

Tuning queries

One of the best ways to improve DB instance performance is to tune your most commonly used and most resource-intensive queries. Here, you tune them to make them less expensive to run. For information on improving queries, use the following resources:

- MySQL – See [Optimizing SELECT statements](#) in the MySQL documentation. For additional query tuning resources, see [MySQL performance tuning and optimization resources](#).
- Oracle – See [Database SQL Tuning Guide](#) in the Oracle Database documentation.
- SQL Server – See [Analyzing a query](#) in the Microsoft documentation. You can also use the execution-, index-, and I/O-related data management views (DMVs) described in [System Dynamic Management Views](#) in the Microsoft documentation to troubleshoot SQL Server query issues.

A common aspect of query tuning is creating effective indexes. For potential index improvements for your DB instance, see [Database Engine Tuning Advisor](#) in the Microsoft documentation. For information on using Tuning Advisor on RDS for SQL Server, see [Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor \(p. 1294\)](#).

- PostgreSQL – See [Using EXPLAIN](#) in the PostgreSQL documentation to learn how to analyze a query plan. You can use this information to modify a query or underlying tables in order to improve query performance.

For information about how to specify joins in your query for the best performance, see [Controlling the planner with explicit JOIN clauses](#).

- MariaDB – See [Query optimizations](#) in the MariaDB documentation.

Best practices for working with MySQL

Both table sizes and number of tables in a MySQL database can affect performance.

Table size

Typically, operating system constraints on file sizes determine the effective maximum table size for MySQL databases. So, the limits usually aren't determined by internal MySQL constraints.

On a MySQL DB instance, avoid tables in your database growing too large. Although the general storage limit is 64 TiB, provisioned storage limits restrict the maximum size of a MySQL table file to 16 TiB. Partition your large tables so that file sizes are well under the 16 TiB limit. This approach can also improve performance and recovery time. For more information, see [MySQL file size limits in Amazon RDS \(p. 1437\)](#).

Very large tables (greater than 100 GB in size) can negatively affect performance for both reads and writes (including DML statements and especially DDL statements). Indexes on large tables can significantly improve select performance, but they can also degrade the performance of DML statements. DDL statements, such as ALTER TABLE, can be significantly slower for the large tables because those operations might completely rebuild a table in some cases. These DDL statements might lock the tables for the duration of the operation.

The amount of memory required by MySQL for reads and writes depends on the tables involved in the operations. It is a best practice to have at least enough RAM to hold the indexes of *actively used* tables. To find the ten largest tables and indexes in a database, use the following query:

```
select table_schema, TABLE_NAME, dat, idx from
(SELECT table_schema, TABLE_NAME,
      ( data_length ) / 1024 / 1024 as dat,
      ( index_length ) / 1024 / 1024 as idx
FROM information_schema.TABLES
order by 3 desc ) a
order by 3 desc
limit 10;
```

Number of tables

Your underlying file system might have a limit on the number of files that represent tables. However, MySQL has no limit on the number of tables. Despite this, the total number of tables in the MySQL InnoDB storage engine can contribute to the performance degradation, regardless of the size of those tables. To limit the operating system impact, you can split the tables across multiple databases in the same MySQL DB instance. Doing so might limit the number of files in a directory but won't solve the overall problem.

When there is performance degradation because of a large number of tables (more than 10 thousand), it is caused by MySQL working with storage files, including opening and closing them. To address this issue, you can increase the size of the table_open_cache and table_definition_cache parameters. However, increasing the values of those parameters might significantly increase the amount of memory MySQL uses, and might even use all of the available memory. For more information, see [How MySQL Opens and Closes Tables](#) in the MySQL documentation.

In addition, too many tables can significantly affect MySQL startup time. Both a clean shutdown and restart and a crash recovery can be affected, especially in versions prior to MySQL 8.0.

We recommend having fewer than 10,000 tables total across all of the databases in a DB instance. For a use case with a large number of tables in a MySQL database, see [One Million Tables in MySQL 8.0](#).

Storage engine

The point-in-time restore and snapshot restore features of Amazon RDS for MySQL require a crash-recoverable storage engine. These features are supported for the InnoDB storage engine only. Although MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for crash recovery and data durability. For example, the MyISAM storage engine doesn't support reliable crash recovery and might prevent a point-in-time restore or snapshot restore from working as intended. This might result in lost or corrupt data when MySQL is restarted after a crash.

InnoDB is the recommended and supported storage engine for MySQL DB instances on Amazon RDS. InnoDB instances can also be migrated to Aurora, while MyISAM instances can't be migrated. However, MyISAM performs better than InnoDB if you require intense, full-text search capability. If you still choose to use MyISAM with Amazon RDS, following the steps outlined in [Automated backups with unsupported MySQL storage engines \(p. 435\)](#) can be helpful in certain scenarios for snapshot restore functionality.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the process outlined in the [MySQL documentation](#). MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

In addition, Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

Best practices for working with MariaDB

Both table sizes and number of tables in a MariaDB database can affect performance.

Table size

Typically, operating system constraints on file sizes determine the effective maximum table size for MariaDB databases. So, the limits usually aren't determined by internal MariaDB constraints.

On a MariaDB DB instance, avoid tables in your database growing too large. Although the general storage limit is 64 TiB, provisioned storage limits restrict the maximum size of a MariaDB table file to 16 TiB. Partition your large tables so that file sizes are well under the 16 TiB limit. This approach can also improve performance and recovery time.

Very large tables (greater than 100 GB in size) can negatively affect performance for both reads and writes (including DML statements and especially DDL statements). Indexes on large tables can significantly improve select performance, but they can also degrade the performance of DML statements. DDL statements, such as ALTER TABLE, can be significantly slower for the large tables because those operations might completely rebuild a table in some cases. These DDL statements might lock the tables for the duration of the operation.

The amount of memory required by MariaDB for reads and writes depends on the tables involved in the operations. It is a best practice to have at least enough RAM to hold the indexes of *actively* used tables. To find the ten largest tables and indexes in a database, use the following query:

```
select table_schema, TABLE_NAME, dat, idx from
(SELECT table_schema, TABLE_NAME,
      ( data_length ) / 1024 / 1024 as dat,
      ( index_length ) / 1024 / 1024 as idx
FROM information_schema.TABLES
order by 3 desc ) a
order by 3 desc
limit 10;
```

Number of tables

Your underlying file system might have a limit on the number of files that represent tables. However, MariaDB has no limit on the number of tables. Despite this, the total number of tables in the MariaDB InnoDB storage engine can contribute to the performance degradation, regardless of the size of those tables. To limit the operating system impact, you can split the tables across multiple databases in the same MariaDB DB instance. Doing so might limit the number of files in a directory but doesn't solve the overall problem.

When there is performance degradation because of a large number of tables (more than 10,000), it's caused by MariaDB working with storage files. This work includes MariaDB opening and closing storage files. To address this issue, you can increase the size of the `table_open_cache` and `table_definition_cache` parameters. However, increasing the values of those parameters might significantly increase the amount of memory MariaDB uses. It might even use all of the available memory. For more information, see [Optimizing table_open_cache](#) in the MariaDB documentation.

In addition, too many tables can significantly affect MariaDB startup time. Both a clean shutdown and restart and a crash recovery can be affected. We recommend having fewer than ten thousand tables total across all of the databases in a DB instance.

Storage engine

The point-in-time restore and snapshot restore features of Amazon RDS for MariaDB require a crash-recoverable storage engine. Although MariaDB supports multiple storage engines with varying capabilities, not all of them are optimized for crash recovery and data durability. For example, although Aria is a crash-safe replacement for MyISAM, it might still prevent a point-in-time restore or snapshot restore from working as intended. This might result in lost or corrupt data when MariaDB is restarted after a crash. InnoDB is the recommended and supported storage engine for MariaDB DB instances on Amazon RDS. If you still choose to use Aria with Amazon RDS, following the steps outlined in [Automated backups with unsupported MariaDB storage engines \(p. 436\)](#) can be helpful in certain scenarios for snapshot restore functionality.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the process outlined in the [MariaDB documentation](#). MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

Best practices for working with Oracle

For information about best practices for working with Amazon RDS for Oracle, see [Best practices for running Oracle database on Amazon Web Services](#).

A 2020 AWS virtual workshop included a presentation on running production Oracle databases on Amazon RDS. A video of the presentation is available [here](#).

Best practices for working with PostgreSQL

Of two important areas where you can improve performance with RDS for PostgreSQL, one is when loading data into a DB instance. Another is when using the PostgreSQL autovacuum feature. The following sections cover some of the practices we recommend for these areas.

For information on how Amazon RDS implements other common PostgreSQL DBA tasks, see [Common DBA tasks for Amazon RDS for PostgreSQL \(p. 1915\)](#).

Loading data into a PostgreSQL DB instance

When loading data into an Amazon RDS for PostgreSQL DB instance, modify your DB instance settings and your DB parameter group values. Set these to allow for the most efficient importing of data into your DB instance.

Modify your DB instance settings to the following:

- Disable DB instance backups (set `backup_retention` to 0)
- Disable Multi-AZ

Modify your DB parameter group to include the following settings. Also, test the parameter settings to find the most efficient settings for your DB instance.

- Increase the value of the `maintenance_work_mem` parameter. For more information about PostgreSQL resource consumption parameters, see the [PostgreSQL documentation](#).
- Increase the value of the `max_wal_size` and `checkpoint_timeout` parameters to reduce the number of writes to the write-ahead log (WAL) log.
- Disable the `synchronous_commit` parameter.
- Disable the PostgreSQL autovacuum parameter.
- Make sure that none of the tables you're importing are unlogged. Data stored in unlogged tables can be lost during a failover. For more information, see [CREATE TABLE UNLOGGED](#).

Use the `pg_dump -Fc` (compressed) or `pg_restore -j` (parallel) commands with these settings.

After the load operation completes, return your DB instance and DB parameters to their normal settings.

Working with the PostgreSQL autovacuum feature

The autovacuum feature for PostgreSQL databases is a feature that we strongly recommend you use to maintain the health of your PostgreSQL DB instance. Autovacuum automates the execution of the `VACUUM` and `ANALYZE` command. Using autovacuum is required by PostgreSQL, not imposed by Amazon RDS, and its use is critical to good performance. The feature is enabled by default for all new Amazon RDS for PostgreSQL DB instances, and the related configuration parameters are appropriately set by default.

Your database administrator needs to know and understand this maintenance operation. For the PostgreSQL documentation on autovacuum, see [The Autovacuum Daemon](#).

Autovacuum is not a "resource free" operation, but it works in the background and yields to user operations as much as possible. When enabled, autovacuum checks for tables that have had a large number of updated or deleted tuples. It also protects against loss of very old data due to transaction ID wraparound. For more information, see [Preventing transaction ID wraparound failures](#).

Autovacuum should not be thought of as a high-overhead operation that can be reduced to gain better performance. On the contrary, tables that have a high velocity of updates and deletes will quickly deteriorate over time if autovacuum is not run.

Important

Not running autovacuum can result in an eventual required outage to perform a much more intrusive vacuum operation. In some cases, an RDS for PostgreSQL DB instance might become unavailable because of an over-conservative use of autovacuum. In these cases, the PostgreSQL database shuts down to protect itself. At that point, Amazon RDS must perform a single-user-mode full vacuum directly on the DB instance. This full vacuum can result in a multi-hour

outage. Thus, we strongly recommend that you do not turn off autovacuum, which is turned on by default.

The autovacuum parameters determine when and how hard autovacuum works. The `autovacuum_vacuum_threshold` and `autovacuum_vacuum_scale_factor` parameters determine when autovacuum is run. The `autovacuum_max_workers`, `autovacuum_nap_time`, `autovacuum_cost_limit`, and `autovacuum_cost_delay` parameters determine how hard autovacuum works. For more information about autovacuum, when it runs, and what parameters are required, see [Routine Vacuuming](#) in the PostgreSQL documentation.

The following query shows the number of "dead" tuples in a table named `table1`:

```
PROMPT> select relname, n_dead_tup, last_vacuum, last_autovacuum from pg_catalog.pg_stat_all_tables where n_dead_tup > 0 and relname = 'table1';
```

The results of the query will resemble the following:

relname	n_dead_tup	last_vacuum	last_autovacuum
tasks	81430522		

(1 row)

Amazon RDS for PostgreSQL best practices video

The 2020 AWS re:Invent conference included a presentation on new features and best practices for working with PostgreSQL on Amazon RDS. A video of the presentation is available [here](#).

Best practices for working with SQL Server

Best practices for a Multi-AZ deployment with a SQL Server DB instance include the following:

- Use Amazon RDS DB events to monitor failovers. For example, you can be notified by text message or email when a DB instance fails over. For more information about Amazon RDS events, see [Working with Amazon RDS event notification \(p. 650\)](#).
- If your application caches DNS values, set time to live (TTL) to less than 30 seconds. Setting TTL as so is a good practice in case there is a failover. In a failover, the IP address might change and the cached value might no longer be in service.
- We recommend that you *do not* enable the following modes because they turn off transaction logging, which is required for Multi-AZ:
 - Simple recover mode
 - Offline mode
 - Read-only mode
- Test to determine how long it takes for your DB instance to failover. Failover time can vary due to the type of database, the instance class, and the storage type you use. You should also test your application's ability to continue working if a failover occurs.
- To shorten failover time, do the following:
 - Ensure that you have sufficient Provisioned IOPS allocated for your workload. Inadequate I/O can lengthen failover times. Database recovery requires I/O.
 - Use smaller transactions. Database recovery relies on transactions, so if you can break up large transactions into multiple smaller transactions, your failover time should be shorter.

- Take into consideration that during a failover, there will be elevated latencies. As part of the failover process, Amazon RDS automatically replicates your data to a new standby instance. This replication means that new data is being committed to two different DB instances. So there might be some latency until the standby DB instance has caught up to the new primary DB instance.
- Deploy your applications in all Availability Zones. If an Availability Zone does go down, your applications in the other Availability Zones will still be available.

When working with a Multi-AZ deployment of SQL Server, remember that Amazon RDS creates replicas for all SQL Server databases on your instance. If you don't want specific databases to have secondary replicas, set up a separate DB instance that doesn't use Multi-AZ for those databases.

Amazon RDS for SQL Server best practices video

The 2019 AWS re:Invent conference included a presentation on new features and best practices for working with SQL Server on Amazon RDS. A video of the presentation is available [here](#).

Working with DB parameter groups

We recommend that you try out DB parameter group changes on a test DB instance before applying parameter group changes to your production DB instances. Improperly setting DB engine parameters in a DB parameter group can have unintended adverse effects, including degraded performance and system instability. Always exercise caution when modifying DB engine parameters and back up your DB instance before modifying a DB parameter group.

For information about backing up your DB instance, see [Backing up and restoring an Amazon RDS DB instance \(p. 426\)](#).

Best practices for automating DB instance creation

It's an Amazon RDS best practice to create a DB instance with the preferred minor version of the database engine. You can use the AWS CLI, Amazon RDS API, or AWS CloudFormation to automate DB instance creation. When you use these methods, you can specify only the major version and Amazon RDS automatically creates the instance with the preferred minor version. For example, if PostgreSQL 12.5 is the preferred minor version, and if you specify version 12 with `create-db-instance`, the DB instance will be version 12.5.

To determine the preferred minor version, you can run the `describe-db-engine-versions` command with the `--default-only` option as shown in the following example.

```
aws rds describe-db-engine-versions --default-only --engine postgres
{
    "DBEngineVersions": [
        {
            "Engine": "postgres",
            "EngineVersion": "12.5",
            "DBParameterGroupFamily": "postgres12",
            "DBEngineDescription": "PostgreSQL",
            "DBEngineVersionDescription": "PostgreSQL 12.5-R1",
            "...some output truncated..."
        }
    ]
}
```

For information on creating DB instances programmatically, see the following resources:

- Using the AWS CLI – [create-db-instance](#)
- Using the Amazon RDS API – [CreateDBInstance](#)
- Using AWS CloudFormation – [AWS::RDS::DBInstance](#)

Amazon RDS new features and best practices presentation video

The 2019 AWS re:Invent conference included a presentation on new Amazon RDS features and best practices for monitoring, analyzing, and tuning database performance using RDS. A video of the presentation is available [here](#).

Configuring an Amazon RDS DB instance

This section shows how to set up your Amazon RDS DB instance. Before creating a DB instance, decide on the DB instance class that will run the DB instance. Also, decide where the DB instance will run by choosing an AWS Region. Next, create the DB instance.

You can configure a DB instance with an option group and a DB parameter group.

- An *option group* specifies features, called options, that are available for a particular Amazon RDS DB instance.
- A *DB parameter group* acts as a container for engine configuration values that are applied to one or more DB instances.

The options and parameters that are available depend on the DB engine and DB engine version. You can specify an option group and a DB parameter group when you create a DB instance. You can also modify a DB instance to specify them.

Topics

- [Creating an Amazon RDS DB instance \(p. 230\)](#)
- [Creating a Multi-AZ DB cluster \(p. 252\)](#)
- [Creating Amazon RDS resources with AWS CloudFormation \(p. 266\)](#)
- [Connecting to an Amazon RDS DB instance \(p. 267\)](#)
- [Working with option groups \(p. 273\)](#)
- [Working with parameter groups \(p. 289\)](#)

Creating an Amazon RDS DB instance

The basic building block of Amazon RDS is the DB instance, where you create your databases. You choose the engine-specific characteristics of the DB instance when you create it. You also choose the storage capacity, CPU, memory, and so on, of the AWS instance on which the database server runs.

Topics

- [DB instance prerequisites \(p. 230\)](#)
- [Creating a DB instance \(p. 233\)](#)
- [Settings for DB instances \(p. 237\)](#)

DB instance prerequisites

Important

Before you can create an Amazon RDS DB instance, you must complete the tasks in [Setting up for Amazon RDS \(p. 148\)](#).

The following are prerequisites to complete before creating a DB instance.

Topics

- [Configure the network for the DB instance \(p. 230\)](#)
- [Additional prerequisites \(p. 233\)](#)

Configure the network for the DB instance

You can create an Amazon RDS DB instance only in a virtual private cloud (VPC) based on the Amazon VPC service. Also, it must be in an AWS Region that has at least two Availability Zones. The DB subnet group that you choose for the DB instance must cover at least two Availability Zones. This configuration ensures that you can configure a Multi-AZ deployment when you create the DB instance or easily move to one in the future.

To set up connectivity between your new DB instance and an Amazon EC2 instance in the same VPC, do so when you create the DB instance. To connect to your DB instance from resources other than EC2 instances in the same VPC, configure the network connections manually.

Topics

- [Configure automatic network connectivity with an EC2 instance \(p. 230\)](#)
- [Configure the network manually \(p. 232\)](#)

Configure automatic network connectivity with an EC2 instance

When you create an RDS DB instance, you can use the AWS Management Console to set up connectivity between an EC2 instance and the new DB instance. When you do so, RDS configures your VPC and network settings automatically. The DB instance is created in the same VPC as the EC2 instance so that the EC2 instance can access the DB instance.

The following are requirements for connecting an EC2 instance with the DB instance:

- The EC2 instance must exist in the AWS Region before you create the DB instance.

If no EC2 instances exist in the AWS Region, the console provides a link to create one.

- The user who is creating the DB instance must have permissions to perform the following operations:
 - ec2:AssociateRouteTable
 - ec2:AuthorizeSecurityGroupEgress
 - ec2>CreateRouteTable
 - ec2>CreateSubnet
 - ec2>CreateSecurityGroup
 - ec2:DescribeInstances
 - ec2:DescribeNetworkInterfaces
 - ec2:DescribeRouteTables
 - ec2:DescribeSecurityGroups
 - ec2:DescribeSubnets
 - ec2:ModifyNetworkInterfaceAttribute
 - ec2:RevokeSecurityGroupEgress

Using this option creates a private DB instance. The DB instance uses a DB subnet group with only private subnets to restrict access to resources within the VPC.

To connect an EC2 instance to the DB instance, choose **Connect to an EC2 compute resource** in the **Connectivity** section on the [Create database](#) page.

Connectivity Info C

Compute resource
Choose whether to set up a connection to a compute resource for this database. Setting up a connection will automatically change connectivity settings so that the compute resource can connect to this database.

Don't connect to an EC2 compute resource
Don't set up a connection to a compute resource for this database. You can manually set up a connection to a compute resource later.

Connect to an EC2 compute resource
Set up a connection to an EC2 compute resource for this database.

EC2 Instance Info
Choose the EC2 instance to add as the compute resource for this database. A VPC security group is added to this EC2 instance. A VPC security group is also added to the database with an inbound rule that allows the EC2 instance to access the database.

[Choose EC2 instances](#) ▼

When you choose **Connect to an EC2 compute resource**, RDS sets the following options automatically. You can't change these settings unless you choose not to set up connectivity with an EC2 instance by choosing **Don't connect to an EC2 compute resource**.

Console option	Automatic setting
Network type	RDS sets network type to IPv4 . Currently, dual-stack mode isn't supported when you set up a connection between an EC2 instance and the DB instance.
Virtual Private Cloud (VPC)	RDS sets the VPC to the one associated with the EC2 instance.
DB subnet group	A DB subnet group with a private subnet in each Availability Zone in the AWS Region is required. If a DB subnet group that meets this requirement exists, RDS uses the existing DB subnet group.

Console option	Automatic setting
	<p>In some cases, a DB subnet group that meets this requirement doesn't exist. If not, RDS uses an available private subnet in each Availability Zone to create a DB subnet group using the private subnets. If a private subnet isn't available in an Availability Zone, RDS creates a private subnet in the Availability Zone. RDS then creates the DB subnet group.</p> <p>When a private subnet is available, RDS uses the route table associated with it. RDS then adds any subnets it creates to this route table. When no private subnet is available, RDS creates a route table with no internet gateway access. RDS then adds the subnets it creates to the route table.</p>
Public access	<p>RDS chooses No so that the DB instance isn't publicly accessible.</p> <p>For security, it is a best practice to keep the database private and make sure it isn't accessible from the internet.</p>
VPC security group (firewall)	<p>RDS creates a new security group that is associated with the DB instance. The security group is named <code>rds-ec2-n</code>, where <code>n</code> is a number. This security group includes an inbound rule with the EC2 VPC security group (firewall) as the source. This security group that is associated with the DB instance allows the EC2 instance to access the DB instance.</p> <p>RDS also creates a new security group that is associated with the EC2 instance. The security group is named <code>ec2-rds-n</code>, where <code>n</code> is a number. This security group includes an outbound rule with the VPC security group of the DB instance as the source. This security group allows the EC2 instance to send traffic to the DB instance.</p> <p>You can add another new security group by choosing Create new and typing the name of the new security group.</p> <p>You can add existing security groups by choosing Choose existing and selecting security groups to add.</p>
Availability Zone	<p>When you choose Single DB instance in Availability & durability (Single-AZ deployment), RDS chooses the Availability Zone of the EC2 instance.</p> <p>When you choose Multi-AZ DB instance in Availability & durability (Multi-AZ DB instance deployment), RDS chooses the Availability Zone of the EC2 instance for one DB instance in the deployment. RDS randomly chooses a different Availability Zone for the other DB instance. Either the primary DB instance or the standby replica is created in the same Availability Zone as the EC2 instance. When you choose Multi-AZ DB instance, there is the possibility of cross Availability Zone costs if the DB instance and EC2 instance are in different Availability Zones.</p>

For more information about these settings, see [Settings for DB instances \(p. 237\)](#).

If you change these settings after the DB instance is created, the changes might affect the connection between the EC2 instance and the DB instance.

Configure the network manually

To connect to your DB instance from resources other than EC2 instances in the same VPC, configure the network connections manually. If you use the AWS Management Console to create your DB instance, you can have Amazon RDS automatically create a VPC for you. Or you can use an existing VPC or create a

new VPC for your DB instance. With any approach, your VPC requires at least one subnet in each of at least two Availability Zones for use with an RDS DB instance.

By default, Amazon RDS creates the DB instance in an Availability Zone automatically for you. To choose a specific Availability Zone, you need to change the **Availability & durability** setting to **Single DB instance**. Doing so exposes an **Availability Zone** setting that lets you choose from among the Availability Zones in your VPC. However, if you choose a Multi-AZ deployment, RDS chooses the Availability Zone of the primary or writer DB instance automatically, and the **Availability Zone** setting doesn't appear.

In some cases, you might not have a default VPC or haven't created a VPC. In these cases, you can have Amazon RDS automatically create a VPC for you when you create a DB instance using the console. Otherwise, do the following:

- Create a VPC with at least one subnet in each of at least two of the Availability Zones in the AWS Region where you want to deploy your DB instance. For more information, see [Working with a DB instance in a VPC \(p. 2104\)](#) and [Tutorial: Create a VPC for use with a DB instance \(IPv4 only\) \(p. 2120\)](#).
- Specify a VPC security group that authorizes connections to your DB instance. For more information, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#) and [Controlling access with security groups \(p. 2085\)](#).
- Specify an RDS DB subnet group that defines at least two subnets in the VPC that can be used by the DB instance. For more information, see [Working with DB subnet groups \(p. 2104\)](#).

Additional prerequisites

Before you create your DB instance, consider the following additional prerequisites:

- If you are connecting to AWS using AWS Identity and Access Management (IAM) credentials, your AWS account must have certain IAM policies. These grant the permissions required to perform Amazon RDS operations. For more information, see [Identity and access management for Amazon RDS \(p. 2016\)](#).

To use IAM to access the RDS console, sign in to the AWS Management Console with your IAM user credentials. Then go to the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

- To tailor the configuration parameters for your DB instance, specify a DB parameter group with the required parameter settings. For information about creating or modifying a DB parameter group, see [Working with parameter groups \(p. 289\)](#).
- Determine the TCP/IP port number to specify for your DB instance. The firewalls at some companies block connections to the default ports for RDS DB instances. If your company firewall blocks the default port, choose another port for your DB instance.

Creating a DB instance

You can create an Amazon RDS DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

Console

You can create a DB instance by using the AWS Management Console with **Easy create** enabled or not enabled. With **Easy create** enabled, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default setting for other configuration options. With **Easy create** not enabled, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

Note

In the following procedure, **Standard create** is enabled, and **Easy create** isn't enabled. This procedure uses Microsoft SQL Server as an example.

For examples that use **Easy create** to walk you through creating and connecting to sample DB instances for each engine, see [Getting started with Amazon RDS \(p. 153\)](#).

To create a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. In **Choose a database creation method**, select **Standard Create**.
6. In **Engine options**, choose the engine type: MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL. **Microsoft SQL Server** is shown here.

Create database

Choose a database creation method Info

Standard create
You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy create
Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

Engine options

Engine type Info

Amazon Aurora 

MySQL 

MariaDB 

PostgreSQL 

Oracle 

Microsoft SQL Server 

Edition

SQL Server Express Edition
Affordable database management system that supports database sizes up to 10 GB.

SQL Server Web Edition
In accordance with Microsoft's licensing policies, it can only be used to support public and Internet-accessible webpages, websites, web applications, and web services.

SQL Server Standard Edition
Core data management and business intelligence capabilities for mission-critical applications and mixed workloads.

SQL Server Enterprise Edition
For more information about the editions, see [Editions and features](#).

7. For **Edition**, if you're using Oracle or SQL Server choose the DB engine edition that you want to use.

MySQL has only one option for the edition, and MariaDB and PostgreSQL have none.

8. For **Version**, choose the engine version.
9. In **Templates**, choose the template that matches your use case. If you choose **Production**, the following are preselected in a later step:
 - **Multi-AZ failover option**
 - **Provisioned IOPS SSD (io1) storage option**
 - **Enable deletion protection** option

We recommend these features for any production environment.

Note

Template choices vary by edition.

10. To enter your master password, do the following:
 - a. In the **Settings** section, open **Credential Settings**.
 - b. If you want to specify a password, clear the **Auto generate a password** check box if it is selected.
 - c. (Optional) Change the **Master username** value.
 - d. Enter the same password in **Master password** and **Confirm password**.
11. (Optional) Set up a connection to a compute resource for this DB instance.

You can configure connectivity between an Amazon EC2 instance and the new DB instance during DB instance creation. For more information, see [Configure automatic network connectivity with an EC2 instance \(p. 230\)](#).

12. For the remaining sections, specify your DB instance settings. For information about each setting, see [Settings for DB instances \(p. 237\)](#).
13. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

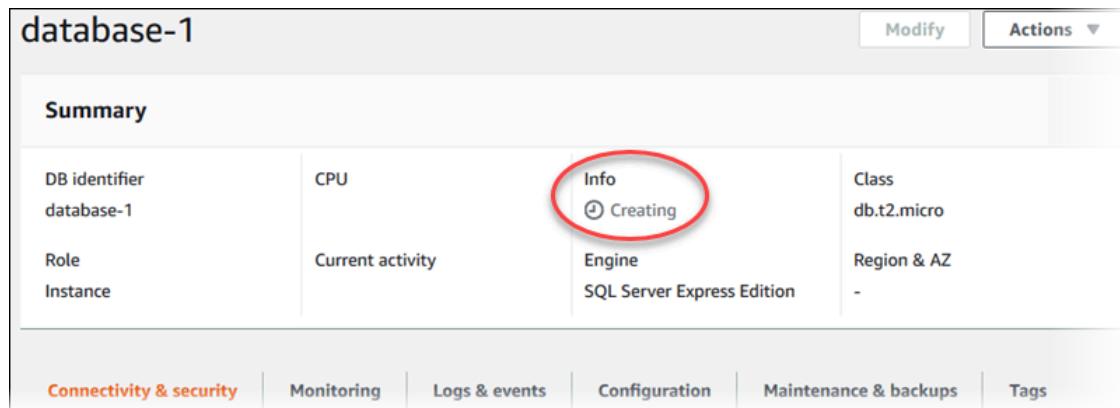

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

14. For **Databases**, choose the name of the new DB instance.

On the RDS console, the details for the new DB instance appear. The DB instance has a status of **Creating** until the DB instance is created and ready for use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and storage allocated, it can take several minutes for the new instance to be available.

AWS CLI

To create a DB instance by using the AWS CLI, call the [create-db-instance](#) command with the following parameters:

- `--db-instance-identifier`
- `--db-instance-class`
- `--vpc-security-group-ids`
- `--db-subnet-group`
- `--engine`
- `--master-username`
- `--master-user-password`
- `--allocated-storage`
- `--backup-retention-period`

For information about each setting, see [Settings for DB instances \(p. 237\)](#).

This example uses Microsoft SQL Server.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--engine sqlserver-se \
--db-instance-identifier mymssqlserver \
--allocated-storage 250 \
--db-instance-class db.t3.large \
--vpc-security-group-ids mysecuritygroup \
--db-subnet-group mydbsubnetgroup \
--master-username masterawsuser \
--master-user-password masteruserpassword \
--backup-retention-period 3
```

For Windows:

```
aws rds create-db-instance ^
--engine sqlserver-se ^
--db-instance-identifier mydbinstance ^
--allocated-storage 250 ^
```

```
--db-instance-class db.t3.large ^
--vpc-security-group-ids mysecuritygroup ^
--db-subnet-group mydbsubnetgroup ^
--master-username masterawsuser ^
--master-user-password masteruserpassword ^
--backup-retention-period 3
```

This command produces output similar to the following.

```
DBINSTANCE mydbinstance db.t3.large sqlserver-se 250 sa creating 3 **** n
10.50.2789
SECGROUP default active
PARAMGRP default.sqlserver-se-14 in-sync
```

RDS API

To create a DB instance by using the Amazon RDS API, call the [CreateDBInstance](#) operation.

For information about each setting, see [Settings for DB instances \(p. 237\)](#).

Settings for DB instances

In the following table, you can find details about settings that you choose when you create a DB instance. The table also shows the DB engines for which each setting is supported.

You can create a DB instance using the console, the [create-db-instance](#) CLI command, or the [CreateDBInstance](#) RDS API operation.

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Allocated storage	<p>The amount of storage to allocate for your DB instance (in gibibytes). In some cases, allocating a higher amount of storage for your DB instance than the size of your database can improve I/O performance.</p> <p>For more information, see Amazon RDS DB instance storage (p. 64).</p>	CLI option: --allocated-storage API parameter: AllocatedStorage	All
Architecture settings	<p>The architecture of the database: CDB (single-tenant) or non-CDB. Oracle Database 21c uses CDB architecture only. Oracle Database 19c can use either CDB or non-CDB architecture. Releases lower than Oracle Database 19c use non-CDB only.</p> <p>If you choose Use multitenant architecture, RDS for Oracle creates a container database (CDB). This CDB contains one pluggable database (PDB). If you don't choose this option, RDS for Oracle creates</p>	CLI option: --engine oracle-ee-cdb (multitenant) --engine oracle-se2-cdb (multitenant) --engine oracle-ee (traditional) --engine oracle-se2 (traditional) API parameter: Engine	Oracle

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
	<p>a non-CDB. A non-CDB uses the traditional Oracle architecture.</p> <p>For more information, see RDS for Oracle architecture (p. 1480).</p>		
Auto minor version upgrade	<p>Enable auto minor version upgrade to enable your DB instance to receive preferred minor DB engine version upgrades automatically when they become available. Amazon RDS performs automatic minor version upgrades in the maintenance window.</p> <p>For more information, see Automatically upgrading the minor engine version (p. 362).</p>	CLI option: --auto-minor-version-upgrade --no-auto-minor-version-upgrade API parameter: AutoMinorVersionUpgrade	All
Availability zone	<p>The Availability Zone for your DB instance. Use the default value of No Preference unless you want to specify an Availability Zone.</p> <p>For more information, see Regions, Availability Zones, and Local Zones (p. 72).</p>	CLI option: --availability-zone API parameter: AvailabilityZone	All
AWS KMS key	Only available if Encryption is set to Enable encryption . Choose the AWS KMS key to use for encrypting this DB instance. For more information, see Encrypting Amazon RDS resources (p. 2000) .	CLI option: --kms-key-id API parameter: KmsKeyId	All
Backup replication	<p>Choose Enable replication in another AWS Region to create backups in an additional Region for disaster recovery.</p> <p>Then choose the Destination Region for the additional backups.</p>	Not available when creating a DB instance. For information on enabling cross-Region backups using the AWS CLI or RDS API, see Enabling cross-Region automated backups (p. 439) .	Oracle PostgreSQL SQL Server
Backup retention period	<p>The number of days that you want automatic backups of your DB instance to be retained. For any nontrivial DB instance, set this value to 1 or greater.</p> <p>For more information, see Working with backups (p. 427).</p>	CLI option: --backup-retention-period API parameter: BackupRetentionPeriod	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Backup target	<p>Choose AWS Cloud to store automated backups and manual snapshots in the parent AWS Region. Choose Outposts (on-premises) to store them locally on your Outpost.</p> <p>This option setting applies only to RDS on Outposts. For more information, see Creating DB instances for Amazon RDS on AWS Outposts (p. 914).</p>	CLI option: <code>--backup-target</code> API parameter: <code>BackupTarget</code>	MySQL, PostgreSQL, SQL Server
Backup window	<p>The time period during which Amazon RDS automatically takes a backup of your DB instance. Unless you have a specific time that you want to have your database backed up, use the default of No Preference.</p> <p>For more information, see Working with backups (p. 427).</p>	CLI option: <code>--preferred-backup-window</code> API parameter: <code>PreferredBackupWindow</code>	All
Character set	<p>The character set for your DB instance. The default value of AL32UTF8 for the DB character set is for the Unicode 5.0 UTF-8 Universal character set. You can't change the DB character set after you create the DB instance.</p> <p>In a single-tenant configuration, a non-default DB character set affects only the PDB, not the CDB. For more information, see RDS for Oracle architecture (p. 1480).</p> <p>The DB character set is different from the national character set, which is called the NCHAR character set. Unlike the DB character set, the NCHAR character set specifies the encoding for NCHAR data types (NCHAR, NVARCHAR2, and NCLOB) columns without affecting database metadata.</p> <p>For more information, see RDS for Oracle character sets (p. 1482).</p>	CLI option: <code>--character-set-name</code> API parameter: <code>CharacterSetName</code>	Oracle

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Collation	A server-level collation for your DB instance. For more information, see Server-level collation for Microsoft SQL Server (p. 1296) .	CLI option: --character-set-name API parameter: CharacterSetName	SQL Server
Copy tags to snapshots	This option copies any DB instance tags to a DB snapshot when you create a snapshot. For more information, see Tagging Amazon RDS resources (p. 392) .	CLI option: --copy-tags-to-snapshot --no-copy-tags-to-snapshot RDS API parameter: CopyTagsToSnapshot	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Database authentication	<p>The database authentication option that you want to use.</p> <p>Choose Password authentication to authenticate database users with database passwords only.</p> <p>Choose Password and IAM DB authentication to authenticate database users with database passwords and user credentials through IAM users and roles. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2048). This option is only supported for MySQL and PostgreSQL.</p> <p>Choose Password and Kerberos authentication to authenticate database users with database passwords and Kerberos authentication through an AWS Managed Microsoft AD created with AWS Directory Service. Next, choose the directory or choose Create a new Directory.</p> <p>For more information, see one of the following:</p> <ul style="list-style-type: none"> • Using Kerberos authentication for MySQL (p. 1333) • Configuring Kerberos authentication for Amazon RDS for Oracle (p. 1501) • Using Kerberos authentication with Amazon RDS for PostgreSQL (p. 1823) 	<p>IAM:</p> <p>CLI option:</p> <pre>--enable-iam-database-authentication</pre> <p>RDS API parameter:</p> <pre>EnableIAMDatabaseAuthentication</pre> <p>Kerberos:</p> <p>CLI option:</p> <pre>--domain</pre> <pre>--domain-iam-role-name</pre> <p>RDS API parameter:</p> <pre>Domain</pre> <pre>DomainIAMRoleName</pre>	Varies by authentication type
Database management type	<p>Choose Amazon RDS if you don't need to customize your environment.</p> <p>Choose Amazon RDS Custom if you want to customize the database, OS, and infrastructure. For more information, see Working with Amazon RDS Custom (p. 755).</p>	For the CLI and API, you specify the database engine type.	Oracle SQL Server

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Database port	<p>The port that you want to access the DB instance through. The default port is shown.</p> <p>Note The firewalls at some companies block connections to the default MariaDB, MySQL, and PostgreSQL ports. If your company firewall blocks the default port, enter another port for your DB instance.</p>	<p>CLI option: --port</p> <p>RDS API parameter: Port</p>	All
DB engine version	The version of database engine that you want to use.	<p>CLI option: --engine-version</p> <p>RDS API parameter: EngineVersion</p>	All
DB instance class	<p>The configuration for your DB instance. For example, a db.t3.small DB instance class has 2 GiB memory, 2 vCPUs, 1 virtual core, a variable ECU, and a moderate I/O capacity.</p> <p>If possible, choose a DB instance class large enough that a typical query working set can be held in memory. When working sets are held in memory, the system can avoid writing to disk, which improves performance. For more information, see DB instance classes (p. 10).</p> <p>In RDS for Oracle, you can select Include additional memory configurations. These configurations are optimized for a high ratio of memory to vCPU. For example, db.r5.6xlarge.tpc2.mem4x is a db.r5.8x DB instance that has 2 threads per core (tpc2) and 4x the memory of a standard db.r5.6xlarge DB instance. For more information, see RDS for Oracle instance classes (p. 1477).</p>	<p>CLI option: --db-instance-class</p> <p>RDS API parameter: DBInstanceClass</p>	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
DB instance identifier	The name for your DB instance. Name your DB instances in the same way that you name your on-premises servers. Your DB instance identifier can contain up to 63 alphanumeric characters, and must be unique for your account in the AWS Region you chose.	CLI option: <code>--db-instance-identifier</code> RDS API parameter: <code>DBInstanceIdentifier</code>	All
DB parameter group	A parameter group for your DB instance. You can choose the default parameter group, or you can create a custom parameter group. For more information, see Working with parameter groups (p. 289) .	CLI option: <code>--db-parameter-group-name</code> RDS API parameter: <code>DBParameterGroupName</code>	All
DB subnet group	A DB subnet group to associate with this DB instance. For more information, see Working with DB subnet groups (p. 2104) .	CLI option: <code>--db-subnet-group-name</code> RDS API parameter: <code>DBSubnetGroupName</code>	All
Deletion protection	Enable deletion protection to prevent your DB instance from being deleted. If you create a production DB instance with the AWS Management Console, deletion protection is enabled by default. For more information, see Deleting a DB instance (p. 421) .	CLI option: <code>--deletion-protection</code> <code>--no-deletion-protection</code> RDS API parameter: <code>DeletionProtection</code>	All
Encryption	Enable Encryption to enable encryption at rest for this DB instance. For more information, see Encrypting Amazon RDS resources (p. 2000) .	CLI option: <code>--storage-encrypted</code> <code>--no-storage-encrypted</code> RDS API parameter: <code>StorageEncrypted</code>	All
Enhanced Monitoring	Enable enhanced monitoring to enable gathering metrics in real time for the operating system that your DB instance runs on. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 600) .	CLI options: <code>--monitoring-interval</code> <code>--monitoring-role-arn</code> RDS API parameters: <code>MonitoringInterval</code> <code>MonitoringRoleArn</code>	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Engine type	Choose the database engine to be used for this DB instance.	CLI option: --engine RDS API parameter: Engine	All
Initial database name	<p>The name for the database on your DB instance. If you don't provide a name, Amazon RDS doesn't create a database on the DB instance (except for Oracle and PostgreSQL). The name can't be a word reserved by the database engine, and has other constraints depending on the DB engine.</p> <p>MariaDB and MySQL:</p> <ul style="list-style-type: none"> It must contain 1–64 alphanumeric characters. <p>Oracle:</p> <ul style="list-style-type: none"> It must contain 1–8 alphanumeric characters. It can't be NULL. The default value is ORCL. It must begin with a letter. <p>PostgreSQL:</p> <ul style="list-style-type: none"> It must contain 1–63 alphanumeric characters. It must begin with a letter or an underscore. Subsequent characters can be letters, underscores, or digits (0–9). The initial database name is <code>postgres</code>. 	CLI option: --db-name RDS API parameter: DBName	All except SQL Server
License	<p>The license model:</p> <ul style="list-style-type: none"> Choose license-included for Microsoft SQL Server. Choose license-included or bring-your-own-license for Oracle. 	CLI option: --license-model RDS API parameter: LicenseModel	Oracle SQL Server

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Log exports	The types of database log files to publish to Amazon CloudWatch Logs. For more information, see Publishing database logs to Amazon CloudWatch Logs (p. 683) .	CLI option: --enable-cloudwatch-logs-exports RDS API parameter: EnableCloudwatchLogsExports	All
Maintenance window	The 30-minute window in which pending modifications to your DB instance are applied. If the time period doesn't matter, choose No Preference . For more information, see The Amazon RDS maintenance window (p. 354) .	CLI option: --preferred-maintenance-window RDS API parameter: PreferredMaintenanceWindow	All
Master password	The password for your master user account. The password has the following number of printable ASCII characters (excluding /, ", a space, and @) depending on the DB engine: <ul style="list-style-type: none">• Oracle: 8–30• MariaDB and MySQL: 8–41• SQL Server and PostgreSQL: 8–128	CLI option: --master-user-password RDS API parameter: MasterUserPassword	All
Master username	The name that you use as the master user name to log on to your DB instance with all database privileges. <ul style="list-style-type: none">• It can contain 1–16 alphanumeric characters and underscores.• Its first character must be a letter.• It can't be a word reserved by the database engine. You can't change the master user name after the DB instance is created. For more information on privileges granted to the master user, see Master user account privileges (p. 2087) .	CLI option: --master-username RDS API parameter: MasterUsername	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Microsoft SQL Server Windows Authentication	Enable Microsoft SQL Server Windows authentication , then Browse Directory to choose the directory where you want to allow authorized domain users to authenticate with this SQL Server instance using Windows Authentication.	CLI options: --domain --domain-iam-role-name RDS API parameters: Domain DomainIAMRoleName	SQL Server
Multi-AZ deployment	Create a standby instance to create a passive secondary replica of your DB instance in another Availability Zone for failover support. We recommend Multi-AZ for production workloads to maintain high availability. For development and testing, you can choose Do not create a standby instance . For more information, see Multi-AZ deployments for high availability (p. 121) .	CLI option: --multi-az --no-multi-az RDS API parameter: MultiAZ	All
National character set (NCHAR)	The national character set for your DB instance, commonly called the NCHAR character set. You can set the national character set to either AL16UTF16 (default) or UTF-8. You can't change the national character set after you create the DB instance. The national character set is different from the DB character set. Unlike the DB character set, the national character set specifies the encoding only for NCHAR data types (NCHAR, NVARCHAR2, and NCLOB) columns without affecting database metadata. For more information, see RDS for Oracle character sets (p. 1482) .	CLI option: --nchar-character-set-name API parameter: NcharCharacterSetName	Oracle

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Network type	<p>The IP addressing protocols supported by the DB instance.</p> <p>IPv4 (the default) to specify that resources can communicate with the DB instance only over the Internet Protocol version 4 (IPv4) addressing protocol.</p> <p>Dual-stack mode to specify that resources can communicate with the DB instance over IPv4, Internet Protocol version 6 (IPv6), or both. Use dual-stack mode if you have any resources that must communicate with your DB instance over the IPv6 addressing protocol. Also, make sure that you associate an IPv6 CIDR block with all subnets in the DB subnet group that you specify.</p> <p>For more information, see Amazon RDS IP addressing (p. 2105).</p>	<p>CLI option: <code>--network-type</code></p> <p>RDS API parameter: <code>NetworkType</code></p>	All
Option group	<p>An option group for your DB instance. You can choose the default option group or you can create a custom option group.</p> <p>For more information, see Working with option groups (p. 273).</p>	<p>CLI option: <code>--option-group-name</code></p> <p>RDS API parameter: <code>OptionGroupName</code></p>	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Performance Insights	<p>Enable Performance Insights to monitor your DB instance load so that you can analyze and troubleshoot your database performance.</p> <p>Choose a retention period to determine how much Performance Insights data history to keep. The retention setting in the free tier is Default (7 days). To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights (p. 548).</p> <p>Choose a KMS key to use to protect the key used to encrypt this database volume. Choose from the KMS keys in your account, or enter the key from a different account.</p> <p>For more information, see Monitoring DB load with Performance Insights on Amazon RDS (p. 543).</p>	<p>CLI options:</p> <pre>--enable-performance-insights --no-enable-performance-insights --performance-insights-retention-period --performance-insights-kms-key-id</pre> <p>RDS API parameters:</p> <pre>EnablePerformanceInsights PerformanceInsightsRetentionPeriod PerformanceInsightsKMSKeyId</pre>	All
Provisioned IOPS	<p>The Provisioned IOPS (I/O operations per second) value for the DB instance. This setting is available only if you choose one of the following for Storage type:</p> <ul style="list-style-type: none"> • General purpose SSD (gp3) • Provisioned IOPS SSD (io1) <p>For more information, see Amazon RDS DB instance storage (p. 64).</p>	<p>CLI option:</p> <pre>--iops</pre> <p>RDS API parameter:</p> <pre>Iops</pre>	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Public access	<p>Yes to give the DB instance a public IP address, meaning that it's accessible outside the VPC. To be publicly accessible, the DB instance also has to be in a public subnet in the VPC.</p> <p>No to make the DB instance accessible only from inside the VPC.</p> <p>For more information, see Hiding a DB instance in a VPC from the internet (p. 2109).</p> <p>To connect to a DB instance from outside of its VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group. In addition, other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 2141).</p> <p>If your DB instance isn't publicly accessible, use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 2015).</p>	<p>CLI option:</p> <pre>--publicly-accessible --no-publicly-accessible</pre> <p>RDS API parameter:</p> <pre>PubliclyAccessible</pre>	All
RDS Proxy	<p>Choose Create an RDS Proxy to create a proxy for your DB instance. Amazon RDS automatically creates an IAM role and a Secrets Manager secret for the proxy.</p> <p>For more information, see Using Amazon RDS Proxy (p. 921).</p>	Not available when creating a DB instance.	MariaDB MySQL PostgreSQL

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Storage autoscaling	<p>Enable storage autoscaling to enable Amazon RDS to automatically increase storage when needed to avoid having your DB instance run out of storage space.</p> <p>Use Maximum storage threshold to set the upper limit for Amazon RDS to automatically increase storage for your DB instance. The default is 1,000 GiB.</p> <p>For more information, see Managing capacity automatically with Amazon RDS storage autoscaling (p. 412).</p>	CLI option: <code>--max-allocated-storage</code> RDS API parameter: <code>MaxAllocatedStorage</code>	All
Storage throughput	<p>The storage throughput value for the DB instance. This setting is available only if you choose General purpose SSD (gp3) for Storage type.</p> <p>For more information, see Amazon RDS DB instance storage (p. 64).</p>	CLI option: <code>--storage-throughput</code> RDS API parameter: <code>StorageThroughput</code>	All
Storage type	<p>The storage type for your DB instance.</p> <p>If you choose General Purpose SSD (gp3), you can provision additional provisioned IOPS and storage throughput under Advanced settings.</p> <p>If you choose Provisioned IOPS SSD (io1), enter the Provisioned IOPS value.</p> <p>For more information, see Amazon RDS storage types (p. 64).</p>	CLI option: <code>--storage-type</code> RDS API parameter: <code>StorageType</code>	All
Subnet group	<p>A DB subnet group to associate with this DB instance.</p> <p>For more information, see Working with DB subnet groups (p. 2104).</p>	CLI option: <code>--db-subnet-group-name</code> RDS API parameter: <code>DBSubnetGroupName</code>	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Time zone	<p>The time zone for your DB instance. If you don't choose a time zone, your DB instance uses the default time zone. You can't change the time zone after the DB instance is created.</p> <p>For more information, see Local time zone for Microsoft SQL Server DB instances (p. 1074).</p>	<p>CLI option: <code>--timezone</code></p> <p>RDS API parameter: <code>Timezone</code></p>	SQL Server
Virtual Private Cloud (VPC)	<p>A VPC based on the Amazon VPC service to associate with this DB instance.</p> <p>For more information, see Amazon VPC VPCs and Amazon RDS (p. 2103).</p>	For the CLI and API, you specify the VPC security group IDs.	All
VPC security group (firewall)	<p>The security group to associate with the DB instance.</p> <p>For more information, see Overview of VPC security groups (p. 2085).</p>	<p>CLI option: <code>--vpc-security-group-ids</code></p> <p>RDS API parameter: <code>VpcSecurityGroupIds</code></p>	All

Creating a Multi-AZ DB cluster

A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower latency when compared to Multi-AZ deployments. For more information about Multi-AZ DB clusters, see [Multi-AZ DB cluster deployments \(p. 127\)](#).

Note

Multi-AZ DB clusters are supported only for the MySQL and PostgreSQL DB engines.

DB cluster prerequisites

Important

Before you can create a Multi-AZ DB cluster, you must complete the tasks in [Setting up for Amazon RDS \(p. 148\)](#).

The following are prerequisites to complete before creating a Multi-AZ DB cluster.

Topics

- [Configure the network for the DB cluster \(p. 252\)](#)
- [Additional prerequisites \(p. 255\)](#)

Configure the network for the DB cluster

You can create a Multi-AZ DB cluster only in a virtual private cloud (VPC) based on the Amazon VPC service. It must be in an AWS Region that has at least three Availability Zones. The DB subnet group that you choose for the DB cluster must cover at least three Availability Zones. This configuration ensures that each DB instance in the DB cluster is in a different Availability Zone.

To set up connectivity between your new DB cluster and an Amazon EC2 instance in the same VPC, do so when you create the DB cluster. To connect to your DB cluster from resources other than EC2 instances in the same VPC, configure the network connections manually.

Topics

- [Configure automatic network connectivity with an EC2 instance \(p. 252\)](#)
- [Configure the network manually \(p. 254\)](#)

Configure automatic network connectivity with an EC2 instance

When you create a Multi-AZ DB cluster, you can use the AWS Management Console to set up connectivity between an EC2 instance and the new DB cluster. When you do so, RDS configures your VPC and network settings automatically. The DB cluster is created in the same VPC as the EC2 instance so that the EC2 instance can access the DB cluster.

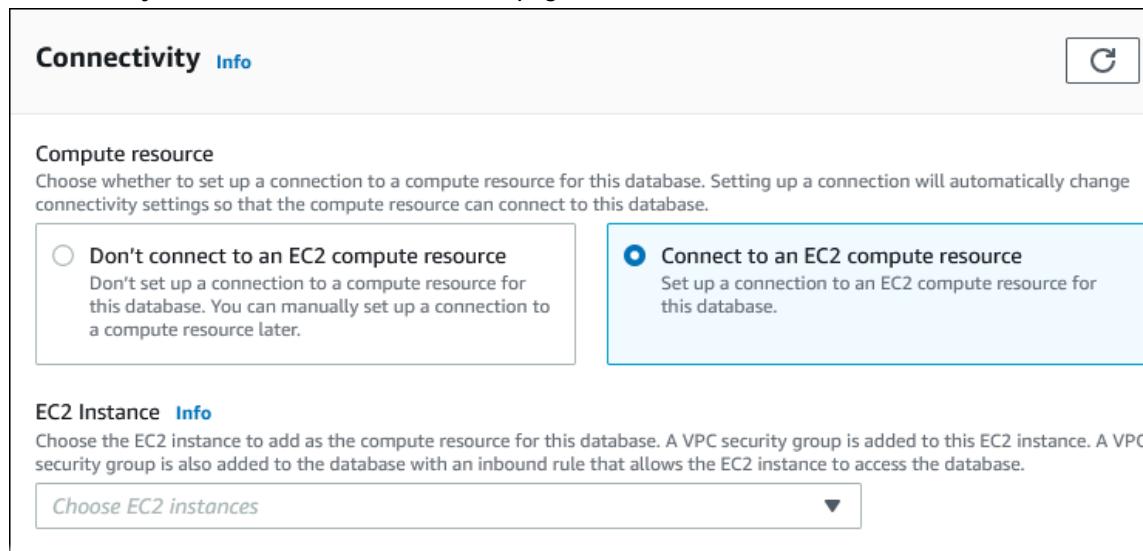

The following are requirements for connecting an EC2 instance with the DB cluster:

- The EC2 instance must exist in the AWS Region before you create the DB cluster.
If no EC2 instances exist in the AWS Region, the console provides a link to create one.
- The user who is creating the DB cluster must have permissions to perform the following operations:
 - `ec2:AssociateRouteTable`
 - `ec2:AuthorizeSecurityGroupEgress`
 - `ec2>CreateRouteTable`

- ec2:CreateSubnet
- ec2:CreateSecurityGroup
- ec2:DescribeInstances
- ec2:DescribeNetworkInterfaces
- ec2:DescribeRouteTables
- ec2:DescribeSecurityGroups
- ec2:DescribeSubnets
- ec2:ModifyNetworkInterfaceAttribute
- ec2:RevokeSecurityGroupEgress

Using this option creates a private DB cluster. The DB cluster uses a DB subnet group with only private subnets to restrict access to resources within the VPC.

To connect an EC2 instance to the DB cluster, choose **Connect to an EC2 compute resource** in the **Connectivity** section on the **Create database** page.

Connectivity [Info](#) [C](#)

Compute resource
Choose whether to set up a connection to a compute resource for this database. Setting up a connection will automatically change connectivity settings so that the compute resource can connect to this database.

Don't connect to an EC2 compute resource
Don't set up a connection to a compute resource for this database. You can manually set up a connection to a compute resource later.

Connect to an EC2 compute resource
Set up a connection to an EC2 compute resource for this database.

EC2 Instance [Info](#)
Choose the EC2 instance to add as the compute resource for this database. A VPC security group is added to this EC2 instance. A VPC security group is also added to the database with an inbound rule that allows the EC2 instance to access the database.

[Choose EC2 instances](#) ▾

When you choose **Connect to an EC2 compute resource**, RDS sets the following options automatically. You can't change these settings unless you choose not to set up connectivity with an EC2 instance by choosing **Don't connect to an EC2 compute resource**.

Console option	Automatic setting
Virtual Private Cloud (VPC)	RDS sets the VPC to the one associated with the EC2 instance.
DB subnet group	<p>A DB subnet group with a private subnet in each Availability Zone in the AWS Region is required. In some cases, a DB subnet group that meets this requirement exists. If so, RDS uses the existing DB subnet group.</p> <p>In some cases, a DB subnet group that meets this requirement doesn't exist. In these cases, RDS uses an available private subnet in each Availability Zone to create a DB subnet group using the private subnets. If a private subnet isn't available in an Availability Zone, RDS creates a private subnet in the Availability Zone. RDS then creates the DB subnet group.</p> <p>When a private subnet is available, RDS uses the route table associated with it and adds any subnets it creates to this route table. When no private</p>

Console option	Automatic setting
	subnet is available, RDS creates a route table with no internet gateway access. RDS then adds the subnets that it creates to the route table.
Public access	RDS chooses No so that the DB cluster isn't publicly accessible. For security, it is a best practice to keep the database private and make sure it isn't accessible from the internet.
VPC security group (firewall)	RDS creates a new security group that is associated with the DB cluster. The security group is named <code>rds-ec2-n</code> , where <i>n</i> is a number. This security group includes an inbound rule with the EC2 VPC security group (firewall) as the source. This security group that is associated with the DB cluster allows the EC2 instance to access the DB cluster. RDS also creates a new security group that is associated with the EC2 instance. The security group is named <code>ec2-rds-n</code> , where <i>n</i> is a number. This security group includes an outbound rule with the VPC security group of the DB cluster as the source. This security group allows the EC2 instance to send traffic to the DB cluster. You can add another new security group by choosing Create new and typing the name of the new security group. You can add existing security groups by choosing Choose existing and selecting security groups to add.
Availability Zone	RDS chooses the Availability Zone of the EC2 instance for one DB instance in the Multi-AZ DB cluster deployment. RDS randomly chooses a different Availability Zone for both of the other DB instances. The writer DB instance is created in the same Availability Zone as the EC2 instance. There is the possibility of cross Availability Zone costs if a failover occurs and the writer DB instance is in a different Availability Zone.

For more information about these settings, see [Settings for creating Multi-AZ DB clusters \(p. 258\)](#).

If you change these settings after the DB cluster is created, the changes might affect the connection between the EC2 instance and the DB cluster.

Configure the network manually

To connect to your DB cluster from resources other than EC2 instances in the same VPC, configure the network connections manually. If you use the AWS Management Console to create your Multi-AZ DB cluster, you can have Amazon RDS automatically create a VPC for you. Or you can use an existing VPC or create a new VPC for your Multi-AZ DB cluster. Your VPC must have at least one subnet in each of at least three Availability Zones for you to use it with a Multi-AZ DB cluster. For information on VPCs, see [Amazon VPCs and Amazon RDS \(p. 2103\)](#).

If you don't have a default VPC or you haven't created a VPC, and you don't plan to use the console, do the following:

- Create a VPC with at least one subnet in each of at least three of the Availability Zones in the AWS Region where you want to deploy your DB cluster. For more information, see [Working with a DB instance in a VPC \(p. 2104\)](#).
- Specify a VPC security group that authorizes connections to your DB cluster. For more information, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#) and [Controlling access with security groups \(p. 2085\)](#).

- Specify an RDS DB subnet group that defines at least three subnets in the VPC that can be used by the Multi-AZ DB cluster. For more information, see [Working with DB subnet groups \(p. 2104\)](#).

For information about limitations that apply to Multi-AZ DB clusters, see [Limitations for Multi-AZ DB clusters \(p. 136\)](#).

Additional prerequisites

Before you create your Multi-AZ DB cluster, consider the following additional prerequisites:

- To connect to AWS using AWS Identity and Access Management (IAM) credentials, your AWS account must have certain IAM policies. These grant the permissions required to perform Amazon RDS operations. For more information, see [Identity and access management for Amazon RDS \(p. 2016\)](#).

If you use IAM to access the RDS console, first sign in to the AWS Management Console with your IAM user credentials. Then go to the RDS console at <https://console.aws.amazon.com/rds/>.

- To tailor the configuration parameters for your DB cluster, specify a DB cluster parameter group with the required parameter settings. For information about creating or modifying a DB cluster parameter group, see [Working with parameter groups for Multi-AZ DB clusters \(p. 133\)](#).
- Determine the TCP/IP port number to specify for your DB cluster. The firewalls at some companies block connections to the default ports. If your company firewall blocks the default port, choose another port for your DB cluster. All DB instances in a DB cluster use the same port.

Creating a DB cluster

You can create a Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

Console

You can create a Multi-AZ DB cluster by choosing **Multi-AZ cluster** in the **Availability and durability** section.

To create a Multi-AZ DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the DB cluster.

For information about the AWS Regions that support Multi-AZ DB clusters, see [Limitations for Multi-AZ DB clusters \(p. 136\)](#).
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.

To create a Multi-AZ DB cluster, make sure that **Standard Create** is selected and **Easy Create** isn't.
5. In **Engine type**, choose **MySQL** or **PostgreSQL**.
6. For **Version**, choose the DB engine version.

For information about the DB engine versions that support Multi-AZ DB clusters, see [Limitations for Multi-AZ DB clusters \(p. 136\)](#).
7. In **Templates**, choose the appropriate template for your deployment.
8. In **Availability and durability**, choose **Multi-AZ cluster**.

Availability and durability

Deployment options [Info](#)

The deployment options below are limited to those supported by the engine you selected above.

Multi-AZ DB cluster

Creates a DB cluster with a primary DB instance and two readable standby DB instances, with each DB instance in a different Availability Zone (AZ). Provides high availability, data redundancy and increases capacity to serve read workloads.

Multi-AZ DB instance

Creates a primary DB instance and a standby DB instance in a different AZ. Provides high availability and data redundancy, but the standby DB instance doesn't support connections for read workloads.

Single DB instance

Creates a single DB instance with no standby DB instances.

9. In **DB cluster identifier**, enter the identifier for your DB cluster.
10. In **Master username**, enter your master user name, or keep the default setting.
11. Enter your master password:
 - a. In the **Settings** section, open **Credential Settings**.
 - b. If you want to specify a password, clear the **Auto generate a password** box if it is selected.
 - c. (Optional) Change the **Master username** value.
 - d. Enter the same password in **Master password** and **Confirm password**.
12. In **DB instance class**, choose a DB instance class.
13. (Optional) Set up a connection to a compute resource for this DB cluster.

You can configure connectivity between an Amazon EC2 instance and the new DB cluster during DB cluster creation. For more information, see [Configure automatic network connectivity with an EC2 instance \(p. 252\)](#).

14. For the remaining sections, specify your DB cluster settings. For information about each setting, see [Settings for creating Multi-AZ DB clusters \(p. 258\)](#).
15. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB cluster, choose **View credential details**.

To connect to the DB cluster as the master user, use the user name and password that appear.

Important

You can't view the master user password again.

16. For **Databases**, choose the name of the new DB cluster.

On the RDS console, the details for the new DB cluster appear. The DB cluster has a status of **Creating** until the DB cluster is created and ready for use. When the state changes to **Available**, you can connect to the DB cluster. Depending on the DB cluster class and storage allocated, it can take several minutes for the new DB cluster to be available.

AWS CLI

Before you create a Multi-AZ DB cluster using the AWS CLI, make sure to fulfill the required prerequisites. These include creating a VPC and an RDS DB subnet group. For more information, see [DB cluster prerequisites \(p. 252\)](#).

To create a Multi-AZ DB cluster by using the AWS CLI, call the [create-db-cluster](#) command. Specify the `--db-cluster-identifier`. For the `--engine` option, specify either `mysql` or `postgres`.

For information about each option, see [Settings for creating Multi-AZ DB clusters \(p. 258\)](#).

For information about the AWS Regions, DB engines, and DB engine versions that support Multi-AZ DB clusters, see [Limitations for Multi-AZ DB clusters \(p. 136\)](#).

The `create-db-cluster` command creates the writer DB instance for your DB cluster, and two reader DB instances. Each DB instance is in a different Availability Zone.

For example, the following command creates a MySQL 8.0 Multi-AZ DB cluster named `mysql-multi-az-db-cluster`.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
--db-cluster-identifier mysql-multi-az-db-cluster \
--engine mysql \
--engine-version 8.0.28 \
--master-user-password password \
--master-username admin \
--port 3306 \
--backup-retention-period 1 \
--db-subnet-group-name default \
--allocated-storage 4000 \
--storage-type io1 \
--iops 10000 \
--db-cluster-instance-class db.r6gd.xlarge
```

For Windows:

```
aws rds create-db-cluster ^
--db-cluster-identifier mysql-multi-az-db-cluster ^
--engine mysql ^
--engine-version 8.0.28 ^
--master-user-password password ^
--master-username admin ^
--port 3306 ^
--backup-retention-period 1 ^
--db-subnet-group-name default ^
--allocated-storage 4000 ^
--storage-type io1 ^
--iops 10000 ^
--db-cluster-instance-class db.r6gd.xlarge
```

The following command creates a PostgreSQL 13.4 Multi-AZ DB cluster named `postgresql-multi-az-db-cluster`.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
--db-cluster-identifier postgresql-multi-az-db-cluster \
--engine postgres \
--engine-version 13.4 \
--master-user-password password \
--master-username postgres \
--port 5432 \
--backup-retention-period 1 \
```

```
--db-subnet-group-name default \
--allocated-storage 4000 \
--storage-type io1 \
--iops 10000 \
--db-cluster-instance-class db.r6gd.xlarge
```

For Windows:

```
aws rds create-db-cluster ^
--db-cluster-identifier postgresql-multi-az-db-cluster ^
--engine postgres ^
--engine-version 13.4 ^
--master-user-password password ^
--master-username postgres ^
--port 5432 ^
--backup-retention-period 1 ^
--db-subnet-group-name default ^
--allocated-storage 4000 ^
--storage-type io1 ^
--iops 10000 ^
--db-cluster-instance-class db.r6gd.xlarge
```

RDS API

Before you can create a Multi-AZ DB cluster using the RDS API, make sure to fulfill the required prerequisites, such as creating a VPC and an RDS DB subnet group. For more information, see [DB cluster prerequisites \(p. 252\)](#).

To create a Multi-AZ DB cluster by using the RDS API, call the [CreateDBCluster](#) operation. Specify the `DBClusterIdentifier`. For the `Engine` parameter, specify either `mysql` or `postgresql`.

For information about each option, see [Settings for creating Multi-AZ DB clusters \(p. 258\)](#).

The `CreateDBCluster` operation creates the writer DB instance for your DB cluster, and two reader DB instances. Each DB instance is in a different Availability Zone.

Settings for creating Multi-AZ DB clusters

For details about settings that you choose when you create a Multi-AZ DB cluster, see the following table. For more information about the AWS CLI options, see [create-db-cluster](#). For more information about the RDS API parameters, see [CreateDBCluster](#).

Console setting	Setting description	CLI option and RDS API parameter
Allocated storage	<p>The amount of storage to allocate for each DB instance in your DB cluster (in gibibyte).</p> <p>For more information, see Amazon RDS DB instance storage (p. 64).</p>	CLI option: <code>--allocated-storage</code> API parameter: <code>AllocatedStorage</code>
Auto minor version upgrade	<p>Enable auto minor version upgrade to have your DB cluster receive preferred minor DB engine version upgrades automatically when they become available. Amazon RDS performs automatic minor version upgrades in the maintenance window.</p>	CLI option: <code>--auto-minor-version-upgrade</code> <code>--no-auto-minor-version-upgrade</code> API parameter: <code>AutoMinorVersionUpgrade</code>

Console setting	Setting description	CLI option and RDS API parameter
		AutoMinorVersionUpgrade
Backup retention period	The number of days that you want automatic backups of your DB cluster to be retained. For a Multi-AZ DB cluster, this value must be set to 1 or greater. For more information, see Working with backups (p. 427) .	CLI option: --backup-retention-period API parameter: BackupRetentionPeriod
Backup window	The time period during which Amazon RDS automatically takes a backup of your DB cluster. Unless you have a specific time that you want to have your database backed up, use the default of No preference . For more information, see Working with backups (p. 427) .	CLI option: --preferred-backup-window API parameter: PreferredBackupWindow
Copy tags to snapshots	This option copies any DB cluster tags to a DB snapshot when you create a snapshot. For more information, see Tagging Amazon RDS resources (p. 392) .	CLI option: -copy-tags-to-snapshot -no-copy-tags-to-snapshot RDS API parameter: CopyTagsToSnapshot
Database authentication	For Multi-AZ DB clusters, only Password authentication is supported.	None because password authentication is the default.
Database port	The port that you want to access the DB cluster through. The default port is shown. The port can't be changed after the DB cluster is created. The firewalls at some companies block connections to the default ports. If your company firewall blocks the default port, enter another port for your DB cluster.	CLI option: --port RDS API parameter: Port
DB cluster identifier	The name for your DB cluster. Name your DB clusters in the same way that you name your on-premises servers. Your DB cluster identifier can contain up to 63 alphanumeric characters, and must be unique for your account in the AWS Region you chose.	CLI option: --db-cluster-identifier RDS API parameter: DBClusterIdentifier

Console setting	Setting description	CLI option and RDS API parameter
DB cluster instance class	<p>The compute and memory capacity of each DB instance in the Multi-AZ DB cluster, for example db.r6gd.xlarge.</p> <p>If possible, choose a DB instance class large enough that a typical query working set can be held in memory. When working sets are held in memory the system can avoid writing to disk, which improves performance.</p> <p>Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see DB instance classes (p. 10).</p>	<p>CLI option: --db-cluster-instance-class</p> <p>RDS API parameter: DBClusterInstanceClass</p>
DB cluster parameter group	<p>The DB cluster parameter group that you want associated with the DB cluster.</p> <p>For more information, see Working with parameter groups for Multi-AZ DB clusters (p. 133).</p>	<p>CLI option: --db-cluster-parameter-group-name</p> <p>RDS API parameter: DBClusterParameterGroupName</p>
DB engine version	The version of database engine that you want to use.	<p>CLI option: --engine-version</p> <p>RDS API parameter: EngineVersion</p>
DB parameter group	<p>The DB instance parameter group that you want associated with the DB instances in the DB cluster.</p> <p>For more information, see Working with parameter groups for Multi-AZ DB clusters (p. 133).</p>	Not applicable. Amazon RDS associates each DB instance with the appropriate default parameter group.
DB subnet group	<p>A DB subnet group to associate with this DB cluster.</p> <p>For more information, see Working with DB subnet groups (p. 2104).</p>	<p>CLI option: --db-subnet-group-name</p> <p>RDS API parameter: DBSubnetGroupName</p>
Deletion protection	<p>Enable deletion protection to prevent your DB cluster from being deleted. If you create a production DB cluster with the console, deletion protection is turned on by default.</p> <p>For more information, see Deleting a DB instance (p. 421).</p>	<p>CLI option: --deletion-protection --no-deletion-protection</p> <p>RDS API parameter: DeletionProtection</p>

Console setting	Setting description	CLI option and RDS API parameter
Encryption	<p>Enable Encryption to turn on encryption at rest for this DB cluster.</p> <p>Encryption is turned on by default for Multi-AZ DB clusters.</p> <p>For more information, see Encrypting Amazon RDS resources (p. 2000).</p>	<p>CLI options:</p> <ul style="list-style-type: none"> --kms-key-id --storage-encrypted --no-storage-encrypted <p>RDS API parameters:</p> <ul style="list-style-type: none"> KmsKeyId StorageEncrypted
Enhanced Monitoring	<p>Enable enhanced monitoring to turn on metrics gathering in real time for the operating system that your DB cluster runs on.</p> <p>For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 600).</p>	<p>CLI options:</p> <ul style="list-style-type: none"> --monitoring-interval --monitoring-role-arn <p>RDS API parameters:</p> <ul style="list-style-type: none"> MonitoringInterval MonitoringRoleArn
Initial database name	<p>The name for the database on your DB cluster. If you don't provide a name, Amazon RDS doesn't create a database on the DB cluster for MySQL. However, it does create a database on the DB cluster for PostgreSQL. The name can't be a word reserved by the database engine. It has other constraints depending on the DB engine.</p> <p>MySQL:</p> <ul style="list-style-type: none"> • It must contain 1–64 alphanumeric characters. <p>PostgreSQL:</p> <ul style="list-style-type: none"> • It must contain 1–63 alphanumeric characters. • It must begin with a letter or an underscore. Subsequent characters can be letters, underscores, or digits (0–9). • The initial database name is <code>postgres</code>. 	<p>CLI option:</p> <ul style="list-style-type: none"> --database-name <p>RDS API parameter:</p> <ul style="list-style-type: none"> DatabaseName
Log exports	<p>The types of database log files to publish to Amazon CloudWatch Logs.</p> <p>For more information, see Publishing database logs to Amazon CloudWatch Logs (p. 683).</p>	<p>CLI option:</p> <ul style="list-style-type: none"> -enable-cloudwatch-logs-exports <p>RDS API parameter:</p> <ul style="list-style-type: none"> EnableCloudwatchLogsExports

Console setting	Setting description	CLI option and RDS API parameter
Maintenance window	<p>The 30-minute window in which pending modifications to your DB cluster are applied. If the time period doesn't matter, choose No preference.</p> <p>For more information, see The Amazon RDS maintenance window (p. 354).</p>	CLI option: --preferred-maintenance-window RDS API parameter: PreferredMaintenanceWindow
Master password	<p>The password for your master user account.</p>	CLI option: --master-user-password RDS API parameter: MasterUserPassword
Master username	<p>The name that you use as the master user name to log on to your DB cluster with all database privileges.</p> <ul style="list-style-type: none"> It can contain 1–16 alphanumeric characters and underscores. Its first character must be a letter. It can't be a word reserved by the database engine. <p>You can't change the master user name after the Multi-AZ DB cluster is created.</p> <p>For more information on privileges granted to the master user, see Master user account privileges (p. 2087).</p>	CLI option: --master-username RDS API parameter: MasterUsername

Console setting	Setting description	CLI option and RDS API parameter
Performance Insights	<p>Enable Performance Insights to monitor your DB cluster load so that you can analyze and troubleshoot your database performance.</p> <p>Choose a retention period to determine how much Performance Insights data history to keep. The retention setting in the free tier is Default (7 days). To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights (p. 548).</p> <p>Choose a master key to use to protect the key used to encrypt this database volume. Choose from the master keys in your account, or enter the key from a different account.</p> <p>For more information, see Monitoring DB load with Performance Insights on Amazon RDS (p. 543).</p>	<p>CLI options:</p> <pre>--enable-performance-insights --no-enable-performance-insights --performance-insights-retention-period --performance-insights-kms-key-id</pre> <p>RDS API parameters:</p> <pre>EnablePerformanceInsights PerformanceInsightsRetentionPeriod PerformanceInsightsKMSKeyId</pre>
Provisioned IOPS	<p>The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB cluster. This setting is available only if Provisioned IOPS (io1) is selected as the storage type.</p> <p>For more information, see Provisioned IOPS SSD storage (p. 66).</p>	<p>CLI option:</p> <pre>--iops</pre> <p>RDS API parameter:</p> <pre>Iops</pre>

Console setting	Setting description	CLI option and RDS API parameter
Public access	<p>Publicly accessible to give the DB cluster a public IP address, meaning that it's accessible outside the VPC. To be publicly accessible, the DB cluster also has to be in a public subnet in the VPC.</p> <p>Not publicly accessible to make the DB cluster accessible only from inside the VPC.</p> <p>For more information, see Hiding a DB instance in a VPC from the internet (p. 2109).</p> <p>To connect to a DB cluster from outside of its VPC, the DB cluster must be publicly accessible. Also, access must be granted using the inbound rules of the DB cluster's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 2141).</p> <p>If your DB cluster isn't publicly accessible, you can use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 2015).</p>	<p>CLI option:</p> <pre>--publicly-accessible</pre> <pre>--no-publicly-accessible</pre> <p>RDS API parameter:</p> <pre>PubliclyAccessible</pre>
Storage type	<p>The storage type for your DB cluster.</p> <p>Only Provisioned IOPS (io1) storage is supported. General Purpose (gp2) and General Purpose (gp3) storage aren't supported.</p> <p>For more information, see Amazon RDS storage types (p. 64).</p>	<p>CLI option:</p> <pre>--storage-type</pre> <p>RDS API parameter:</p> <pre>StorageType</pre>
Virtual Private Cloud (VPC)	<p>A VPC based on the Amazon VPC service to associate with this DB cluster.</p> <p>For more information, see Amazon VPC VPCs and Amazon RDS (p. 2103).</p>	For the CLI and API, you specify the VPC security group IDs.
VPC security group (firewall)	<p>The security groups to associate with the DB cluster.</p> <p>For more information, see Overview of VPC security groups (p. 2085).</p>	<p>CLI option:</p> <pre>--vpc-security-group-ids</pre> <p>RDS API parameter:</p> <pre>VpcSecurityGroupIds</pre>

Settings that don't apply when creating Multi-AZ DB clusters

The following settings in the AWS CLI command [create-db-cluster](#) and the RDS API operation [CreateDBCluster](#) don't apply to Multi-AZ DB clusters.

You also can't specify these settings for Multi-AZ DB clusters in the console.

AWS CLI setting	RDS API setting
--availability-zones	AvailabilityZones
--backtrack-window	BacktrackWindow
--character-set-name	CharacterSetName
--domain	Domain
--domain-iam-role-name	DomainIAMRoleName
--enable-global-write-forwarding --no-enable-global-write-forwarding	EnableGlobalWriteForwarding
--enable-http-endpoint --no-enable-http-endpoint	EnableHttpEndpoint
--enable-iam-database-authentication --no-enable-iam-database-authentication	EnableIAMDATABASEAuthentication
--global-cluster-identifier	GlobalClusterIdentifier
--option-group-name	OptionGroupName
--pre-signed-url	PreSignedUrl
--replication-source-identifier	ReplicationSourceIdentifier
--scaling-configuration	ScalingConfiguration

Creating Amazon RDS resources with AWS CloudFormation

Amazon RDS is integrated with AWS CloudFormation, a service that helps you to model and set up your AWS resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the AWS resources that you want (such as DB instances and DB parameter groups), and AWS CloudFormation provisions and configures those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your RDS resources consistently and repeatedly. Describe your resources once, and then provision the same resources over and over in multiple AWS accounts and Regions.

RDS and AWS CloudFormation templates

To provision and configure resources for RDS and related services, you must understand [AWS CloudFormation templates](#). Templates are formatted text files in JSON or YAML. These templates describe the resources that you want to provision in your AWS CloudFormation stacks. If you're unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer to help you get started with AWS CloudFormation templates. For more information, see [What is AWS CloudFormation Designer?](#) in the [AWS CloudFormation User Guide](#).

RDS supports creating resources in AWS CloudFormation. For more information, including examples of JSON and YAML templates for these resources, see the [RDS resource type reference](#) in the [AWS CloudFormation User Guide](#).

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:

- [AWS CloudFormation](#)
- [AWS CloudFormation User Guide](#)
- [AWS CloudFormation API Reference](#)
- [AWS CloudFormation Command Line Interface User Guide](#)

Connecting to an Amazon RDS DB instance

Before you can connect to a DB instance, you must create the DB instance. For information, see [Creating an Amazon RDS DB instance \(p. 230\)](#). After Amazon RDS provisions your DB instance, use any standard client application or utility for your DB engine to connect to the DB instance. In the connection string, specify the DNS address from the DB instance endpoint as the host parameter. Also, specify the port number from the DB instance endpoint as the port parameter.

Topics

- [Finding the connection information for an Amazon RDS DB instance \(p. 267\)](#)
- [Database authentication options \(p. 270\)](#)
- [Encrypted connections \(p. 271\)](#)
- [Scenarios for accessing a DB instance in a VPC \(p. 271\)](#)
- [Connecting to a DB instance that is running a specific DB engine \(p. 271\)](#)
- [Managing connections with RDS Proxy \(p. 272\)](#)

Finding the connection information for an Amazon RDS DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, for a MySQL DB instance, suppose that the endpoint value is `mydb.123456789012.us-east-1.rds.amazonaws.com`. In this case, the port value is 3306, and the database user is `admin`. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify `mydb.123456789012.us-east-1.rds.amazonaws.com`.
- For port, specify 3306.
- For user, specify `admin`.

The endpoint is unique for each DB instance, and the values of the port and user can vary. The following list shows the most common port for each DB engine:

- MariaDB – 3306
- Microsoft SQL Server – 1433
- MySQL – 3306
- Oracle – 1521
- PostgreSQL – 5432

To connect to a DB instance, use any client for a DB engine. For example, you might use the `mysql` utility to connect to a MariaDB or MySQL DB instance. You might use Microsoft SQL Server Management Studio to connect to a SQL Server DB instance. You might use Oracle SQL Developer to connect to an Oracle DB instance. Similarly, you might use the `psql` command line utility to connect to a PostgreSQL DB instance.

To find the connection information for a DB instance, use the AWS Management Console. You can also use the AWS Command Line Interface (AWS CLI) `describe-db-instances` command or the RDS API `DescribeDBInstances` operation.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

The screenshot shows the AWS RDS console interface. At the top, the navigation path is "RDS > Databases > mydb". Below this, the database name "mydb" is displayed in large text. A "Summary" section provides basic information: DB identifier (mydb), Role (Instance), CPU usage (2.33%), and Current activity (0 Connections). Below the summary is a tab bar with "Connectivity & security" (highlighted in orange), "Monitoring", "Logs & events", and "Configuration". The "Connectivity & security" section displays the endpoint and port details, which are circled in red. The endpoint is listed as "mydb. [REDACTED].us-east-1.rds.amazonaws.com" and the port is listed as "3306". To the right of the main content area, there is a vertical sidebar with network, availability zone, VPC, and subnet information.

Network	Available	VPC	Subnet
us-east-1	us-eas	vpc-65	default

5. If you need to find the master user name, choose the **Configuration** tab and view the **Master username** value.

AWS CLI

To find the connection information for a DB instance by using the AWS CLI, call the [describe-db-instances](#) command. In the call, query for the DB instance ID, endpoint, port, and master user name.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
--query "[].{DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername}"
```

For Windows:

```
aws rds describe-db-instances ^
--query "[].{DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername}"
```

Your output should be similar to the following.

```
[  
  [  
    "mydb",  
    "mydb.123456789012.us-east-1.rds.amazonaws.com",  
    3306,  
    "admin"  
  ],  
  [  
    "myoracledb",  
    "myoracledb.123456789012.us-east-1.rds.amazonaws.com",  
    1521,  
    "dbadmin"  
  ],  
  [  
    "mypostgresql",  
    "mypostgresql.123456789012.us-east-1.rds.amazonaws.com",  
    5432,  
    "postgresadmin"  
  ]  
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the [DescribeDBInstances](#) operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Database authentication options

Amazon RDS supports the following ways to authenticate database users:

- **Password authentication** – Your DB instance performs all administration of user accounts. You create users and specify passwords with SQL statements. The SQL statements you can use depend on your DB engine.
- **AWS Identity and Access Management (IAM) database authentication** – You don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.
- **Kerberos authentication** – You use external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

IAM database authentication and Kerberos authentication are available only for specific DB engines and versions.

For more information, see [Database authentication with Amazon RDS \(p. 1998\)](#).

Encrypted connections

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB instance. Each DB engine has its own process for implementing SSL/TLS. For more information, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 2005\)](#).

Scenarios for accessing a DB instance in a VPC

Using Amazon Virtual Private Cloud (Amazon VPC), you can launch AWS resources, such as Amazon RDS DB instances, into a virtual private cloud (VPC). When you use Amazon VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists.

A VPC security group controls access to DB instances inside a VPC. Each VPC security group rule enables a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group.

Before attempting to connect to your DB instance, configure your VPC for your use case. The following are common scenarios for accessing a DB instance in a VPC:

- **A DB instance in a VPC accessed by an Amazon EC2 instance in the same VPC** – A common use of a DB instance in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC. The EC2 instance might run a web server with an application that interacts with the DB instance.
- **A DB instance in a VPC accessed by an EC2 instance in a different VPC** – In some cases, your DB instance is in a different VPC from the EC2 instance that you're using to access it. If so, you can use VPC peering to access the DB instance.
- **A DB instance in a VPC accessed by a client application through the internet** – To access a DB instance in a VPC from a client application through the internet, you configure a VPC with a single public subnet. You also configure an internet gateway to enable communication over the internet.

To connect to a DB instance from outside of its VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see [Can't connect to Amazon RDS DB instance \(p. 2141\)](#).

- **A DB instance in a VPC accessed by a private network** – If your DB instance isn't publicly accessible, you can use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network.

For more information, see [Scenarios for accessing a DB instance in a VPC \(p. 2115\)](#).

Connecting to a DB instance that is running a specific DB engine

For information about connecting to a DB instance that is running a specific DB engine, follow the instructions for your DB engine:

- [Connecting to a DB instance running the MariaDB database engine \(p. 986\)](#)
- [Connecting to a DB instance running the Microsoft SQL Server database engine \(p. 1084\)](#)

- [Connecting to a DB instance running the MySQL database engine \(p. 1318\)](#)
- [Connecting to your Oracle DB instance \(p. 1488\)](#)
- [Connecting to a DB instance running the PostgreSQL database engine \(p. 1809\)](#)

Managing connections with RDS Proxy

You can also use Amazon RDS Proxy to manage connections to RDS for MariaDB, RDS for Microsoft SQL Server, RDS for MySQL, and RDS for PostgreSQL DB instances. RDS Proxy allows applications to pool and share database connections to improve scalability. For more information, see [Using Amazon RDS Proxy \(p. 921\)](#).

Working with option groups

Some DB engines offer additional features that make it easier to manage data and databases, and to provide additional security for your database. Amazon RDS uses option groups to enable and configure these features. An *option group* can specify features, called options, that are available for a particular Amazon RDS DB instance. Options can have settings that specify how the option works. When you associate a DB instance with an option group, the specified options and option settings are enabled for that DB instance.

Amazon RDS supports options for the following database engines:

Database engine	Relevant documentation
MariaDB	Options for MariaDB database engine (p. 1040)
Microsoft SQL Server	Options for the Microsoft SQL Server database engine (p. 1203)
MySQL	Options for MySQL DB instances (p. 1416)
Oracle	Adding options to Oracle DB instances (p. 1646)
PostgreSQL	PostgreSQL does not use options and option groups. PostgreSQL uses extensions and modules to provide additional features. For more information, see Supported PostgreSQL extension versions (p. 1807) .

Option groups overview

Amazon RDS provides an empty default option group for each new DB instance. You can't modify or delete this default option group, but any new option group that you create derives its settings from the default option group. To apply an option to a DB instance, you must do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add one or more options to the option group.
3. Associate the option group with the DB instance.

To associate an option group with a DB instance, modify the DB instance. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

Both DB instances and DB snapshots can be associated with an option group. In some cases, you might restore from a DB snapshot or perform a point-in-time restore for a DB instance. In these cases, the option group associated with the DB snapshot or DB instance is, by default, associated with the restored DB instance. You can associate a different option group with a restored DB instance. However, the new option group must contain any persistent or permanent options that were included in the original option group. Persistent and permanent options are described following.

Options require additional memory to run on a DB instance. Thus, you might need to launch a larger instance to use them, depending on your current use of your DB instance. For example, Oracle Enterprise Manager Database Control uses about 300 MB of RAM. If you enable this option for a small DB instance, you might encounter performance problems or out-of-memory errors.

Persistent and permanent options

Two types of options, persistent and permanent, require special consideration when you add them to an option group.

Persistent options can't be removed from an option group while DB instances are associated with the option group. An example of a persistent option is the TDE option for Microsoft SQL Server transparent data encryption (TDE). You must disassociate all DB instances from the option group before a persistent option can be removed from the option group. In some cases, you might restore or perform a point-in-time restore from a DB snapshot. In these cases, if the option group associated with that DB snapshot contains a persistent option, you can only associate the restored DB instance with that option group.

Permanent options, such as the TDE option for Oracle Advanced Security TDE, can never be removed from an option group. You can change the option group of a DB instance that is using the permanent option. However, the option group associated with the DB instance must include the same permanent option. In some cases, you might restore or perform a point-in-time restore from a DB snapshot. In these cases, if the option group associated with that DB snapshot contains a permanent option, you can only associate the restored DB instance with an option group with that permanent option.

For Oracle DB instances, you can copy shared DB snapshots that have the options Timezone or OLS (or both). To do so, specify a target option group that includes these options when you copy the DB snapshot. The OLS option is permanent and persistent only for Oracle DB instances running Oracle version 12.2 or higher. For more information about these options, see [Oracle time zone \(p. 1742\)](#) and [Oracle Label Security \(p. 1703\)](#).

VPC considerations

The option group associated with the DB instance is linked to the DB instance's VPC. This means that you can't use the option group assigned to a DB instance if you try to restore the instance to a different VPC. If you restore a DB instance to a different VPC, you can do one of the following:

- Assign the default option group to the DB instance.
- Assign an option group that is linked to that VPC.
- Create a new option group and assign it to the DB instance.

With persistent or permanent options, such as Oracle TDE, you must create a new option group. This option group must include the persistent or permanent option when restoring a DB instance into a different VPC.

Option settings control the behavior of an option. For example, the Oracle Advanced Security option NATIVE_NETWORK_ENCRYPTION has a setting that you can use to specify the encryption algorithm for network traffic to and from the DB instance. Some options settings are optimized for use with Amazon RDS and cannot be changed.

Mutually exclusive options

Some options are mutually exclusive. You can use one or the other, but not both at the same time. The following options are mutually exclusive:

- [Oracle Enterprise Manager Database Express \(p. 1689\)](#) and [Oracle Management Agent for Enterprise Manager Cloud Control \(p. 1693\)](#).
- [Oracle native network encryption \(p. 1711\)](#) and [Oracle Secure Sockets Layer \(p. 1722\)](#).

Creating an option group

You can create a new option group that derives its settings from the default option group. You then add one or more options to the new option group. Or, if you already have an existing option group, you can copy that option group with all of its options to a new option group. For more information, see [Copying an option group \(p. 276\)](#).

After you create a new option group, it has no options. To learn how to add options to the option group, see [Adding an option to an option group \(p. 277\)](#). After you have added the options you want, you can then associate the option group with a DB instance. This way, the options become available on the DB instance. For information about associating an option group with a DB instance, see the documentation for your engine in [Working with option groups \(p. 273\)](#).

Console

One way of creating an option group is by using the AWS Management Console.

To create a new option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:
 - a. For **Name**, type a name for the option group that is unique within your AWS account. The name can contain only letters, digits, and hyphens.
 - b. For **Description**, type a brief description of the option group. The description is used for display purposes.
 - c. For **Engine**, choose the DB engine that you want.
 - d. For **Major engine version**, choose the major version of the DB engine that you want.
5. To continue, choose **Create**. To cancel the operation instead, choose **Cancel**.

AWS CLI

To create an option group, use the AWS CLI `create-option-group` command with the following required parameters.

- `--option-group-name`
- `--engine-name`
- `--major-engine-version`
- `--option-group-description`

Example

The following example creates an option group named `testoptiongroup`, which is associated with the Oracle Enterprise Edition DB engine. The description is enclosed in quotation marks.

For Linux, macOS, or Unix:

```
aws rds create-option-group \
--option-group-name testoptiongroup \
--engine-name oracle-ee \
--major-engine-version 12.1 \
--option-group-description "Test option group"
```

For Windows:

```
aws rds create-option-group \
--option-group-name <i>testoptiongroup</i> \
--engine-name <i>oracle-ee</i> \
--major-engine-version <i>12.1</i> \
--option-group-description "<i>Test option group</i>"
```

```
aws rds create-option-group ^
--option-group-name testoptiongroup ^
--engine-name oracle-ee ^
--major-engine-version 12.1 ^
--option-group-description "Test option group"
```

RDS API

To create an option group, call the Amazon RDS API [CreateOptionGroup](#) operation. Include the following parameters:

- OptionGroupName
- EngineName
- MajorEngineVersion
- OptionGroupDescription

Copying an option group

You can use the AWS CLI or the Amazon RDS API copy an option group. Copying an option group can be convenient. An example is when you have an existing option group and want to include most of its custom parameters and values in a new option group. You can also make a copy of an option group that you use in production and then modify the copy to test other option settings.

Note

Currently, you can't copy an option group to a different AWS Region.

AWS CLI

To copy an option group, use the AWS CLI [copy-option-group](#) command. Include the following required options:

- --source-option-group-identifier
- --target-option-group-identifier
- --target-option-group-description

Example

The following example creates an option group named new-option-group, which is a local copy of the option group my-option-group.

For Linux, macOS, or Unix:

```
aws rds copy-option-group \
--source-option-group-identifier my-option-group \
--target-option-group-identifier new-option-group \
--target-option-group-description "My new option group"
```

For Windows:

```
aws rds copy-option-group ^
--source-option-group-identifier my-option-group ^
--target-option-group-identifier new-option-group ^
--target-option-group-description "My new option group"
```

RDS API

To copy an option group, call the Amazon RDS API [CopyOptionGroup](#) operation. Include the following required parameters.

- `SourceOptionGroupIdentifier`
- `TargetOptionGroupIdentifier`
- `TargetOptionGroupDescription`

Adding an option to an option group

You can add an option to an existing option group. After you have added the options you want, you can then associate the option group with a DB instance so that the options become available on the DB instance. For information about associating an option group with a DB instance, see the documentation for your specific DB engine listed at [Working with option groups \(p. 273\)](#).

Option group changes must be applied immediately in two cases:

- When you add an option that adds or updates a port value, such as the OEM option.
- When you add or remove an option group with an option that includes a port value.

In these cases, choose the **Apply Immediately** option in the console. Or you can include the `--apply-immediately` option when using the AWS CLI or set the `ApplyImmediately` parameter to true when using the Amazon RDS API. Options that don't include port values can be applied immediately, or can be applied during the next maintenance window for the DB instance.

Note

If you specify a security group as a value for an option in an option group, manage the security group by modifying the option group. You can't change or remove this security group by modifying a DB instance. Also, the security group doesn't appear in the DB instance details in the AWS Management Console or in the output for the AWS CLI command `describe-db-instances`.

Console

You can use the AWS Management Console to add an option to an option group.

To add an option to an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you want to modify, and then choose **Add option**.

Option groups (9)		
<input type="text"/> Filter subnet groups		
	Name	Description
<input type="checkbox"/>	carpcmysql	carpcmysql
<input checked="" type="checkbox"/>	carpcoracle	carpcoracle
<input type="checkbox"/>	default:mysql-5-5	Default option group for mysql 5.5
<input type="checkbox"/>	default:mysql-5-6	Default option group for mysql 5.6
<input type="checkbox"/>	default:mysql-5-7	Default option group for mysql 5.7

4. In the **Add option** window, do the following:
 - a. Choose the option that you want to add. You might need to provide additional values, depending on the option that you select. For example, when you choose the OEM option, you must also type a port value and specify a security group.
 - b. To enable the option on all associated DB instances as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No** (the default), the option is enabled for each associated DB instance during its next maintenance window.

Add Option

Option details

Option group name
carpcoracle

Option
Name of Option you want to add to this group
OEM

Port
The port number, if applicable, to use when connecting to the Option
1158

Security Groups
A list of VPC or DB Security Groups for which this Option is enabled
Choose security groups
default X

Apply Immediately [info](#)
 Yes
 No

[Cancel](#) [Add Option](#)

- When the settings are as you want them, choose **Add option**.

AWS CLI

To add an option to an option group, run the AWS CLI [add-option-to-option-group](#) command with the option that you want to add. To enable the new option immediately on all associated DB instances, include the `--apply-immediately` parameter. By default, the option is enabled for each associated DB instance during its next maintenance window. Include the following required parameter:

- `--option-group-name`

Example

The following example adds the Oracle Enterprise Manager Database Control (OEM) option to an option group named `testoptiongroup` and immediately enables it. Even if you use the default security group, you must specify that security group.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
```

```
--option-group-name testoptiongroup \
--options OptionName=OEM,Port=5500,DBSecurityGroupMemberships=default \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options OptionName=OEM,Port=5500,DBSecurityGroupMemberships=default ^
--apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP  False  oracle-ee  12.1  arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
  Test Option Group  testoptiongroup default
OPTIONS Oracle 12c EM Express  OEM      False    False   5500
DBSECURITYGROUPEMEMBERSHIPS  default authorized
```

Example

The following example adds the Oracle OEM option to an option group. It also specifies a custom port and a pair of Amazon EC2 VPC security groups to use for that port.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
--option-group-name testoptiongroup \
--options OptionName=OEM,Port=5500,VpcSecurityGroupMemberships="sg-test1,sg-test2" \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options OptionName=OEM,Port=5500,VpcSecurityGroupMemberships="sg-test1,sg-test2" ^
--apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP  False  oracle-ee  12.1  arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
  Test Option Group  testoptiongroup vpc-test
OPTIONS Oracle 12c EM Express  OEM      False    False   5500
VPCSECURITYGROUPEMEMBERSHIPS  active  sg-test1
VPCSECURITYGROUPEMEMBERSHIPS  active  sg-test2
```

Example

The following example adds the Oracle option NATIVE_NETWORK_ENCRYPTION to an option group and specifies the option settings. If no option settings are specified, default values are used.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
--option-group-name testoptiongroup \
--options '[{"OptionSettings": [{"Name": "SQLNET.ENCRYPTION_SERVER", "Value": "REQUIRED"}, {"Name": "SQLNET.ENCRYPTION_TYPES_SERVER", "Value": "AES256,AES192,DES"}]}, {"OptionName": "NATIVE_NETWORK_ENCRYPTION", "Value": "AES256,AES192,DES"}]' \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options "OptionSettings=[{"Name": "SQLNET.ENCRYPTION_SERVER", "Value": "REQUIRED"}, {"Name": "SQLNET.ENCRYPTION_TYPES_SERVER", "Value": "AES256\,AES192\,DES"}], "OptionName": "NATIVE_NETWORK_ENCRYPTION", ^
--apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP False oracle-ee 12.1 arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
Test Option Group testoptiongroup
OPTIONS Oracle Advanced Security - Native Network Encryption NATIVE_NETWORK_ENCRYPTION
    False False
OPTIONSETTINGS
    RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40
        STATIC STRING
    RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40      Specifies
        list of encryption algorithms in order of intended use
    True True SQLNET.ENCRYPTION_TYPES_SERVER AES256,AES192,DES
OPTIONSETTINGS ACCEPTED,REJECTED,REQUESTED,REQUIRED STATIC STRING REQUESTED
        Specifies the desired encryption behavior False True SQLNET.ENCRYPTION_SERVER
        REQUIRED
OPTIONSETTINGS SHA1,MD5 STATIC STRING SHA1,MD5 Specifies list of checksumming
        algorithms in order of intended use True True SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER
        SHA1,MD5
```

RDS API

To add an option to an option group using the Amazon RDS API, call the [ModifyOptionGroup](#) operation with the option that you want to add. To enable the new option immediately on all associated DB instances, include the `ApplyImmediately` parameter and set it to `true`. By default, the option is enabled for each associated DB instance during its next maintenance window. Include the following required parameter:

- `OptionGroupName`

Listing the options and option settings for an option group

You can list all the options and option settings for an option group.

Console

You can use the AWS Management Console to list all of the options and option settings for an option group.

To list the options and option settings for an option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the name of the option group to display its details. The options and option settings in the option group are listed.

AWS CLI

To list the options and option settings for an option group, use the AWS CLI `describe-option-groups` command. Specify the name of the option group whose options and settings you want to view. If you don't specify an option group name, all option groups are described.

Example

The following example lists the options and option settings for all option groups.

```
aws rds describe-option-groups
```

Example

The following example lists the options and option settings for an option group named `testoptiongroup`.

```
aws rds describe-option-groups --option-group-name testoptiongroup
```

RDS API

To list the options and option settings for an option group, use the Amazon RDS API `DescribeOptionGroups` operation. Specify the name of the option group whose options and settings you want to view. If you don't specify an option group name, all option groups are described.

Modifying an option setting

After you have added an option that has modifiable option settings, you can modify the settings at any time. If you change options or option settings in an option group, those changes are applied to all DB instances that are associated with that option group. For more information on what settings are available for the various options, see the documentation for your engine in [Working with option groups \(p. 273\)](#).

Option group changes must be applied immediately in two cases:

- When you add an option that adds or updates a port value, such as the OEM option.
- When you add or remove an option group with an option that includes a port value.

In these cases, choose the **Apply Immediately** option in the console. Or you can include the `--apply-immediately` option when using the AWS CLI or set the `ApplyImmediately` parameter to `true` when

using the RDS API. Options that don't include port values can be applied immediately, or can be applied during the next maintenance window for the DB instance.

Note

If you specify a security group as a value for an option in an option group, you manage the security group by modifying the option group. You can't change or remove this security group by modifying a DB instance. Also, the security group doesn't appear in the DB instance details in the AWS Management Console or in the output for the AWS CLI command `describe-db-instances`.

Console

You can use the AWS Management Console to modify an option setting.

To modify an option setting by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Select the option group whose option that you want to modify, and then choose **Modify option**.
4. In the **Modify option** window, from **Installed Options**, choose the option whose setting you want to modify. Make the changes that you want.
5. To enable the option as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No** (the default), the option is enabled for each associated DB instance during its next maintenance window.
6. When the settings are as you want them, choose **Modify Option**.

AWS CLI

To modify an option setting, use the AWS CLI `add-option-to-option-group` command with the option group and option that you want to modify. By default, the option is enabled for each associated DB instance during its next maintenance window. To apply the change immediately to all associated DB instances, include the `--apply-immediately` parameter. To modify an option setting, use the `--settings` argument.

Example

The following example modifies the port that the Oracle Enterprise Manager Database Control (OEM) uses in an option group named `testoptiongroup` and immediately applies the change.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
--option-group-name testoptiongroup \
--options OptionName=OEM,Port=5432,DBSecurityGroupMemberships=default \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options OptionName=OEM,Port=5432,DBSecurityGroupMemberships=default ^
--apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP  False  oracle-ee  12.1  arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
  Test Option Group  testoptiongroup
OPTIONS Oracle 12c EM Express  OEM  False  False  5432
DBSECURITYGROUPMEMBERSHIPS  default  authorized
```

Example

The following example modifies the Oracle option NATIVE_NETWORK_ENCRYPTION and changes the option settings.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
--option-group-name testoptiongroup \
--options '[{"OptionSettings": [{"Name": "SQLNET.ENCRYPTION_SERVER", "Value": "REQUIRED"}, {"Name": "SQLNET.ENCRYPTION_TYPES_SERVER", "Value": "AES256,AES192,DES,RC4_256"}]}, {"OptionName": "NATIVE_NETWORK_ENCRYPTION", "Value": "AES256,AES192,DES,RC4_256"}]' \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options "OptionSettings=[{"Name": "SQLNET.ENCRYPTION_SERVER", "Value": "REQUIRED"}, {"Name": "SQLNET.ENCRYPTION_TYPES_SERVER", "Value": "AES256\,AES192\,DES\,RC4_256"}], "OptionName": "NATIVE_NETWORK_ENCRYPTION" ^
--apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP  False  oracle-ee  12.1  arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
  Test Option Group  testoptiongroup
OPTIONS Oracle Advanced Security - Native Network Encryption  NATIVE_NETWORK_ENCRYPTION
  False  False
OPTIONSETTINGS
  RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40  STATIC
  STRING
    RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40
    Specifies list of encryption algorithms in order of intended use
      True  True  SQLNET.ENCRYPTION_TYPES_SERVER  AES256,AES192,DES,RC4_256
OPTIONSETTINGS  ACCEPTED,REJECTED,REQUESTED,REQUIRED  STATIC  STRING  REQUESTED
  Specifies the desired encryption behavior  False  True  SQLNET.ENCRYPTION_SERVER
  REQUIRED
OPTIONSETTINGS  SHA1,MD5  STATIC  STRING  SHA1,MD5  Specifies list of
  checksumming algorithms in order of intended use  True  True
  SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER  SHA1,MD5
OPTIONSETTINGS  ACCEPTED,REJECTED,REQUESTED,REQUIRED  STATIC  STRING
  REQUESTED  Specifies the desired data integrity behavior  False  True
  SQLNET.CRYPTO_CHECKSUM_SERVER  REQUESTED
```

RDS API

To modify an option setting, use the Amazon RDS API [ModifyOptionGroup](#) command with the option group and option that you want to modify. By default, the option is enabled for each associated DB instance during its next maintenance window. To apply the change immediately to all associated DB instances, include the `ApplyImmediately` parameter and set it to `true`.

Removing an option from an option group

Some options can be removed from an option group, and some cannot. A persistent option cannot be removed from an option group until all DB instances associated with that option group are disassociated. A permanent option can never be removed from an option group. For more information about what options are removable, see the documentation for your specific engine listed at [Working with option groups \(p. 273\)](#).

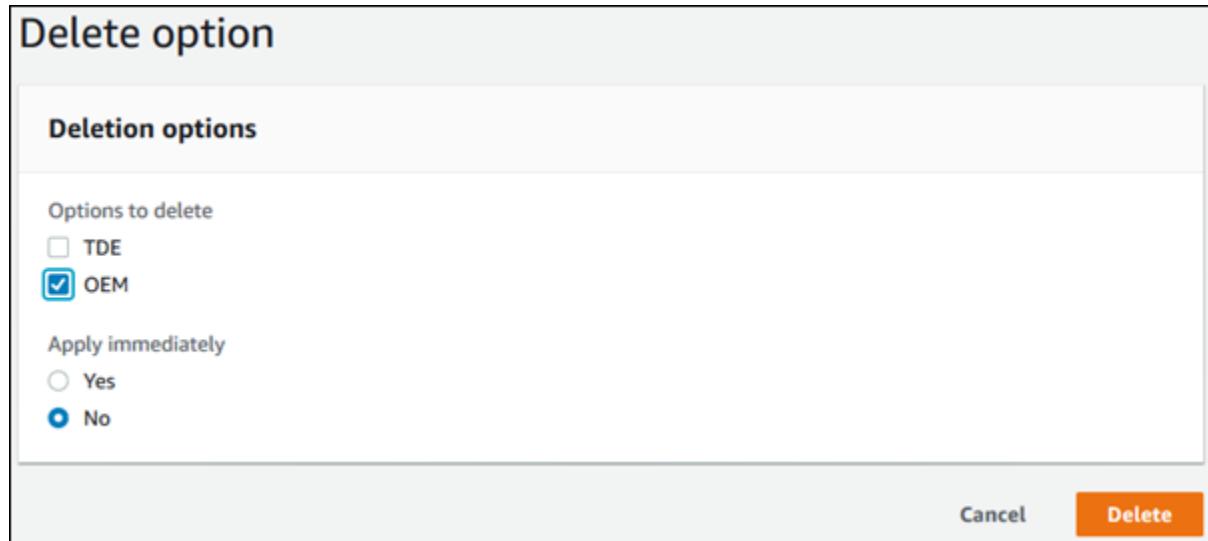

If you remove all options from an option group, Amazon RDS doesn't delete the option group. DB instances that are associated with the empty option group continue to be associated with it; they just won't have any active options. Alternatively, to remove all options from a DB instance, you can associate the DB instance with the default (empty) option group.

Console

You can use the AWS Management Console to remove an option from an option group.

To remove an option from an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Select the option group whose option you want to remove, and then choose **Delete option**.
4. In the **Delete option** window, do the following:
 - Select the check box for the option that you want to delete.
 - For the deletion to take effect as soon as you make it, for **Apply immediately**, choose **Yes**. If you choose **No** (the default), the option is deleted for each associated DB instance during its next maintenance window.

5. When the settings are as you want them, choose **Yes, Delete**.

AWS CLI

To remove an option from an option group, use the AWS CLI `remove-option-from-option-group` command with the option that you want to delete. By default, the option is removed from each associated DB instance during its next maintenance window. To apply the change immediately, include the `--apply-immediately` parameter.

Example

The following example removes the Oracle Enterprise Manager Database Control (OEM) option from an option group named `testoptiongroup` and immediately applies the change.

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
  --option-group-name testoptiongroup \
  --options OEM \
  --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
  --option-group-name testoptiongroup ^
  --options OEM ^
  --apply-immediately
```

Command output is similar to the following:

OPTIONGROUP	testoptiongroup	oracle-ee	12.1	Test option group
-------------	-----------------	-----------	------	-------------------

RDS API

To remove an option from an option group, use the Amazon RDS API `ModifyOptionGroup` action. By default, the option is removed from each associated DB instance during its next maintenance window. To apply the change immediately, include the `ApplyImmediately` parameter and set it to `true`.

Include the following parameters:

- `OptionGroupName`
- `OptionsToRemove.OptionName`

Deleting an option group

You can delete an option group that is not associated with any Amazon RDS resource. An option group can be associated with a DB instance, a manual DB snapshot, or an automated DB snapshot.

You can't delete a default option group. If you try to delete an option group that is associated with an RDS resource, an error like the following is returned.

An error occurred (InvalidOptionGroupStateFault) when calling the DeleteOptionGroup operation: The option group 'optionGroupName' cannot be deleted because it is in use.

To find the Amazon RDS resources associated with an option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the name of the option group to show its details.
4. Check the **Associated Instances and Snapshots** section for the associated Amazon RDS resources.

If a DB instance is associated with the option group, modify the DB instance to use a different option group. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

If a manual DB snapshot is associated with the option group, modify the DB snapshot to use a different option group. You can do so using the AWS CLI `modify-db-snapshot` command.

Note

You can't modify the option group of an automated DB snapshot.

Console

One way of deleting an option group is by using the AWS Management Console.

To delete an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group.
4. Choose **Delete group**.
5. On the confirmation page, choose **Delete** to finish deleting the option group, or choose **Cancel** to cancel the deletion.

AWS CLI

To delete an option group, use the AWS CLI `delete-option-group` command with the following required parameter.

- `--option-group-name`

Example

The following example deletes an option group named `testoptiongroup`.

For Linux, macOS, or Unix:

```
aws rds delete-option-group \
--option-group-name testoptiongroup
```

For Windows:

```
aws rds delete-option-group ^
--option-group-name testoptiongroup
```

RDS API

To delete an option group, call the Amazon RDS API [DeleteOptionGroup](#) operation. Include the following parameter:

- OptionGroupName

Working with parameter groups

Database parameters specify how the database is configured. For example, database parameters can specify the amount of resources, such as memory, to allocate to a database.

You manage your database configuration by associating your DB instances and Multi-AZ DB clusters with parameter groups. Amazon RDS defines parameter groups with default settings.

Important

You can define your own parameter groups with customized settings. Then you can modify your DB instances and Multi-AZ DB clusters to use your own parameter groups.

For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#). For information about modifying a Multi-AZ DB clusters, see [Modifying a Multi-AZ DB cluster \(p. 341\)](#).

Note

Some DB engines offer additional features that you can add to your database as options in an option group. For information about option groups, see [Working with option groups \(p. 273\)](#).

A *DB parameter group* acts as a container for engine configuration values that are applied to one or more DB instances.

DB cluster parameter groups only apply to Multi-AZ DB clusters. In a Multi-AZ DB cluster, the settings in the DB cluster parameter group are used for all of the DB instances in the cluster. The default DB parameter group for the DB engine and DB engine version is used for each DB instance in the DB cluster.

If you create a DB instance without specifying a DB parameter group, the DB instance uses a default DB parameter group. Likewise, if you create a Multi-AZ DB cluster without specifying a DB cluster parameter group, the DB cluster uses a default DB cluster parameter group. Each default parameter group contains database engine defaults and Amazon RDS system defaults based on the engine, compute class, and allocated storage of the instance. You can't modify the parameter settings of a default parameter group. Instead, you create your own parameter group where you choose your own parameter settings. Not all DB engine parameters can be changed in a parameter group that you create.

To use your own parameter group, you create a new parameter group and modify the parameters that you want to modify. You then modify your DB instance or DB cluster to use the new parameter group. If you update parameters within a DB parameter group, the changes apply to all DB instances that are associated with that parameter group. Likewise, if you update parameters within a Multi-AZ DB cluster parameter group, the changes apply to all Aurora clusters that are associated with that DB cluster parameter group.

You can copy an existing DB parameter group with the AWS CLI [copy-db-parameter-group](#) command. You can copy an existing DB cluster parameter group with the AWS CLI [copy-db-cluster-parameter-group](#) command. Copying a parameter group can be convenient in some cases. An example is when you want to include most of an existing DB parameter group's custom parameters and values in a new DB parameter group.

Here are some important points about working with parameters in a parameter group:

- DB instance parameters are either *static* or *dynamic*. When you change a static parameter and save the DB parameter group, the parameter change takes effect after you manually reboot the associated DB instances.

When you change a dynamic parameter, by default the parameter change is applied to your DB instance immediately, without requiring a reboot. To defer the parameter change until after an associated DB instance is rebooted, use the AWS CLI or RDS API. Set the `ApplyMethod` to `pending-reboot` for the parameter change.

When you use the AWS Management Console to change DB instance parameter values, it always uses `immediate` for the `ApplyMethod` for dynamic parameters. For static parameters, the AWS Management Console always uses `pending-reboot` for the `ApplyMethod`.

For more information about using the AWS CLI to change a parameter value, see [modify-db-parameter-group](#). For more information about using the RDS API to change a parameter value, see [ModifyDBParameterGroup](#).

Note

Using `pending-reboot` with dynamic parameters in the AWS CLI or RDS API on RDS for SQL Server DB instances generates an error. Use `apply-immediately` on RDS for SQL Server.

- DB cluster parameters are either *static* or *dynamic*. When you change a static parameter and save the DB cluster parameter group, the parameter change takes effect after you manually reboot the associated DB clusters.

When you change a dynamic parameter, by default the parameter change is applied to your DB cluster immediately, without requiring a reboot. To defer the parameter change until after an associated DB cluster is rebooted, use the AWS CLI or RDS API. Set the `ApplyMethod` to `pending-reboot` for the parameter change.

When you use the AWS Management Console to change DB cluster parameter values, it always uses `immediate` for the `ApplyMethod` for dynamic parameters. For static parameters, the console always uses `pending-reboot` for the `ApplyMethod`.

For more information about using the AWS CLI to change a parameter value, see [modify-db-cluster-parameter-group](#). For more information about using the RDS API to change a parameter value, see [ModifyDBClusterParameterGroup](#).

- If a DB instance isn't using the latest changes to its associated DB parameter group, the console shows a status of `pending-reboot` for the DB parameter group. This status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.
- When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the newly associated DB parameter group, these changes are applied immediately without a reboot. For more information about changing the DB parameter group, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).
- After you change the DB cluster parameter group associated with a Multi-AZ DB cluster, reboot the DB cluster. Doing this applies the changes to all of the DB instances in the DB cluster.

For information about rebooting a Multi-AZ DB cluster, see [Rebooting Multi-AZ DB clusters and reader DB instances \(p. 368\)](#).

- In many cases, you can specify integer and Boolean parameter values using expressions, formulas, and functions. Functions can include a mathematical log expression. However, not all parameters support expressions, formulas, and functions for parameter values. For more information, see [Specifying DB parameters \(p. 310\)](#).
- Set any parameters that relate to the character set or collation of your database in your parameter group before creating the DB instance or Multi-AZ DB cluster. Also do so before you create a database in it. This ensures that the default database and new databases use the character set and collation values that you specify. If you change character set or collation parameters, the parameter changes aren't applied to existing databases.

For some DB engines, you can change character set or collation values for an existing database using the `ALTER DATABASE` command, for example:

```
ALTER DATABASE database_name CHARACTER SET character_set_name COLLATE collation;
```

For more information about changing the character set or collation values for a database, check the documentation for your DB engine.

- Improperly setting parameters in a parameter group can have unintended adverse effects, including degraded performance and system instability. Always be cautious when modifying database parameters, and back up your data before modifying a parameter group. Try parameter group setting changes on a test DB instance or DB cluster before applying those parameter group changes to a production DB instance or DB cluster.
- To determine the supported parameters for your DB engine, view the parameters in the DB parameter group and DB cluster parameter group used by the DB instance or DB cluster. For more information, see [Viewing parameter values for a DB parameter group \(p. 301\)](#) and [Viewing parameter values for a DB cluster parameter group \(p. 309\)](#).

Topics

- [Working with DB parameter groups \(p. 291\)](#)
- [Working with DB cluster parameter groups for Multi-AZ DB clusters \(p. 302\)](#)
- [Comparing parameter groups \(p. 310\)](#)

Working with DB parameter groups

DB instances use DB parameter groups. The following sections describe configuring and managing DB instance parameter groups.

Topics

- [Creating a DB parameter group \(p. 291\)](#)
- [Associating a DB parameter group with a DB instance \(p. 293\)](#)
- [Modifying parameters in a DB parameter group \(p. 294\)](#)
- [Resetting parameters in a DB parameter group to their default values \(p. 296\)](#)
- [Copying a DB parameter group \(p. 298\)](#)
- [Listing DB parameter groups \(p. 300\)](#)
- [Viewing parameter values for a DB parameter group \(p. 301\)](#)

Creating a DB parameter group

You can create a new DB parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.

The **Create parameter group** window appears.

4. In the **Parameter group family** list, select a DB parameter group family.

5. In the **Type** list, select **DB Parameter Group**.
6. In the **Group name** box, enter the name of the new DB parameter group.
7. In the **Description** box, enter a description for the new DB parameter group.
8. Choose **Create**.

AWS CLI

To create a DB parameter group, use the AWS CLI `create-db-parameter-group` command. The following example creates a DB parameter group named *mydbparametergroup* for MySQL version 8.0 with a description of "My new parameter group."

Include the following required parameters:

- `--db-parameter-group-name`
- `--db-parameter-group-family`
- `--description`

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

Note

The output contains duplicates.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
  --db-parameter-group-name mydbparametergroup \
  --db-parameter-group-family MySQL8.0 \
  --description "My new parameter group"
```

For Windows:

```
aws rds create-db-parameter-group ^
  --db-parameter-group-name mydbparametergroup ^
  --db-parameter-group-family MySQL8.0 ^
  --description "My new parameter group"
```

This command produces output similar to the following:

```
DBPARAMETERGROUP  mydbparametergroup  mysql8.0  My new parameter group
```

RDS API

To create a DB parameter group, use the RDS API `CreateDBParameterGroup` operation.

Include the following required parameters:

- `DBParameterGroupName`
- `DBParameterGroupFamily`

- Description

Associating a DB parameter group with a DB instance

You can create your own DB parameter groups with customized settings. You can associate a DB parameter group with a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. You can do so when you create or modify a DB instance.

For information about creating a DB parameter group, see [Creating a DB parameter group \(p. 291\)](#). For information about creating a DB instance, see [Creating an Amazon RDS DB instance \(p. 230\)](#). For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

Note

When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the newly associated DB parameter group, these changes are applied immediately without a reboot.

Console

To associate a DB parameter group with a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB Instance** page appears.
4. Change the **DB parameter group** setting.
5. Choose **Continue** and check the summary of modifications.
6. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause an outage in some cases. For more information, see [Using the Apply Immediately setting \(p. 328\)](#).
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To associate a DB parameter group with a DB instance, use the AWS CLI `modify-db-instance` command with the following options:

- `--db-instance-identifier`
- `--db-parameter-group-name`

The following example associates the `mydbpg` DB parameter group with the `database-1` DB instance. The changes are applied immediately by using `--apply-immediately`. Use `--no-apply-immediately` to apply the changes during the next maintenance window. For more information, see [Using the Apply Immediately setting \(p. 328\)](#).

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier database-1 \
--db-parameter-group-name mydbpg \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier database-1 ^
--db-parameter-group-name mydbpg ^
--apply-immediately
```

RDS API

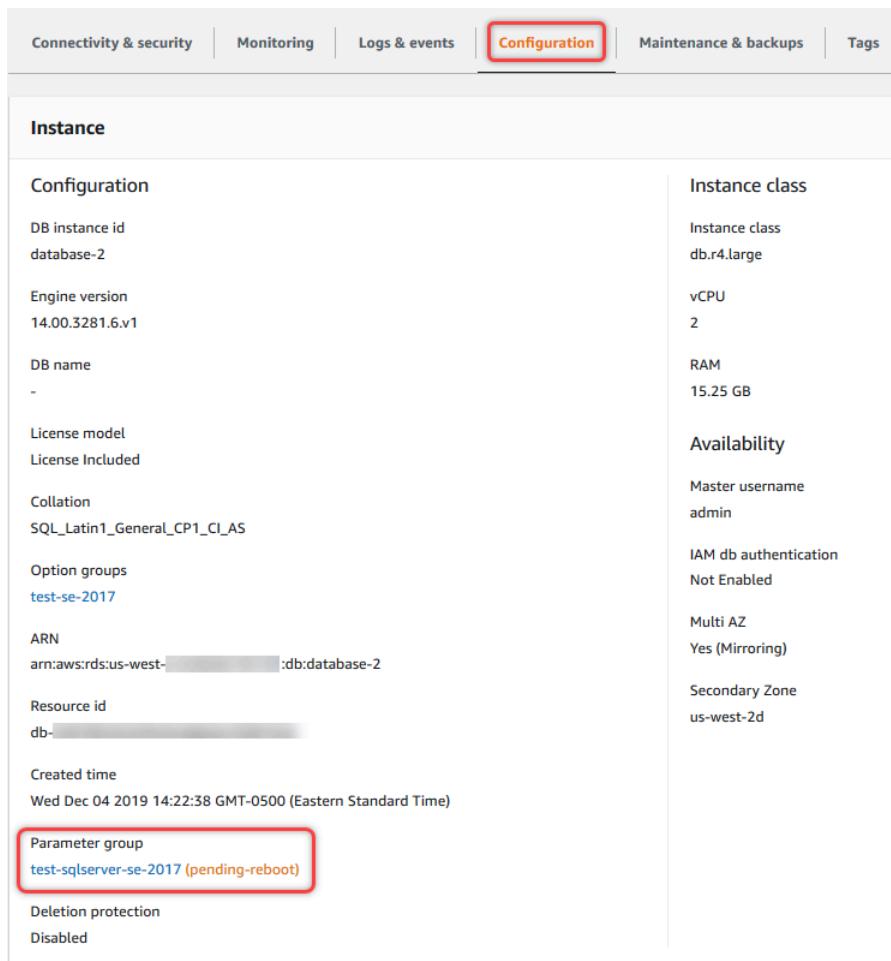

To associate a DB parameter group with a DB instance, use the RDS API [ModifyDBInstance](#) operation with the following parameters:

- `DBInstanceName`
- `DBParameterGroupName`

Modifying parameters in a DB parameter group

You can modify parameter values in a customer-created DB parameter group; you can't change the parameter values in a default DB parameter group. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the **Configuration** tab. For example, suppose that the DB instance isn't using the latest changes to its associated DB parameter group. If so, the RDS console shows the DB parameter group with a status of **pending-reboot**. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

The screenshot shows the AWS Management Console interface for an Amazon RDS instance. The top navigation bar has tabs: Connectivity & security, Monitoring, Logs & events, Configuration (which is highlighted with a red box), Maintenance & backups, and Tags. Below the tabs, the page title is "Instance". The left sidebar lists "Configuration" sections: DB instance id (database-2), Engine version (14.00.3281.6.v1), DB name (-), License model (License Included), Collation (SQL_Latin1_General_CI_AS), Option groups (test-se-2017), ARN (arn:aws:rds:us-west-2:XXXXXXXXXX:db:database-2), Resource id (db-XXXXXX), and Created time (Wed Dec 04 2019 14:22:38 GMT-0500 (Eastern Standard Time)). A red box highlights the "Parameter group" section, which contains "test-sqlserver-se-2017 (pending-reboot)". The right sidebar lists "Instance class" (db.r4.large), vCPU (2), RAM (15.25 GB), and "Availability" (Master username: admin, IAM db authentication: Not Enabled, Multi AZ: Yes (Mirroring), Secondary Zone: us-west-2d).

Console

To modify a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group that you want to modify.
4. For **Parameter group actions**, choose **Edit**.
5. Change the values of the parameters that you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

You can't change values in a default parameter group.
6. Choose **Save changes**.

AWS CLI

To modify a DB parameter group, use the AWS CLI `modify-db-parameter-group` command with the following required options:

- `--db-parameter-group-name`

- **--parameters**

The following example modifies the `max_connections` and `max_allowed_packet` values in the DB parameter group named `mydbparametergroup`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name mydbparametergroup \
  --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" \
  "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name mydbparametergroup ^
  --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" ^
  "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBPARAMETERGROUP mydbparametergroup
```

RDS API

To modify a DB parameter group, use the RDS API [ModifyDBParameterGroup](#) operation with the following required parameters:

- `DBParameterGroupName`
- `Parameters`

Resetting parameters in a DB parameter group to their default values

You can reset parameter values in a customer-created DB parameter group to their default values. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

When you use the console, you can reset specific parameters to their default values. However, you can't easily reset all of the parameters in the DB parameter group at once. When you use the AWS CLI or RDS API, you can reset specific parameters to their default values. You can also reset all of the parameters in the DB parameter group at once.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the **Configuration** tab. For example, suppose that the DB instance isn't using the latest changes to its associated DB parameter group. If so, the RDS console shows the DB parameter group with a status of **pending-reboot**. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

Configuration	Instance class
DB instance id database-2	Instance class db.r4.large
Engine version 14.00.3281.6.v1	vCPU 2
DB name -	RAM 15.25 GB
License model License Included	Availability
Collation SQL_Latin1_General_CI_AS	Master username admin
Option groups test-se-2017	IAM db authentication Not Enabled
ARN arn:aws:rds:us-west-2:123456789012:db:database-2	Multi AZ Yes (Mirroring)
Resource id db-12345678	Secondary Zone us-west-2d
Created time Wed Dec 04 2019 14:22:38 GMT-0500 (Eastern Standard Time)	
Parameter group test-sqlserver-se-2017 (pending-reboot)	
Deletion protection Disabled	

Note

In a default DB parameter group, parameters are always set to their default values.

Console

To reset parameters in a DB parameter group to their default values

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group.
4. For **Parameter group actions**, choose **Edit**.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

You can't reset values in a default parameter group.

6. Choose **Reset** and then confirm by choosing **Reset parameters**.

AWS CLI

To reset some or all of the parameters in a DB parameter group, use the AWS CLI `reset-db-parameter-group` command with the following required option: `--db-parameter-group-name`.

To reset all of the parameters in the DB parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named *mydbparametergroup* to their default values.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-parameter-group \
--db-parameter-group-name mydbparametergroup \
--reset-all-parameters
```

For Windows:

```
aws rds reset-db-parameter-group ^
--db-parameter-group-name mydbparametergroup ^
--reset-all-parameters
```

The following example resets the `max_connections` and `max_allowed_packet` options to their default values in the DB parameter group named *mydbparametergroup*.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-parameter-group \
--db-parameter-group-name mydbparametergroup \
--parameters "ParameterName=max_connections,ApplyMethod=immediate" \
"ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

For Windows:

```
aws rds reset-db-parameter-group ^
--db-parameter-group-name mydbparametergroup ^
--parameters "ParameterName=max_connections,ApplyMethod=immediate" ^
"ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBParameterGroupName mydbparametergroup
```

RDS API

To reset parameters in a DB parameter group to their default values, use the RDS API [ResetDBParameterGroup](#) command with the following required parameter: `DBParameterGroupName`.

To reset all of the parameters in the DB parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

Copying a DB parameter group

You can copy custom DB parameter groups that you create. Copying a parameter group can be convenient solution. An example is when you have created a DB parameter group and want to include

most of its custom parameters and values in a new DB parameter group. You can copy a DB parameter group by using the AWS Management Console. You can also use the AWS CLI [copy-db-parameter-group](#) command or the RDS API [CopyDBParameterGroup](#) operation.

After you copy a DB parameter group, wait at least 5 minutes before creating your first DB instance that uses that DB parameter group as the default parameter group. Doing this allows Amazon RDS to fully complete the copy action before the parameter group is used. This is especially important for parameters that are critical when creating the default database for a DB instance. An example is the character set for the default database defined by the `character_set_database` parameter. Use the **Parameter Groups** option of the [Amazon RDS console](#) or the [describe-db-parameters](#) command to verify that your DB parameter group is created.

Note

You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.

Currently, you can't copy a parameter group to a different AWS Region.

Console

To copy a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the custom parameter group that you want to copy.
4. For **Parameter group actions**, choose **Copy**.
5. In **New DB parameter group identifier**, enter a name for the new parameter group.
6. In **Description**, enter a description for the new parameter group.
7. Choose **Copy**.

AWS CLI

To copy a DB parameter group, use the AWS CLI [copy-db-parameter-group](#) command with the following required options:

- `--source-db-parameter-group-identifier`
- `--target-db-parameter-group-identifier`
- `--target-db-parameter-group-description`

The following example creates a new DB parameter group named `mygroup2` that is a copy of the DB parameter group `mygroup1`.

Example

For Linux, macOS, or Unix:

```
aws rds copy-db-parameter-group \
  --source-db-parameter-group-identifier mygroup1 \
  --target-db-parameter-group-identifier mygroup2 \
  --target-db-parameter-group-description "DB parameter group 2"
```

For Windows:

```
aws rds copy-db-parameter-group ^
```

```
--source-db-parameter-group-identifier mygroup1 ^
--target-db-parameter-group-identifier mygroup2 ^
--target-db-parameter-group-description "DB parameter group 2"
```

RDS API

To copy a DB parameter group, use the RDS API [CopyDBParameterGroup](#) operation with the following required parameters:

- `SourceDBParameterGroupIdentifier`
- `TargetDBParameterGroupIdentifier`
- `TargetDBParameterGroupDescription`

Listing DB parameter groups

You can list the DB parameter groups you've created for your AWS account.

Note

Default parameter groups are automatically created from a default parameter template when you create a DB instance for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

Console

To list all DB parameter groups for an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.

The DB parameter groups appear in a list.

AWS CLI

To list all DB parameter groups for an AWS account, use the AWS CLI [describe-db-parameter-groups](#) command.

Example

The following example lists all available DB parameter groups for an AWS account.

```
aws rds describe-db-parameter-groups
```

The command returns a response like the following:

```
DBPARAMETERGROUP default.mysql8.0      mysql8.0  Default parameter group for MySQL8.0
DBPARAMETERGROUP mydbparametergroup     mysql8.0  My new parameter group
```

The following example describes the *mydbparamgroup1* parameter group.

For Linux, macOS, or Unix:

```
aws rds describe-db-parameter-groups \
```

```
--db-parameter-group-name mydbparamgroup1
```

For Windows:

```
aws rds describe-db-parameter-groups ^
--db-parameter-group-name mydbparamgroup1
```

The command returns a response like the following:

```
DBPARAMETERGROUP mydbparametergroup1 mysql8.0 My new parameter group
```

RDS API

To list all DB parameter groups for an AWS account, use the RDS API [DescribeDBParameterGroups](#) operation.

Viewing parameter values for a DB parameter group

You can get a list of all parameters in a DB parameter group and their values.

Console

To view the parameter values for a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
The DB parameter groups appear in a list.
3. Choose the name of the parameter group to see its list of parameters.

AWS CLI

To view the parameter values for a DB parameter group, use the AWS CLI [describe-db-parameters](#) command with the following required parameter.

- `--db-parameter-group-name`

Example

The following example lists the parameters and parameter values for a DB parameter group named *mydbparametergroup*.

```
aws rds describe-db-parameters --db-parameter-group-name mydbparametergroup
```

The command returns a response like the following:

DBPARAMETER Type	Parameter Name	Parameter Value	Source	Data Type	Apply
DBPARAMETER Is Modifiable					
DBPARAMETER	allow-suspicious-udfs		engine-default	boolean	static
	false				
DBPARAMETER	auto_increment_increment		engine-default	integer	dynamic
	true				
DBPARAMETER	auto_increment_offset		engine-default	integer	dynamic
	true				

DBPARAMETER	binlog_cache_size	32768	system	integer	dynamic
DBPARAMETER	socket	/tmp/mysql.sock	system	string	static

RDS API

To view the parameter values for a DB parameter group, use the RDS API [DescribeDBParameters](#) command with the following required parameter.

- `DBParameterGroupName`

Working with DB cluster parameter groups for Multi-AZ DB clusters

Multi-AZ DB clusters use DB cluster parameter groups. The following sections describe configuring and managing DB cluster parameter groups.

Topics

- [Creating a DB cluster parameter group \(p. 302\)](#)
- [Modifying parameters in a DB cluster parameter group \(p. 304\)](#)
- [Resetting parameters in a DB cluster parameter group \(p. 305\)](#)
- [Copying a DB cluster parameter group \(p. 306\)](#)
- [Listing DB cluster parameter groups \(p. 308\)](#)
- [Viewing parameter values for a DB cluster parameter group \(p. 309\)](#)

Creating a DB cluster parameter group

You can create a new DB cluster parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

After you create a DB cluster parameter group, wait at least 5 minutes before creating a DB cluster that uses that DB cluster parameter group. Doing this allows Amazon RDS to fully create the parameter group before it is used by the new DB cluster. You can use the **Parameter groups** page in the [Amazon RDS console](#) or the `describe-db-cluster-parameters` command to verify that your DB cluster parameter group is created.

Console

To create a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.

The **Create parameter group** window appears.

4. In the **Parameter group family** list, select a DB parameter group family
5. In the **Type** list, select **DB Cluster Parameter Group**.
6. In the **Group name** box, enter the name of the new DB cluster parameter group.
7. In the **Description** box, enter a description for the new DB cluster parameter group.

8. Choose **Create**.

AWS CLI

To create a DB cluster parameter group, use the AWS CLI [create-db-cluster-parameter-group](#) command.

The following example creates a DB cluster parameter group named *mydbclusterparametergroup* for RDS for MySQL version 8.0 with a description of "My new cluster parameter group."

Include the following required parameters:

- `--db-cluster-parameter-group-name`
- `--db-parameter-group-family`
- `--description`

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

Note

The output contains duplicates.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-parameter-group \
    --db-cluster-parameter-group-name mydbclusterparametergroup \
    --db-parameter-group-family mysql8.0 \
    --description "My new cluster parameter group"
```

For Windows:

```
aws rds create-db-cluster-parameter-group ^
    --db-cluster-parameter-group-name mydbclusterparametergroup ^
    --db-parameter-group-family mysql8.0 ^
    --description "My new cluster parameter group"
```

This command produces output similar to the following:

```
{
    "DBClusterParameterGroup": {
        "DBClusterParameterGroupName": "mydbclusterparametergroup",
        "DBParameterGroupFamily": "mysql8.0",
        "Description": "My new cluster parameter group",
        "DBClusterParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:cluster-
pg:mydbclusterparametergroup2"
    }
}
```

RDS API

To create a DB cluster parameter group, use the RDS API [CreateDBClusterParameterGroup](#) action.

Include the following required parameters:

- `DBClusterParameterGroupName`
- `DBParameterGroupFamily`
- `Description`

Modifying parameters in a DB cluster parameter group

You can modify parameter values in a customer-created DB cluster parameter group. You can't change the parameter values in a default DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

Console

To modify a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group that you want to modify.
4. For **Parameter group actions**, choose **Edit**.
5. Change the values of the parameters you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

You can't change values in a default parameter group.
6. Choose **Save changes**.
7. Reboot the primary DB instance in the cluster to apply the changes to all of the DB instances in the cluster.

AWS CLI

To modify a DB cluster parameter group, use the AWS CLI `modify-db-cluster-parameter-group` command with the following required parameters:

- `--db-cluster-parameter-group-name`
- `--parameters`

The following example modifies the `server_audit_logging` and `server_audit_logs_upload` values in the DB cluster parameter group named `mydbclusterparametergroup`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
  --db-cluster-parameter-group-name mydbclusterparametergroup \
  --parameters
  "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" \
  "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
```

```
--db-cluster-parameter-group-name mydbclusterparametergroup ^
--parameters
"ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^
"ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBCLUSTERPARAMETERGROUP mydbclusterparametergroup
```

RDS API

To modify a DB cluster parameter group, use the RDS API [ModifyDBClusterParameterGroup](#) command with the following required parameters:

- `DBClusterParameterGroupName`
- `Parameters`

Resetting parameters in a DB cluster parameter group

You can reset parameters to their default values in a customer-created DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

Note

In a default DB cluster parameter group, parameters are always set to their default values.

Console

To reset parameters in a DB cluster parameter group to their default values

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group.
4. For **Parameter group actions**, choose **Edit**.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

You can't reset values in a default parameter group.
6. Choose **Reset** and then confirm by choosing **Reset parameters**.
7. Reboot the primary DB instance in the DB cluster to apply the changes to all of the DB instances in the DB cluster.

AWS CLI

To reset parameters in a DB cluster parameter group to their default values, use the AWS CLI [reset-db-cluster-parameter-group](#) command with the following required option: `--db-cluster-parameter-group-name`.

To reset all of the parameters in the DB cluster parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named `mydbparametergroup` to their default values.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group \
--db-cluster-parameter-group-name mydbparametergroup \
--reset-all-parameters
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^
--db-cluster-parameter-group-name mydbparametergroup ^
--reset-all-parameters
```

The following example resets the `server_audit_logging` and `server_audit_logs_upload` to their default values in the DB cluster parameter group named `mydbclusterparametergroup`.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group \
--db-cluster-parameter-group-name mydbclusterparametergroup \
--parameters "ParameterName=server_audit_logging,ApplyMethod=immediate" \
"ParameterName=server_audit_logs_upload,ApplyMethod=immediate"
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^
--db-cluster-parameter-group-name mydbclusterparametergroup ^
--parameters
"ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^
"ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBClusterParameterGroupName mydbclusterparametergroup
```

RDS API

To reset parameters in a DB cluster parameter group to their default values, use the RDS API [ResetDBClusterParameterGroup](#) command with the following required parameter: `DBClusterParameterGroupName`.

To reset all of the parameters in the DB cluster parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

Copying a DB cluster parameter group

You can copy custom DB cluster parameter groups that you create. Copying a parameter group is a convenient solution when you have already created a DB cluster parameter group and you want to include most of the custom parameters and values from that group in a new DB cluster parameter group. You can copy a DB cluster parameter group by using the AWS CLI [copy-db-cluster-parameter-group](#) command or the RDS API [CopyDBClusterParameterGroup](#) operation.

After you copy a DB cluster parameter group, wait at least 5 minutes before creating a DB cluster that uses that DB cluster parameter group. Doing this allows Amazon RDS to fully copy the parameter group before it is used by the new DB cluster. You can use the **Parameter groups** page in the [Amazon RDS console](#) or the `describe-db-cluster-parameters` command to verify that your DB cluster parameter group is created.

Note

You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.

Console

To copy a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the custom parameter group that you want to copy.
4. For **Parameter group actions**, choose **Copy**.
5. In **New DB parameter group identifier**, enter a name for the new parameter group.
6. In **Description**, enter a description for the new parameter group.
7. Choose **Copy**.

AWS CLI

To copy a DB cluster parameter group, use the AWS CLI `copy-db-cluster-parameter-group` command with the following required parameters:

- `--source-db-cluster-parameter-group-identifier`
- `--target-db-cluster-parameter-group-identifier`
- `--target-db-cluster-parameter-group-description`

The following example creates a new DB cluster parameter group named `mygroup2` that is a copy of the DB cluster parameter group `mygroup1`.

Example

For Linux, macOS, or Unix:

```
aws rds copy-db-cluster-parameter-group \
  --source-db-cluster-parameter-group-identifier mygroup1 \
  --target-db-cluster-parameter-group-identifier mygroup2 \
  --target-db-cluster-parameter-group-description "DB parameter group 2"
```

For Windows:

```
aws rds copy-db-cluster-parameter-group ^
  --source-db-cluster-parameter-group-identifier mygroup1 ^
  --target-db-cluster-parameter-group-identifier mygroup2 ^
  --target-db-cluster-parameter-group-description "DB parameter group 2"
```

RDS API

To copy a DB cluster parameter group, use the RDS API `CopyDBClusterParameterGroup` operation with the following required parameters:

- `SourceDBClusterParameterGroupIdentifier`
- `TargetDBClusterParameterGroupIdentifier`
- `TargetDBClusterParameterGroupDescription`

List DB cluster parameter groups

You can list the DB cluster parameter groups you've created for your AWS account.

Note

Default parameter groups are automatically created from a default parameter template when you create a DB cluster for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

Console

To list all DB cluster parameter groups for an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.

The DB cluster parameter groups appear in the list with **DB cluster parameter group** for Type.

AWS CLI

To list all DB cluster parameter groups for an AWS account, use the AWS CLI [describe-db-cluster-parameter-groups](#) command.

Example

The following example lists all available DB cluster parameter groups for an AWS account.

```
aws rds describe-db-cluster-parameter-groups
```

The following example describes the *mydbclusterparametergroup* parameter group.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameter-groups \
--db-cluster-parameter-group-name mydbclusterparametergroup
```

For Windows:

```
aws rds describe-db-cluster-parameter-groups ^
--db-cluster-parameter-group-name mydbclusterparametergroup
```

The command returns a response like the following:

```
{
  "DBClusterParameterGroups": [
    {
      "DBClusterParameterGroupName": "mydbclusterparametergroup2",
      "DBParameterGroupFamily": "mysql8.0",
```

```
        "Description": "My new cluster parameter group",
        "DBClusterParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:cluster-
pg:mydbclusterparametergroup"
    }
]
```

RDS API

To list all DB cluster parameter groups for an AWS account, use the RDS API [DescribeDBClusterParameterGroups](#) action.

Viewing parameter values for a DB cluster parameter group

You can get a list of all parameters in a DB cluster parameter group and their values.

Console

To view the parameter values for a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
The DB cluster parameter groups appear in the list with **DB cluster parameter group** for Type.
3. Choose the name of the DB cluster parameter group to see its list of parameters.

AWS CLI

To view the parameter values for a DB cluster parameter group, use the AWS CLI [describe-db-cluster-parameters](#) command with the following required parameter.

- `--db-cluster-parameter-group-name`

Example

The following example lists the parameters and parameter values for a DB cluster parameter group named *mydbclusterparametergroup*, in JSON format.

The command returns a response like the following:

```
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-
name mydbclusterparametergroup
```

```
{
    "Parameters": [
        {
            "ParameterName": "activate_all_roles_on_login",
            "ParameterValue": "0",
            "Description": "Automatically set all granted roles as active after the user has authenticated successfully.",
            "Source": "engine-default",
            "ApplyType": "dynamic",
            "DataType": "boolean",
            "AllowedValues": "0,1",
            "IsModifiable": true,
            "ApplyMethod": "pending-reboot",
```

```
        "SupportedEngineModes": [
            "provisioned"
        ]
    },
{
    "ParameterName": "allow-suspicious-udfs",
    "Description": "Controls whether user-defined functions that have only an xxx symbol for the main function can be loaded",
    "Source": "engine-default",
    "ApplyType": "static",
    "DataType": "boolean",
    "AllowedValues": "0,1",
    "IsModifiable": false,
    "ApplyMethod": "pending-reboot",
    "SupportedEngineModes": [
        "provisioned"
    ]
},
...
...
```

RDS API

To view the parameter values for a DB cluster parameter group, use the RDS API [DescribeDBClusterParameters](#) command with the following required parameter.

- `DBClusterParameterGroupName`

Comparing parameter groups

You can use the AWS Management Console to view the differences between two parameter groups.

To compare two parameter groups

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the two parameter groups that you want to compare.
4. For **Parameter group actions**, choose **Compare**.

Note

The specified parameter groups must both be DB parameter groups, or they both must be DB cluster parameter groups. This is true even when the DB engine and version are the same. For example, you can't compare an Aurora MySQL 8.0 DB parameter group and an Aurora MySQL 8.0 DB cluster parameter group.

You can compare Aurora MySQL and RDS for MySQL DB parameter groups, even for different versions, but you can't compare Aurora PostgreSQL and RDS for PostgreSQL DB parameter groups.

Specifying DB parameters

DB parameter types include the following:

- Integer
- Boolean
- String
- Long

- Double
- Timestamp
- Object of other defined data types
- Array of values of type integer, Boolean, string, long, double, timestamp, or object

You can also specify integer and Boolean parameters using expressions, formulas, and functions.

For the Oracle engine, you can use the `DBInstanceClassHugePagesDefault` formula variable to specify a Boolean DB parameter. See [DB parameter formula variables \(p. 311\)](#).

For the PostgreSQL engine, you can use an expression to specify a Boolean DB parameter. See [Boolean DB parameter expressions \(p. 313\)](#).

Contents

- [DB parameter formulas \(p. 311\)](#)
 - [DB parameter formula variables \(p. 311\)](#)
 - [DB parameter formula operators \(p. 312\)](#)
- [DB parameter functions \(p. 312\)](#)
- [Boolean DB parameter expressions \(p. 313\)](#)
- [DB parameter log expressions \(p. 314\)](#)
- [DB parameter value examples \(p. 314\)](#)

DB parameter formulas

A DB parameter formula is an expression that resolves to an integer value or a Boolean value. You enclose the expression in braces: {} . You can use a formula for either a DB parameter value or as an argument to a DB parameter function.

Syntax

```
{FormulaVariable}
{FormulaVariable*Integer}
{FormulaVariable*Integer/Integer}
{FormulaVariable/Integer}
```

DB parameter formula variables

Each formula variable returns an integer or a Boolean value. The names of the variables are case-sensitive.

AllocatedStorage

Returns an integer representing the size, in bytes, of the data volume.

DBInstanceClassHugePagesDefault

Returns a Boolean value. Currently, it's only supported for Oracle engines.

For more information, see [Turning on HugePages for an RDS for Oracle instance \(p. 1610\)](#).

DBInstanceClassMemory

Returns an integer for the number of bytes of memory available to the database process. This number is internally calculated by starting with the total amount of memory for the DB instance class. From this, the calculation subtracts memory reserved for the operating system and the RDS

processes that manage the instance. Therefore, the number is always somewhat lower than the memory figures shown in the instance class tables in [DB instance classes \(p. 10\)](#). The exact value depends on a combination of factors. These include instance class, DB engine, and whether it applies to an RDS instance or an instance that's part of an Aurora cluster.

DBInstanceVCPU

Returns an integer representing the number of virtual central processing units (vCPUs) used by Amazon RDS to manage the instance. Currently, it's only supported for the PostgreSQL engine.

EndPointPort

Returns an integer representing the port used when connecting to the DB instance.

DB parameter formula operators

DB parameter formulas support two operators: division and multiplication.

Division operator: /

Divides the dividend by the divisor, returning an integer quotient. Decimals in the quotient are truncated, not rounded.

Syntax

```
dividend / divisor
```

The dividend and divisor arguments must be integer expressions.

*Multiplication operator: **

Multiplies the expressions, returning the product of the expressions. Decimals in the expressions are truncated, not rounded.

Syntax

```
expression * expression
```

Both expressions must be integers.

DB parameter functions

You specify the arguments of DB parameter functions as either integers or formulas. Each function must have at least one argument. Specify multiple arguments as a comma-separated list. The list can't have any empty members, such as *argument1,,argument3*. Function names are case-insensitive.

IF

Returns an argument.

Currently, it's only supported for Oracle engines, and the only supported first argument is {DBInstanceClassHugePagesDefault}. For more information, see [Turning on HugePages for an RDS for Oracle instance \(p. 1610\)](#).

Syntax

```
IF(argument1, argument2, argument3)
```

Returns the second argument if the first argument evaluates to true. Returns the third argument otherwise.

GREATEST

Returns the largest value from a list of integers or parameter formulas.

Syntax

```
GREATEST(argument1, argument2,...argumentn)
```

Returns an integer.

LEAST

Returns the smallest value from a list of integers or parameter formulas.

Syntax

```
LEAST(argument1, argument2,...argumentn)
```

Returns an integer.

SUM

Adds the values of the specified integers or parameter formulas.

Syntax

```
SUM(argument1, argument2,...argumentn)
```

Returns an integer.

Boolean DB parameter expressions

A Boolean DB parameter expression resolves to a Boolean value of 1 or 0. The expression is enclosed in quotation marks.

Note

Boolean DB parameter expressions are only supported for the PostgreSQL engine.

Syntax

```
"expression operator expression"
```

Both expressions must resolve to integers. An expression can be the following:

- integer constant
- DB parameter formula
- DB parameter function
- DB parameter variable

Boolean DB parameter expressions support the following inequality operators:

The greater than operator: >

Syntax

```
"expression > expression"
```

The less than operator: <

Syntax

```
"expression < expression"
```

The greater than or equal to operators: >=, =>

Syntax

```
"expression >= expression"  
"expression => expression"
```

The less than or equal to operators: <=, ==<

Syntax

```
"expression <= expression"  
"expression ==< expression"
```

Example using a Boolean DB parameter expression

The following Boolean DB parameter expression example compares the result of a parameter formula with an integer. It does so to modify the Boolean DB parameter wal_compression for a PostgreSQL DB instance. The parameter expression compares the number of vCPUs with the value 2. If the number of vCPUs is greater than 2, then the wal_compression DB parameter is set to true.

```
aws rds modify-db-parameter-group --db-parameter-group-name group-name \  
--parameters "ParameterName=wal_compression,ParameterValue=\\"{DBInstanceVCPU} > 2\\" "
```

DB parameter log expressions

You can set an integer DB parameter value to a log expression. You enclose the expression in braces: {}.

For example:

```
{log(DBInstanceClassMemory/8187281418)*1000}
```

The log function represents log base 2. This example also uses the DBInstanceClassMemory formula variable. See [DB parameter formula variables \(p. 311\)](#).

Note

Currently, you can't specify the MySQL innodb_log_file_size parameter with any value other than an integer.

DB parameter value examples

These examples show using formulas, functions, and expressions for the values of DB parameters.

Note

DB Parameter functions are currently supported only in the console and aren't supported in the AWS CLI.

Warning

Improperly setting parameters in a DB parameter group can have unintended adverse effects. These might include degraded performance and system instability. Use caution when modifying database parameters and back up your data before modifying your DB parameter group. Try out parameter group changes on a test DB instance, created using point-in-time-restores, before applying those parameter group changes to your production DB instances.

Example using the DB parameter function GREATEST

You can specify the GREATEST function in an Oracle processes parameter. Use it to set the number of user processes to the larger of either 80 or DBInstanceClassMemory divided by 9,868,951.

```
GREATEST({DBInstanceClassMemory/9868951},80)
```

Example using the DB parameter function LEAST

You can specify the LEAST function in a MySQL max_binlog_cache_size parameter value. Use it to set the maximum cache size a transaction can use in a MySQL instance to the lesser of 1 MB or DBInstanceClass/256.

```
LEAST({DBInstanceClassMemory/256},10485760)
```

Managing an Amazon RDS DB instance

Following, you can find instructions for managing and maintaining your Amazon RDS DB instance.

- [Deleting a Multi-AZ DB cluster \(p. 424\)](#)

Stopping an Amazon RDS DB instance temporarily

Suppose that you use a DB instance intermittently, for temporary testing, or for a daily development activity. If so, you can stop your Amazon RDS DB instance temporarily to save money. While your DB instance is stopped, you are charged for provisioned storage (including Provisioned IOPS). You're also charged for backup storage, including manual snapshots and automated backups within your specified retention window. However, you're not charged for DB instance hours. For more information, see [Billing FAQs](#).

Note

In some cases, a large amount of time is required to stop a DB instance. If you want to stop your DB instance and restart it immediately, you can reboot the DB instance. For information about rebooting a DB instance, see [Rebooting a DB instance \(p. 366\)](#).

You can stop and start DB instances that are running the following engines:

- MariaDB
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL

Stopping and starting a DB instance is supported for all DB instance classes, and in all AWS Regions.

You can stop and start a DB instance whether it is configured for a single Availability Zone. Or you can do so or for Multi-AZ, for database engines that support Multi-AZ deployments. You can't stop an Amazon RDS for SQL Server DB instance in a Multi-AZ configuration.

Note

For a Multi-AZ deployment, a large amount of time might be required to stop a DB instance.

If you have at least one backup after a previous failover, then you can speed up the stop DB instance operation. To do so, perform a reboot with failover operation before stopping the DB instance.

When you stop a DB instance, the DB instance performs a normal shutdown and stops running. The status of the DB instance changes to stopping and then stopped. Occasionally, an RDS for PostgreSQL DB instance doesn't shut down cleanly. If this happens, you see that the instance goes through a recovery process when you restart it later. This is expected behavior of the database engine, intended to protect database integrity. Some memory-based statistics and counters don't retain history and are re-initialized after restart, to capture the operational workload moving forward.

At the end of the normal shutdown process, any storage volumes remain attached to the DB instance, and their data is kept. Any data stored in the RAM of the DB instance is deleted.

Stopping a DB instance removes pending actions, except for pending actions for the DB instance's option group or DB parameter group.

Automated backups aren't created while a DB instance is stopped. Backups can be retained longer than the backup retention period if a DB instance has been stopped. RDS doesn't include time spent in the stopped state when the backup retention window is calculated.

Important

You can stop a DB instance for up to seven days. If you don't manually start your DB instance after seven days, your DB instance is automatically started. This way, it doesn't fall behind any required maintenance updates.

Benefits

Stopping and starting a DB instance is faster than creating a DB snapshot, and then restoring the snapshot.

When you stop a DB instance it retains its ID, Domain Name Server (DNS) endpoint, parameter group, security group, and option group. When you start a DB instance, it has the same configuration as when you stopped it. In addition, if you stop a DB instance, Amazon RDS keeps the Amazon S3 transaction logs. This means that you can do a point-in-time restore if necessary.

Limitations

The following are some limitations to stopping and starting a DB instance:

- You can't stop a DB instance that has a read replica, or that is a read replica.
- You can't stop an Amazon RDS for SQL Server DB instance in a Multi-AZ configuration.
- You can't modify a stopped DB instance.
- You can't delete an option group that is associated with a stopped DB instance.
- You can't delete a DB parameter group that is associated with a stopped DB instance.
- In a Multi-AZ configuration, the primary and secondary Availability Zones might be switched after you start the DB instance.

Option and parameter group considerations

You can't remove persistent options (including permanent options) from an option group if there are DB instances associated with that option group. This functionality is also true of any DB instance with a state of stopping, stopped, or starting.

You can change the option group or DB parameter group that is associated with a stopped DB instance. However, the change doesn't occur until the next time you start the DB instance. If you chose to apply changes immediately, the change occurs when you start the DB instance. Otherwise the change occurs during the next maintenance window after you start the DB instance.

Public IP address

When you stop a DB instance, it retains its DNS endpoint. If you stop a DB instance that has a public IP address, Amazon RDS releases its public IP address. When the DB instance is restarted, it has a different public IP address.

Note

You should always connect to a DB instance using the DNS endpoint, not the IP address.

Stopping a DB instance temporarily

You can stop a DB using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To stop a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to stop.

3. For **Actions**, choose **Stop**.
4. (Optional) In the **Stop DB Instance** window, choose **Yes** for **Create Snapshot?** and enter the snapshot name for **Snapshot name**. Choose **Yes** if you want to create a snapshot of the DB instance before stopping it.
5. Choose **Yes, Stop Now** to stop the DB instance, or choose **Cancel** to cancel the operation.

AWS CLI

To stop a DB instance by using the AWS CLI, call the [stop-db-instance](#) command with the following option:

- `--db-instance-identifier` – the name of the DB instance.

Example

```
aws rds stop-db-instance --db-instance-identifier mydbinstance
```

RDS API

To stop a DB instance by using the Amazon RDS API, call the [StopDBInstance](#) operation with the following parameter:

- `DBInstanceIdentifier` – the name of the DB instance.

Starting an Amazon RDS DB instance that was previously stopped

You can stop your Amazon RDS DB instance temporarily to save money. After you stop your DB instance, you can restart it to begin using it again. For more details about stopping and starting DB instances, see [Stopping an Amazon RDS DB instance temporarily \(p. 317\)](#).

When you start a DB instance that you previously stopped, the DB instance retains certain information. This information is the ID, Domain Name Server (DNS) endpoint, parameter group, security group, and option group. When you start a stopped instance, you are charged a full instance hour.

Console

To start a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to start.
3. For **Actions**, choose **Start**.

AWS CLI

To start a DB instance by using the AWS CLI, call the `start-db-instance` command with the following option:

- `--db-instance-identifier` – The name of the DB instance.

Example

```
aws rds start-db-instance --db-instance-identifier mydbinstance
```

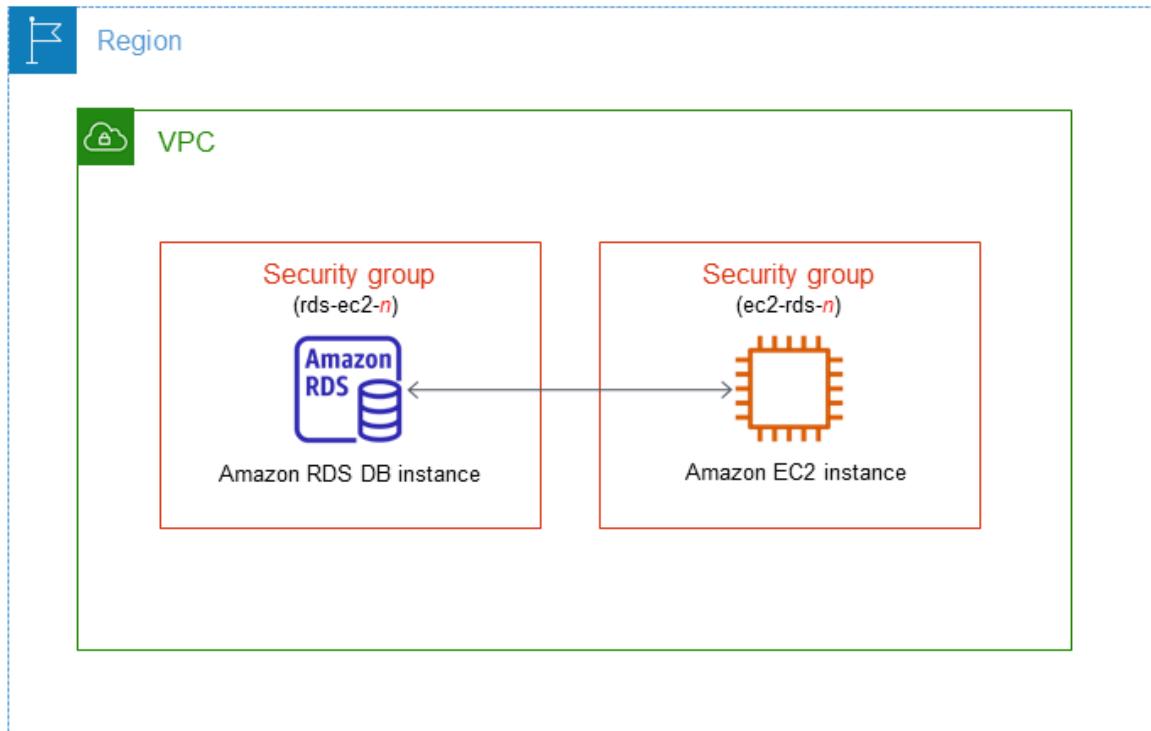

RDS API

To start a DB instance by using the Amazon RDS API, call the `StartDBInstance` operation with the following parameter:

- `DBInstanceIdentifier` – The name of the DB instance.

Connecting an EC2 instance and an RDS database automatically

You can use the RDS console to simplify setting up a connection between an EC2 instance and an RDS database. The RDS database can be a DB instance or a Multi-AZ DB cluster.

Topics

- [Overview of automatic connectivity with an EC2 instance \(p. 321\)](#)
- [Connecting an EC2 instance and an RDS database automatically \(p. 324\)](#)
- [Viewing connecting compute resources \(p. 326\)](#)

Overview of automatic connectivity with an EC2 instance

When you set up a connection between an EC2 instance and an RDS database automatically, RDS configures the VPC security group for your EC2 instance and for your RDS database.

The following are requirements for connecting an EC2 instance with an RDS database:

- The EC2 instance must exist in the same VPC as the RDS database.
If no EC2 instances exist in the same VPC, the console provides a link to create one.
- The user who is setting up connectivity must have permissions to perform the following EC2 operations:
 - `ec2:AuthorizeSecurityGroupEgress`
 - `ec2:AuthorizeSecurityGroupIngress`

- ec2:CreateSecurityGroup
- ec2:DescribeInstances
- ec2:DescribeNetworkInterfaces
- ec2:DescribeSecurityGroups
- ec2:ModifyNetworkInterfaceAttribute
- ec2:RevokeSecurityGroupEgress

If the DB instance and EC2 instance are in different Availability Zones, there is the possibility of cross Availability Zone costs.

When you set up a connection to an EC2 instance, RDS takes an action based on the current configuration of the security groups associated with the RDS database and EC2 instance, as described in the following table.

Current RDS security group configuration	Current EC2 security group configuration	RDS action
There are one or more security groups associated with the RDS database with a name that matches the pattern <code>rds-ec2-<i>n</i></code> (where <i>n</i> is a number). A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.	There are one or more security groups associated with the EC2 instance with a name that matches the pattern <code>rds-ec2-<i>n</i></code> (where <i>n</i> is a number). A security group that matches the pattern hasn't been modified. This security group has only one outbound rule with the VPC security group of the RDS database as the source.	RDS takes no action. A connection was already configured automatically between the EC2 instance and RDS database. Because a connection already exists between the EC2 instance and the RDS database, the security groups aren't modified.
Either of the following conditions apply: <ul style="list-style-type: none"> • There is no security group associated with the RDS database with a name that matches the pattern <code>rds-ec2-<i>n</i></code>. • There are one or more security groups associated with the RDS database with a name that matches the pattern <code>rds-ec2-<i>n</i></code>. However, none of these security groups can be used for the connection with the EC2 instance. A security group can't be used if it doesn't have one inbound rule with the VPC security group of the EC2 instance as the source. A security group also can't be used if it has been modified. Examples of modifications include adding a rule or changing the port of an existing rule. 	Either of the following conditions apply: <ul style="list-style-type: none"> • There is no security group associated with the EC2 instance with a name that matches the pattern <code>ec2-rds-<i>n</i></code>. • There are one or more security groups associated with the EC2 instance with a name that matches the pattern <code>ec2-rds-<i>n</i></code>. However, none of these security groups can be used for the connection with the RDS database. A security group can't be used if it doesn't have one outbound rule with the VPC security group of the RDS database as the source. A security group also can't be used if it has been modified. 	RDS action: create new security groups
There are one or more security groups associated with the RDS database with a name that matches	There are one or more security groups associated with the EC2 instance with a name that matches	RDS action: create new security groups

Current RDS security group configuration	Current EC2 security group configuration	RDS action
the pattern <code>rds-ec2-n</code> . A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.	the pattern <code>ec2-rds-n</code> . However, none of these security groups can be used for the connection with the RDS database. A security group can't be used if it doesn't have one outbound rule with the VPC security group of the RDS database as the source. A security group also can't be used if it has been modified.	
There are one or more security groups associated with the RDS database with a name that matches the pattern <code>rds-ec2-n</code> . A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.	A valid EC2 security group for the connection exists, but it is not associated with the EC2 instance. This security group has a name that matches the pattern <code>rds-ec2-n</code> . It hasn't been modified. It has only one outbound rule with the VPC security group of the RDS database as the source.	RDS action: associate EC2 security group
Either of the following conditions apply: <ul style="list-style-type: none"> • There is no security group associated with the RDS database with a name that matches the pattern <code>rds-ec2-n</code>. • There are one or more security groups associated with the RDS database with a name that matches the pattern <code>rds-ec2-n</code>. However, none of these security groups can be used for the connection with the EC2 instance. A security group can't be used if it doesn't have one inbound rule with the VPC security group of the EC2 instance as the source. A security group also can't be used if it has been modified. 	There are one or more security groups associated with the EC2 instance with a name that matches the pattern <code>rds-ec2-n</code> . A security group that matches the pattern hasn't been modified. This security group has only one outbound rule with the VPC security group of the RDS database as the source.	RDS action: create new security groups

RDS action: create new security groups

RDS takes the following actions:

- Creates a new security group that matches the pattern `rds-ec2-n`. This security group has an inbound rule with the VPC security group of the EC2 instance as the source. This security group is associated with the RDS database and allows the EC2 instance to access the RDS database.
- Creates a new security group that matches the pattern `ec2-rds-n`. This security group has an outbound rule with the VPC security group of the RDS database as the source. This security group is associated with the EC2 instance and allows the EC2 instance to send traffic to the RDS database.

RDS action: associate EC2 security group

RDS associates the valid, existing EC2 security group with the EC2 instance. This security group allows the EC2 instance to send traffic to the RDS database.

Connecting an EC2 instance and an RDS database automatically

Before setting up a connection between an EC2 instance and an RDS database, make sure you meet the requirements described in [Overview of automatic connectivity with an EC2 instance \(p. 321\)](#).

If you change these security groups after you configure connectivity, the changes might affect the connection between the EC2 instance and the RDS database.

Note

You can only set up a connection between an EC2 instance and an RDS database automatically by using the AWS Management Console. You can't set up a connection automatically with the AWS CLI or RDS API.

To connect an EC2 instance and an RDS database automatically

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the RDS database.
3. For **Actions**, choose **Set up EC2 connection**.

The **Set up EC2 connection** page appears.

The screenshot shows the 'Set up EC2 connection' page. At the top, it says 'Select EC2 instance'. Below that, under 'Database', it shows 'database-mysql'. Under 'EC2 instance', it says 'Choose the EC2 instance to connect to this database. Only EC2 instances in the same VPC as the database are shown. If no EC2 instances in the same VPC are available, you can create a new EC2 instance.' A dropdown menu is open, showing 'ec2-instance-name us-east-1a'. To the right of the dropdown is a 'Create EC2 instance' button with a plus sign icon. At the bottom right of the page are 'Cancel' and 'Continue' buttons.

4. On the **Set up EC2 connection** page, choose the EC2 instance.

If no EC2 instances exist in the same VPC, choose **Create EC2 instance** to create one. In this case, make sure the new EC2 instance is in the same VPC as the RDS database.

5. Choose **Continue**.

The **Review and confirm** page appears.

Review and confirm

Connection summary Info

You are setting up a connection between RDS database [database-mysql](#) and EC2 instance [i-123456789](#). 

To set up a connection between the database and the EC2 instance, VPC security group <name> is added to the database, and VPC security group <name> is added to the EC2 instance.

Bold indicates an addition being made to set up a connection.

Changes to RDS database: database-mysql

Attribute	Current value	New value
Security group	default	default, rds-ec2-1

Changes to EC2 instance: i-123456789

Attribute	Current value	New value
Security group	default	default, ec2-rds-1

[Cancel](#)

[Previous](#)

[Set up connection](#)

- On the **Review and confirm** page, review the changes that RDS will make to set up connectivity with the EC2 instance.

If the changes are correct, choose **Set up connection**.

If the changes aren't correct, choose **Previous** or **Cancel**.

Viewing connecting compute resources

You can use the AWS Management Console to view the compute resources that are connected to an RDS database. The resources shown include compute resource connections that were set up automatically. You can set up connectivity with compute resources automatically in the following ways:

- You can select the compute resource when you create the database.

For more information, see [Creating an Amazon RDS DB instance \(p. 230\)](#) and [Creating a Multi-AZ DB cluster \(p. 252\)](#).

- You can set up connectivity between an existing database and a compute resource.

For more information, see [Connecting an EC2 instance and an RDS database automatically \(p. 324\)](#).

The listed compute resources don't include ones that were connected to the database manually. For example, you can allow a compute resource to access a database manually by adding a rule to the VPC security group associated with the database.

For a compute resource to be listed, the following conditions must apply:

- The name of the security group associated with the compute resource matches the pattern `ec2-rds-n` (where `n` is a number).
- The security group associated with the compute resource has an outbound rule with the port range set to the port used by the RDS database.
- The security group associated with the compute resource has an outbound rule with the source set to a security group associated with the RDS database.
- The name of the security group associated with the RDS database matches the pattern `rds-ec2-n` (where `n` is a number).
- The security group associated with the RDS database has an inbound rule with the port range set to the port used by the RDS database.
- The security group associated with the RDS database has an inbound rule with the source set to a security group associated with the compute resource.

To connect an EC2 instance and an RDS database automatically

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the name of the RDS database.
3. On the **Connectivity & security** tab, view the compute resources in the **Connected compute resources**.

Connected compute resources (1) Info				
Connections to compute resources that were created automatically by RDS are shown here. Connections to compute resources that were created manually aren't shown.				
<input type="text"/> Filter by compute resources < 1 > 				
Resource identifier	Resource type	Availability zone	RDS security group	Compute resource security group
i-000000000000000000	EC2 Instance	us-west-1b	rds-ec2-1	ec2-rds-1

Modifying an Amazon RDS DB instance

You can change the settings of a DB instance to accomplish tasks such as adding additional storage or changing the DB instance class. In this topic, you can find out how to modify an Amazon RDS DB instance and learn about the settings for DB instances.

We recommend that you test any changes on a test instance before modifying a production instance. Doing this helps you to fully understand the impact of each change. Testing is especially important when upgrading database versions.

Most modifications to a DB instance you can either apply immediately or defer until the next maintenance window. Some modifications, such as parameter group changes, require that you manually reboot your DB instance for the change to take effect.

Important

Some modifications result in downtime because Amazon RDS must reboot your DB instance for the change to take effect. Review the impact to your database and applications before modifying your DB instance settings.

Console

To modify a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. Change any of the settings that you want. For information about each setting, see [Settings for DB instances \(p. 328\)](#).
5. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
6. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see [Using the Apply Immediately setting \(p. 328\)](#).
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To modify a DB instance by using the AWS CLI, call the `modify-db-instance` command. Specify the DB instance identifier and the values for the options that you want to modify. For information about each option, see [Settings for DB instances \(p. 328\)](#).

Example

The following code modifies `mydbinstance` by setting the backup retention period to 1 week (7 days). The code enables deletion protection by using `--deletion-protection`. To disable deletion protection, use `--no-deletion-protection`. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see [Using the Apply Immediately setting \(p. 328\)](#).

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier mydbinstance \  
  --backup-retention-period 7 \  
  --deletion-protection \  
  --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier mydbinstance ^  
  --backup-retention-period 7 ^  
  --deletion-protection ^  
  --no-apply-immediately
```

RDS API

To modify a DB instance by using the Amazon RDS API, call the [ModifyDBInstance](#) operation. Specify the DB instance identifier, and the parameters for the settings that you want to modify. For information about each parameter, see [Settings for DB instances \(p. 328\)](#).

Using the Apply Immediately setting

When you modify a DB instance, you can apply the changes immediately. To apply changes immediately, you choose the **Apply Immediately** option in the AWS Management Console. Or you use the `--apply-immediately` parameter when calling the AWS CLI or set the `ApplyImmediately` parameter to `true` when using the Amazon RDS API.

If you don't choose to apply changes immediately, the changes are put into the pending modifications queue. During the next maintenance window, any pending changes in the queue are applied. If you choose to apply changes immediately, your new changes and any changes in the pending modifications queue are applied.

Important

If any of the pending modifications require the DB instance to be temporarily unavailable (*downtime*), choosing the apply immediately option can cause unexpected downtime.

When you choose to apply a change immediately, any pending modifications are also applied immediately, instead of during the next maintenance window.

If you don't want a pending change to be applied in the next maintenance window, you can modify the DB instance to revert the change. You can do this by using the AWS CLI and specifying the `--apply-immediately` option.

Changes to some database settings are applied immediately, even if you choose to defer your changes. To see how the different database settings interact with the apply immediately setting, see [Settings for DB instances \(p. 328\)](#).

Settings for DB instances

In the following table, you can find details about which settings you can and can't modify. You can also find when changes can be applied and whether the changes cause downtime for your DB instance. By using Amazon RDS features such as Multi-AZ, you can minimize downtime if you later modify the DB instance. For more information, see [Multi-AZ deployments for high availability \(p. 121\)](#).

You can modify a DB instance using the console, the `modify-db-instance` CLI command, or the `ModifyDBInstance` RDS API operation.

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
<p>Allocated storage</p> <p>The storage, in gibibytes, that you want to allocate for your DB instance. You can only increase the allocated storage. You can't reduce the allocated storage.</p> <p>You can't modify the storage of some older DB instances, or DB instances restored from older DB snapshots. The Allocated storage setting is disabled in the console if your DB instance isn't eligible. You can check whether you can allocate more storage by using the CLI command describe-valid-db-instance-modifications. This command returns the valid storage options for your DB instance.</p> <p>You can't modify allocated storage if the DB instance status is storage-optimization. You also can't modify allocated storage for a DB instance if it's been modified in the last six hours.</p> <p>The maximum storage allowed depends on your DB engine and the storage type. For more information, see Amazon RDS DB instance storage (p. 64).</p>	<p>CLI option: --allocated-storage</p> <p>RDS API parameter: AllocatedStorage</p>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	<p>Downtime doesn't occur during this change. Performance might be degraded during the change.</p>	All DB engines
<p>Auto minor version upgrade</p> <p>Yes to enable your DB instance to receive preferred minor DB engine version upgrades automatically when they become available. Amazon RDS performs automatic minor version upgrades in the maintenance window. Otherwise, No.</p> <p>For more information, see Automatically upgrading the minor engine version (p. 362).</p>	<p>CLI option: --auto-minor-version-upgrade --no-auto-minor-version-upgrade</p> <p>RDS API parameter: AutoMinorVersionUpgrade</p>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Backup replication <p>Choose Enable replication to another AWS Region to create backups in an additional Region for disaster recovery.</p> <p>Then choose the Destination Region for the additional backups.</p>	Not available when modifying a DB instance. For information on enabling cross-Region backups using the AWS CLI or RDS API, see Enabling cross-Region automated backups (p. 439) .	The change is applied asynchronously, as soon as possible.	Downtime doesn't occur during this change.	Oracle, PostgreSQL, SQL Server
Backup retention period <p>The number of days that automatic backups are retained. To disable automatic backups, set the backup retention period to 0.</p> <p>For more information, see Working with backups (p. 427).</p> <p>Note If you use AWS Backup to manage your backups, this option doesn't appear. For information about AWS Backup, see the AWS Backup Developer Guide.</p>	CLI option: <code>--backup-retention-period</code> RDS API parameter: <code>BackupRetentionPeriod</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, and you change the setting from a nonzero value to another nonzero value, the change is applied asynchronously, as soon as possible. Otherwise, the change occurs during the next maintenance window.	Downtime occurs if you change from 0 to a nonzero value, or from a nonzero value to 0. This applies to both Single-AZ and Multi-AZ DB instances.	All DB engines
Backup window <p>The time range during which automated backups of your databases occur. The backup window is a start time in Universal Coordinated Time (UTC), and a duration in hours.</p> <p>For more information, see Working with backups (p. 427).</p> <p>Note If you use AWS Backup to manage your backups, this option doesn't appear. For information about AWS Backup, see the AWS Backup Developer Guide.</p>	CLI option: <code>--preferred-backup-window</code> RDS API parameter: <code>PreferredBackupWindow</code>	The change is applied asynchronously, as soon as possible.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Certificate authority The certificate that you want to use for SSL/TLS connections. For more information, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2005) .	CLI option: <code>--ca-certificate-identifier</code> RDS API parameter: <code>CACertificateIdentifier</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime occurs during this change.	All DB engines
Copy tags to snapshots If you have any DB instance tags, enable this option to copy them when you create a DB snapshot. For more information, see Tagging Amazon RDS resources (p. 392) .	CLI option: <code>--copy-tags-to-snapshot</code> or <code>--no-copy-tags-to-snapshot</code> RDS API parameter: <code>CopyTagsToSnapshot</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines
Database port The port that you want to use to access the DB instance. The port value must not match any of the port values specified for options in the option group that is associated with the DB instance. For more information, see Connecting to an Amazon RDS DB instance (p. 267) .	CLI option: <code>--db-port-number</code> RDS API parameter: <code>DBPortNumber</code>	The change occurs immediately. This setting ignores the apply immediately setting.	The DB instance is rebooted immediately.	All DB engines
DB engine version The version of the DB engine that you want to use. Before you upgrade your production DB instance, we recommend that you test the upgrade process on a test DB instance. Doing this helps verify its duration and validate your applications. For more information, see Upgrading a DB instance engine version (p. 360) .	CLI option: <code>--engine-version</code> RDS API parameter: <code>EngineVersion</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime occurs during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
DB instance class The DB instance class that you want to use. For more information, see DB instance classes (p. 10) .	CLI option: <code>--db-instance-class</code> RDS API parameter: <code>DBInstanceClass</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime occurs during this change.	All DB engines
DB instance identifier The new DB instance identifier. This value is stored as a lowercase string. For more information about the effects of renaming a DB instance, see Renaming a DB instance (p. 364) .	CLI option: <code>--new-db-instance-identifier</code> RDS API parameter: <code>NewDBInstanceIdentifier</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime occurs during this change.	All DB engines
DB parameter group The DB parameter group that you want associated with the DB instance. For more information, see Working with parameter groups (p. 289) .	CLI option: <code>--db-parameter-group-name</code> RDS API parameter: <code>DBParameterGroupName</code>	The parameter group change occurs immediately.	Downtime doesn't occur during this change. When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the newly associated DB parameter group, these changes are applied immediately without a reboot. For more information, see Working with parameter groups (p. 289) and Rebooting a DB instance (p. 366) .	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Deletion protection Enable deletion protection to prevent your DB instance from being deleted. For more information, see Deleting a DB instance (p. 421) .	CLI option: <code>--deletion-protection --no-deletion-protection</code> RDS API parameter: <code>DeletionProtection</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines
Enhanced Monitoring Enable Enhanced Monitoring to enable gathering metrics in real time for the operating system that your DB instance runs on. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 600) .	CLI option: <code>--monitoring-interval and --monitoring-role-arn</code> RDS API parameter: <code>MonitoringInterval</code> and <code>MonitoringRoleArn</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines
IAM DB authentication Enable IAM DB authentication to authenticate database users through IAM users and roles. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2048) .	CLI option: <code>--enable-iam-database-authentication --no-enable-iam-database-authentication</code> RDS API parameter: <code>EnableIAMDatabaseAuthentication</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime doesn't occur during this change.	Only MariaDB, MySQL, and PostgreSQL
Kerberos authentication Choose the Active Directory to move the DB instance to. The directory must exist prior to this operation. If a directory is already selected, you can specify None to remove the DB instance from its current directory. For more information, see Kerberos authentication (p. 1999) .	CLI option: <code>--domain and --domain-iam-role-name</code> RDS API parameter: <code>Domain</code> and <code>DomainIAMRoleName</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	A brief downtime occurs during this change.	Only Microsoft SQL Server, MySQL, Oracle, and PostgreSQL

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
<p>License model</p> <p>Choose bring-your-own-license to use your license for Oracle.</p> <p>Choose license-included to use the general license agreement for Microsoft SQL Server or Oracle.</p> <p>For more information, see Licensing Microsoft SQL Server on Amazon RDS (p. 1083) and RDS for Oracle licensing options (p. 1474).</p>	CLI option: <code>--license-model</code> RDS API parameter: <code>LicenseModel</code>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	Downtime occurs during this change.	Only Microsoft SQL Server and Oracle
<p>Log exports</p> <p>The types of database log files to publish to Amazon CloudWatch Logs.</p> <p>For more information, see Publishing database logs to Amazon CloudWatch Logs (p. 683).</p>	CLI option: <code>--cloudwatch-logs-export-configuration</code> RDS API parameter: <code>CloudwatchLogsExportConfiguration</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines
<p>Maintenance window</p> <p>The time range during which system maintenance occurs. System maintenance includes upgrades, if applicable. The maintenance window is a start time in Universal Coordinated Time (UTC), and a duration in hours.</p> <p>If you set the window to the current time, there must be at least 30 minutes between the current time and the end of the window. This timing helps ensure that any pending changes are applied.</p> <p>For more information, see The Amazon RDS maintenance window (p. 354).</p>	CLI option: <code>--preferred-maintenance-window</code> RDS API parameter: <code>PreferredMaintenanceWindow</code>	The change occurs immediately. This setting ignores the apply immediately setting.	If there are one or more pending actions that cause downtime, and the maintenance window is changed to include the current time, those pending actions are applied immediately and downtime occurs.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Multi-AZ deployment <p>Yes to deploy your DB instance in multiple Availability Zones. Otherwise, No.</p> <p>For more information, see Multi-AZ deployments for high availability (p. 121).</p>	CLI option: <code>--multi-az --no-multi-az</code> RDS API parameter: <code>MultiAZ</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime doesn't occur during this change. However, there is a possible performance impact. For more information, see Modifying a DB instance to be a Multi-AZ DB instance deployment (p. 123) .	All DB engines
Network type <p>The IP addressing protocols supported by the DB instance.</p> <p>IPv4 to specify that resources can communicate with the DB instance only over the Internet Protocol version 4 (IPv4) addressing protocol.</p> <p>Dual-stack mode to specify that resources can communicate with the DB instance over IPv4, Internet Protocol version 6 (IPv6), or both. Use dual-stack mode if you have any resources that must communicate with your DB instance over the IPv6 addressing protocol. Also, make sure that you associate an IPv6 CIDR block with all subnets in the DB subnet group that you specify.</p> <p>For more information, see Amazon RDS IP addressing (p. 2105).</p>	CLI option: <code>--network-type</code> RDS API parameter: <code>NetworkType</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime is possible during this change.	All DB engines
New master password <p>The password for your master user. The password must contain 8–41 alphanumeric characters.</p>	CLI option: <code>--master-user-password</code> RDS API parameter: <code>MasterUserPassword</code>	The change is applied asynchronously, as soon as possible. This setting ignores the <code>apply_immediately</code> setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Option group The option group that you want associated with the DB instance. For more information, see Working with option groups (p. 273) .	CLI option: <code>--option-group-name</code> RDS API parameter: <code>OptionGroupName</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime doesn't occur during this change.	All DB engines
Performance Insights Enable Performance Insights to monitor your DB instance load so that you can analyze and troubleshoot your database performance. Performance Insights isn't available for some DB engine versions and DB instance classes. The Performance Insights section doesn't appear in the console if it isn't available for your DB instance. For more information, see Monitoring DB load with Performance Insights on Amazon RDS (p. 543) and Amazon RDS DB engine, Region, and instance class support for Performance Insights (p. 547) .	CLI option: <code>--enable-performance-insights --no-enable-performance-insights</code> RDS API parameter: <code>EnablePerformanceInsights</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines
Performance Insights AWS KMS key The AWS KMS key identifier for the AWS KMS key for encryption of Performance Insights data. The key identifier is the Amazon Resource Name (ARN), AWS KMS key identifier, or the key alias for the KMS key. For more information, see Turning Performance Insights on and off (p. 549) .	CLI option: <code>--performance-insights-kms-key-id</code> RDS API parameter: <code>PerformanceInsightsKMSKeyId</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
<p>Performance Insights Retention period</p> <p>The amount of time, in days, to retain Performance Insights data. The retention setting in the free tier is Default (7 days). To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights (p. 548).</p> <p>For more information, see Turning Performance Insights on and off (p. 549).</p>	<p>CLI option: <code>--performance-insights-retention-period</code></p> <p>RDS API parameter: <code>PerformanceInsightsRetentionPeriod</code></p>	<p>The change occurs immediately. This setting ignores the <code>apply immediately</code> setting.</p>	<p>Downtime doesn't occur during this change.</p>	All DB engines
<p>Processor features</p> <p>The number of CPU cores and the number of threads per core for the DB instance class of the DB instance.</p> <p>For more information, see Configuring the processor for a DB instance class (p. 42).</p>	<p>CLI option: <code>--processor-features</code> and <code>--use-default-processor-features</code> <code>--no-use-default-processor-features</code></p> <p>RDS API parameter: <code>ProcessorFeatures</code> and <code>UseDefaultProcessorFeatures</code></p>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	<p>Downtime occurs during this change.</p>	Only Oracle
<p>Provisioned IOPS</p> <p>The Provisioned IOPS (I/O operations per second) value for the DB instance. This setting is available only if you choose one of the following for Storage type:</p> <ul style="list-style-type: none"> • General purpose SSD (gp3) • Provisioned IOPS SSD (io1) <p>For more information, see Provisioned IOPS SSD storage (p. 66) and Amazon RDS DB instance storage (p. 64).</p>	<p>CLI option: <code>--iops</code></p> <p>RDS API parameter: <code>Iops</code></p>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	<p>Downtime doesn't occur during this change.</p>	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
<p>Public access</p> <p>Publicly accessible to give the DB instance a public IP address, meaning that it's accessible outside the VPC. To be publicly accessible, the DB instance also has to be in a public subnet in the VPC.</p> <p>Not publicly accessible to make the DB instance accessible only from inside the VPC.</p> <p>For more information, see Hiding a DB instance in a VPC from the internet (p. 2109).</p> <p>To connect to a DB instance from outside its VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group. In addition, other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 2141).</p> <p>If your DB instance isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 2015).</p>	<p>CLI option: <code>--publicly-accessible --no-publicly-accessible</code></p> <p>RDS API parameter: <code>PubliclyAccessible</code></p>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines
<p>Security group</p> <p>The VPC security group that you want associated with the DB instance.</p> <p>For more information, see Controlling access with security groups (p. 2085).</p>	<p>CLI option: <code>--vpc-security-group-ids</code></p> <p>RDS API parameter: <code>VpcSecurityGroupIds</code></p>	The change is applied asynchronously, as soon as possible. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
<p>Storage autoscaling</p> <p>Enable storage autoscaling to enable Amazon RDS to automatically increase storage when needed to avoid having your DB instance run out of storage space.</p> <p>Use Maximum storage threshold to set the upper limit for Amazon RDS to automatically increase storage for your DB instance. The default is 1,000 GiB.</p> <p>For more information, see Managing capacity automatically with Amazon RDS storage autoscaling (p. 412).</p>	<p>CLI option: <code>--max-allocated-storage</code></p> <p>RDS API parameter: <code>MaxAllocatedStorage</code></p>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines
<p>Storage throughput</p> <p>The new storage throughput value for the DB instance. This setting is available only if you choose General purpose SSD (gp3) for Storage type.</p> <p>For more information, see Amazon RDS DB instance storage (p. 64).</p>	<p>CLI option: <code>--storage-throughput</code></p> <p>RDS API parameter: <code>StorageThroughput</code></p>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Storage type The storage type that you want to use. If you choose General Purpose SSD (gp3) , you can provision additional Provisioned IOPS and Storage throughput under Advanced settings . If you choose Provisioned IOPS SSD (io1) , enter the Provisioned IOPS value. After Amazon RDS begins to modify your DB instance to change the storage size or type, you can't submit another request to change the storage size, performance, or type for six hours. For more information, see Amazon RDS storage types (p. 64) .	CLI option: <code>--storage-type</code> RDS API parameter: <code>StorageType</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	The following changes all result in a brief downtime while the process starts. After that, you can use your database normally while the change takes place. <ul style="list-style-type: none"> • From General Purpose (SSD) or Provisioned IOPS (SSD) to Magnetic. • From Magnetic to General Purpose (SSD) or Provisioned IOPS (SSD). 	All DB engines
DB subnet group The DB subnet group for the DB instance. You can use this setting to move your DB instance to a different VPC. For more information, see Amazon VPC VPCs and Amazon RDS (p. 2103) .	CLI option: <code>--db-subnet-group-name</code> RDS API parameter: <code>DBSubnetGroupName</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime occurs during this change.	All DB engines

Modifying a Multi-AZ DB cluster

A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower latency when compared to Multi-AZ deployments. For more information about Multi-AZ DB clusters, see [Multi-AZ DB cluster deployments \(p. 127\)](#).

You can modify a Multi-AZ DB cluster to change its settings. You can also perform operations on a Multi-AZ DB cluster, such as taking a snapshot of it. However, you can't modify the DB instances in a Multi-AZ DB cluster, and the only supported operation is rebooting a DB instance.

Note

Multi-AZ DB clusters are supported only for the MySQL and PostgreSQL DB engines.

You can modify a Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To modify a Multi-AZ DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the Multi-AZ DB cluster that you want to modify.
3. Choose **Modify**. The **Modify DB cluster** page appears.
4. Change any of the settings that you want. For information about each setting, see [Settings for modifying Multi-AZ DB clusters \(p. 342\)](#).
5. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
6. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see [Using the Apply Immediately setting \(p. 342\)](#).
7. On the confirmation page, review your changes. If they're correct, choose **Modify DB cluster** to save your changes.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To modify a Multi-AZ DB cluster by using the AWS CLI, call the `modify-db-cluster` command. Specify the DB cluster identifier and the values for the options that you want to modify. For information about each option, see [Settings for modifying Multi-AZ DB clusters \(p. 342\)](#).

Example

The following code modifies `my-multi-az-dbcluster` by setting the backup retention period to 1 week (7 days). The code turns on deletion protection by using `--deletion-protection`. To turn off deletion protection, use `--no-deletion-protection`. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see [Using the Apply Immediately setting \(p. 342\)](#).

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier my-multi-az-dbcluster \
    --backup-retention-period 7 \
```

```
--deletion-protection \
--no-apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^
--db-cluster-identifier my-multi-az-dbcluster ^
--backup-retention-period 7 ^
--deletion-protection ^
--no-apply-immediately
```

RDS API

To modify a Multi-AZ DB cluster by using the Amazon RDS API, call the [ModifyDBCluster](#) operation. Specify the DB cluster identifier, and the parameters for the settings that you want to modify. For information about each parameter, see [Settings for modifying Multi-AZ DB clusters \(p. 342\)](#).

Using the Apply Immediately setting

When you modify a Multi-AZ DB cluster, you can apply the changes immediately. To apply changes immediately, you choose the **Apply Immediately** option in the AWS Management Console. Or you use the `--apply-immediately` option when calling the AWS CLI or set the `ApplyImmediately` parameter to true when using the Amazon RDS API.

If you don't choose to apply changes immediately, the changes are put into the pending modifications queue. During the next maintenance window, any pending changes in the queue are applied. If you choose to apply changes immediately, your new changes and any changes in the pending modifications queue are applied.

Important

If any of the pending modifications require the DB cluster to be temporarily unavailable (*downtime*), choosing the apply immediately option can cause unexpected downtime.

When you choose to apply a change immediately, any pending modifications are also applied immediately, instead of during the next maintenance window.

If you don't want a pending change to be applied in the next maintenance window, you can modify the DB instance to revert the change. You can do this by using the AWS CLI and specifying the `--apply-immediately` option.

Changes to some database settings are applied immediately, even if you choose to defer your changes. To see how the different database settings interact with the apply immediately setting, see [Settings for modifying Multi-AZ DB clusters \(p. 342\)](#).

Settings for modifying Multi-AZ DB clusters

For details about settings that you can use to modify a Multi-AZ DB cluster, see the following table. For more information about the AWS CLI options, see [modify-db-cluster](#). For more information about the RDS API parameters, see [ModifyDBCluster](#).

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes
Allocated storage	The amount of storage to allocate for each DB instance in your DB cluster (in gibibytes).	CLI option: <code>--allocated-storage</code> API parameter:	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change	Downtime doesn't occur during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes
	For more information, see Amazon RDS DB instance storage (p. 64) .	AllocatedStorage	immediately, it occurs during the next maintenance window.	
Auto minor version upgrade	Enable auto minor version upgrade to have your DB cluster receive preferred minor DB engine version upgrades automatically when they become available. Amazon RDS performs automatic minor version upgrades in the maintenance window.	CLI option: --auto-minor-version-upgrade --no-auto-minor-version-upgrade API parameter: AutoMinorVersionUpgrade	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.
Backup retention period	The number of days that you want automatic backups of your DB cluster to be retained. For any nontrivial DB cluster, set this value to 1 or greater. For more information, see Working with backups (p. 427) .	CLI option: --backup-retention-period API parameter: BackupRetentionPeriod	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, and you change the setting from a nonzero value to another nonzero value, the change is applied asynchronously, as soon as possible. Otherwise, the change occurs during the next maintenance window.	Downtime occurs if you change from 0 to a nonzero value, or from a nonzero value to 0.
Backup window	The time period during which Amazon RDS automatically takes a backup of your DB cluster. Unless you have a specific time that you want to have your database backed up, use the default of No preference . For more information, see Working with backups (p. 427) .	CLI option: --preferred-backup-window API parameter: PreferredBackupWindow	The change is applied asynchronously, as soon as possible.	Downtime doesn't occur during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes
Copy tags to snapshots	<p>This option copies any DB cluster tags to a DB snapshot when you create a snapshot.</p> <p>For more information, see Tagging Amazon RDS resources (p. 392).</p>	CLI option: <code>-copy-tags-to-snapshot</code> <code>-no-copy-tags-to-snapshot</code> RDS API parameter: <code>CopyTagsToSnapshot</code>	<p>The change occurs immediately. This setting ignores the apply immediately setting.</p>	Downtime doesn't occur during this change.
Database authentication	<p>For Multi-AZ DB clusters, only Password authentication is supported.</p>	<p>None because password authentication is the default.</p>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	Downtime doesn't occur during this change.
DB cluster instance class	<p>The compute and memory capacity of each DB instance in the Multi-AZ DB cluster, for example <code>db.r6gd.xlarge</code>.</p> <p>If possible, choose a DB instance class large enough that a typical query working set can be held in memory. When working sets are held in memory, the system can avoid writing to disk, which improves performance.</p> <p>Currently, Multi-AZ DB clusters only support <code>db.m6gd</code> and <code>db.r6gd</code> DB instance classes. For more information about DB instance classes, see DB instance classes (p. 10).</p>	CLI option: <code>--db-cluster-instance-class</code> RDS API parameter: <code>DBClusterInstanceClass</code>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	Downtime occurs during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes
DB cluster parameter group	The DB cluster parameter group that you want associated with the DB cluster. For more information, see Working with parameter groups for Multi-AZ DB clusters (p. 133) .	CLI option: --db-cluster-parameter-group-name RDS API parameter: DBClusterParameterGroupName	The parameter group change occurs immediately.	An outage doesn't occur during this change. When you change the parameter group, changes to some parameters are applied to the DB instances in the Multi-AZ DB cluster immediately without a reboot. Changes to other parameters are applied only after the DB instances are rebooted.
DB engine version	The version of database engine that you want to use.	CLI option: --engine-version RDS API parameter: EngineVersion	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	An outage occurs during this change.
Deletion protection	Enable deletion protection to prevent your DB cluster from being deleted. For more information, see Deleting a DB instance (p. 421) .	CLI option: --deletion-protection --no-deletion-protection RDS API parameter: DeletionProtection	The change occurs immediately. This setting ignores the apply immediately setting.	An outage doesn't occur during this change.
Maintenance window	The 30-minute window in which pending modifications to your DB cluster are applied. If the time period doesn't matter, choose No preference . For more information, see The Amazon RDS maintenance window (p. 354) .	CLI option: --preferred-maintenance-window RDS API parameter: PreferredMaintenanceWindow	The change occurs immediately. This setting ignores the apply immediately setting.	If there are one or more pending actions that cause downtime, and the maintenance window is changed to include the current time, those pending actions are applied immediately and downtime occurs.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes
New master password	The password for your master user account.	CLI option: <code>--master-user-password</code> RDS API parameter: <code>MasterUserPassword</code>	The change is applied asynchronously, as soon as possible. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.
Provisioned IOPS	The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB cluster. This setting is available only if Provisioned IOPS (io1) is selected as the storage type. For more information, see Provisioned IOPS SSD storage (p. 66) .	CLI option: <code>--iops</code> RDS API parameter: <code>Iops</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime doesn't occur during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes
Public access	<p>Publicly accessible to give the DB cluster a public IP address, meaning that it's accessible outside its virtual private cloud (VPC). To be publicly accessible, the DB cluster also has to be in a public subnet in the VPC.</p> <p>Not publicly accessible to make the DB cluster accessible only from inside the VPC.</p> <p>For more information, see Hiding a DB instance in a VPC from the internet (p. 2109).</p> <p>To connect to a DB cluster from outside of its VPC, the DB cluster must be publicly accessible. Also, access must be granted using the inbound rules of the DB cluster's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 2141).</p> <p>If your DB cluster isn't publicly accessible, you can use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 2015).</p>	<p>CLI option:</p> <ul style="list-style-type: none"> --publicly-accessible --no-publicly-accessible <p>RDS API parameter:</p> <ul style="list-style-type: none"> PubliclyAccessible 	The change occurs immediately. This setting ignores the apply immediately setting.	An outage doesn't occur during this change.

Console setting	Setting description	CLI option and RDS API parameter	When the change occurs	Downtime notes
VPC security group	The security groups to associate with the DB cluster. For more information, see Overview of VPC security groups (p. 2085) .	CLI option: --vpc-security-group-ids RDS API parameter: VpcSecurityGroupIds	The change is applied asynchronously, as soon as possible. This setting ignores the apply immediately setting.	An outage doesn't occur during this change.

Settings that don't apply when modifying Multi-AZ DB clusters

The following settings in the AWS CLI command [modify-db-cluster](#) and the RDS API operation [ModifyDBCluster](#) don't apply to Multi-AZ DB clusters.

You also can't modify these settings for Multi-AZ DB clusters in the console.

AWS CLI setting	RDS API setting
--allow-major-version-upgrade --no-allow-major-version-upgrade	AllowMajorVersionUpgrade
--backtrack-window	BacktrackWindow
--cloudwatch-logs-export-configuration	CloudwatchLogsExportConfiguration
--copy-tags-to-snapshot --no-copy-tags-to-snapshot	CopyTagsToSnapshot
--db-instance-parameter-group-name	DBInstanceParameterGroupName
--domain	Domain
--domain-iam-role-name	DomainIAMRoleName
--enable-global-write-forwarding --no-enable-global-write-forwarding	EnableGlobalWriteForwarding
--enable-http-endpoint --no-enable-http-endpoint	EnableHttpEndpoint
--enable-iam-database-authentication --no-enable-iam-database-authentication	EnableIAMDATABASEAuthentication
--new-db-cluster-identifier	NewDBClusterIdentifier
--option-group-name	OptionGroupName
--port	Port
--scaling-configuration	ScalingConfiguration
--storage-type	StorageType

Maintaining a DB instance

Periodically, Amazon RDS performs maintenance on Amazon RDS resources. Maintenance most often involves updates to the DB instance's underlying hardware, underlying operating system (OS), or database engine version. Updates to the operating system most often occur for security issues and should be done as soon as possible.

Some maintenance items require that Amazon RDS take your DB instance offline for a short time. Maintenance items that require a resource to be offline include required operating system or database patching. Required patching is automatically scheduled only for patches that are related to security and instance reliability. Such patching occurs infrequently (typically once every few months) and seldom requires more than a fraction of your maintenance window.

Deferred DB instance modifications that you have chosen not to apply immediately are also applied during the maintenance window. For example, you might choose to change the DB instance class or parameter group during the maintenance window. Such modifications that you specify using the **pending reboot** setting don't show up in the **Pending maintenance** list. For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

Viewing pending maintenance

View whether a maintenance update is available for your DB instance by using the RDS console, the AWS CLI, or the RDS API. If an update is available, it is indicated in the **Maintenance** column for the DB instance on the Amazon RDS console, as shown following.

The screenshot shows a table in the RDS console with the following columns: Current activity, Maintenance, VPC, and Multi-AZ. There are three rows of data:

Current activity	Maintenance	VPC	Multi-AZ
0 Connections	none	vpc-2aed394c	No
0 Connections	next window	vpc-2aed394c	No
0.02 Sessions	none	vpc-2aed394c	No

If no maintenance update is available for a DB instance, the column value is **none** for it.

If a maintenance update is available for a DB instance, the following column values are possible:

- **required** – The maintenance action will be applied to the resource and can't be deferred indefinitely.
- **available** – The maintenance action is available, but it will not be applied to the resource automatically. You can apply it manually.
- **next window** – The maintenance action will be applied to the resource during the next maintenance window.
- **In progress** – The maintenance action is in the process of being applied to the resource.

If an update is available, you can take one of the actions:

- If the maintenance value is **next window**, defer the maintenance items by choosing **Defer upgrade** from **Actions**. You can't defer a maintenance action if it has already started.
- Apply the maintenance items immediately.
- Schedule the maintenance items to start during your next maintenance window.
- Take no action.

To take an action, choose the DB instance to show its details, then choose **Maintenance & backups**. The pending maintenance items appear.

The screenshot shows the 'Maintenance & backups' tab selected in the navigation bar. Under the 'Maintenance' section, it displays the status of 'Auto minor version upgrade' as 'Enabled'. The 'Pending maintenance' section shows one item: 'Automatic minor version upgrade to postgres 9.6.11', which is a 'db-upgrade' type and is set to 'next window'. There are buttons to 'Apply now' or 'Apply at next maintenance window'. A table below lists the pending maintenance item with columns for Description, Type, Status, and Apply date.

Description	Type	Status	Apply date
Automatic minor version upgrade to postgres 9.6.11	db-upgrade	next window	February 25th 2019, 3:28:00 am UTC-8 (local)

The maintenance window determines when pending operations start, but doesn't limit the total run time of these operations. Maintenance operations aren't guaranteed to finish before the maintenance window ends, and can continue beyond the specified end time. For more information, see [The Amazon RDS maintenance window \(p. 354\)](#).

You can also view whether a maintenance update is available for your DB instance by running the [describe-pending-maintenance-actions](#) AWS CLI command.

Applying updates for a DB instance

With Amazon RDS, you can choose when to apply maintenance operations. You can decide when Amazon RDS applies updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API.

Console

To manage an update for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that has a required update.
4. For **Actions**, choose one of the following:
 - **Upgrade now**
 - **Upgrade at next window**

Note

If you choose **Upgrade at next window** and later want to delay the update, you can choose **Defer upgrade**. You can't defer a maintenance action if it has already started. To cancel a maintenance action, modify the DB instance and disable **Auto minor version upgrade**.

AWS CLI

To apply a pending update to a DB instance, use the [apply-pending-maintenance-action](#) AWS CLI command.

Example

For Linux, macOS, or Unix:

```
aws rds apply-pending-maintenance-action \
--resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db \
--apply-action system-update \
--opt-in-type immediate
```

For Windows:

```
aws rds apply-pending-maintenance-action ^
--resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db ^
--apply-action system-update ^
--opt-in-type immediate
```

Note

To defer a maintenance action, specify `undo-opt-in` for `--opt-in-type`. You can't specify `undo-opt-in` for `--opt-in-type` if the maintenance action has already started. To cancel a maintenance action, run the [modify-db-instance](#) AWS CLI command and specify `--no-auto-minor-version-upgrade`.

To return a list of resources that have at least one pending update, use the [describe-pending-maintenance-actions](#) AWS CLI command.

Example

For Linux, macOS, or Unix:

```
aws rds describe-pending-maintenance-actions \
--resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db
```

For Windows:

```
aws rds describe-pending-maintenance-actions ^
--resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db
```

You can also return a list of resources for a DB instance by specifying the `--filters` parameter of the `describe-pending-maintenance-actions` AWS CLI command. The format for the `--filters` command is `Name=filter-name,Value=resource-id,...`.

The following are the accepted values for the `Name` parameter of a filter:

- `db-instance-id` – Accepts a list of DB instance identifiers or Amazon Resource Names (ARNs). The returned list only includes pending maintenance actions for the DB instances identified by these identifiers or ARNs.
- `db-cluster-id` – Accepts a list of DB cluster identifiers or ARNs for Amazon Aurora. The returned list only includes pending maintenance actions for the DB clusters identified by these identifiers or ARNs.

For example, the following example returns the pending maintenance actions for the `sample-instance1` and `sample-instance2` DB instances.

Example

For Linux, macOS, or Unix:

```
aws rds describe-pending-maintenance-actions \
--filters Name=db-instance-id,Values=sample-instance1,sample-instance2
```

For Windows:

```
aws rds describe-pending-maintenance-actions ^
--filters Name=db-instance-id,Values=sample-instance1,sample-instance2
```

RDS API

To apply an update to a DB instance, call the Amazon RDS API [ApplyPendingMaintenanceAction](#) operation.

To return a list of resources that have at least one pending update, call the Amazon RDS API [DescribePendingMaintenanceActions](#) operation.

Maintenance for Multi-AZ deployments

Running a DB instance as a Multi-AZ deployment can further reduce the impact of a maintenance event. This result is because Amazon RDS applies operating system updates by following these steps:

1. Perform maintenance on the standby.

2. Promote the standby to primary.
3. Perform maintenance on the old primary, which becomes the new standby.

When you modify the database engine for your DB instance in a Multi-AZ deployment, Amazon RDS upgrades both primary and secondary DB instances at once. In this case, the database engine for the entire Multi-AZ deployment is shut down during the upgrade.

For more information on Multi-AZ deployments, see [Multi-AZ deployments for high availability \(p. 121\)](#).

The Amazon RDS maintenance window

Every DB instance has a weekly maintenance window during which any system changes are applied. Think of the maintenance window as an opportunity to control when modifications and software patching occur. If a maintenance event is scheduled for a given week, it's initiated during the 30-minute maintenance window you identify. Most maintenance events also complete during the 30-minute maintenance window, although larger maintenance events may take more than 30 minutes to complete.

The 30-minute maintenance window is selected at random from an 8-hour block of time per region. If you don't specify a maintenance window when you create the DB instance, RDS assigns a 30-minute maintenance window on a randomly selected day of the week.

RDS consumes some of the resources on your DB instance while maintenance is being applied. You might observe a minimal effect on performance. For a DB instance, on rare occasions, a Multi-AZ failover might be required for a maintenance update to complete.

Following, you can find the time blocks for each region from which default maintenance windows are assigned.

Region Name	Region	Time Block
US East (Ohio)	us-east-2	03:00–11:00 UTC
US East (N. Virginia)	us-east-1	03:00–11:00 UTC
US West (N. California)	us-west-1	06:00–14:00 UTC
US West (Oregon)	us-west-2	06:00–14:00 UTC
Africa (Cape Town)	af-south-1	03:00–11:00 UTC
Asia Pacific (Hong Kong)	ap-east-1	06:00–14:00 UTC
Asia Pacific (Hyderabad)	ap-south-2	06:30–14:30 UTC
Asia Pacific (Jakarta)	ap-southeast-3	08:00–16:00 UTC
Asia Pacific (Mumbai)	ap-south-1	06:00–14:00 UTC
Asia Pacific (Osaka)	ap-northeast-3	22:00–23:59 UTC
Asia Pacific (Seoul)	ap-northeast-2	13:00–21:00 UTC
Asia Pacific (Singapore)	ap-southeast-1	14:00–22:00 UTC
Asia Pacific (Sydney)	ap-southeast-2	12:00–20:00 UTC

Region Name	Region	Time Block
Asia Pacific (Tokyo)	ap-northeast-1	13:00–21:00 UTC
Canada (Central)	ca-central-1	03:00–11:00 UTC
China (Beijing)	cn-north-1	06:00–14:00 UTC
China (Ningxia)	cn-northwest-1	06:00–14:00 UTC
Europe (Frankfurt)	eu-central-1	21:00–05:00 UTC
Europe (Ireland)	eu-west-1	22:00–06:00 UTC
Europe (London)	eu-west-2	22:00–06:00 UTC
Europe (Paris)	eu-west-3	23:59–07:29 UTC
Europe (Milan)	eu-south-1	02:00–10:00 UTC
Europe (Spain)	eu-south-2	02:00–10:00 UTC
Europe (Stockholm)	eu-north-1	23:00–07:00 UTC
Europe (Zurich)	eu-central-2	02:00–10:00 UTC
Middle East (Bahrain)	me-south-1	06:00–14:00 UTC
Middle East (UAE)	me-central-1	05:00–13:00 UTC
South America (São Paulo)	sa-east-1	00:00–08:00 UTC
AWS GovCloud (US-East)	us-gov-east-1	17:00–01:00 UTC
AWS GovCloud (US-West)	us-gov-west-1	06:00–14:00 UTC

Adjusting the preferred DB instance maintenance window

The maintenance window should fall at the time of lowest usage and thus might need modification from time to time. Your DB instance is unavailable during this time only if the system changes, such as a change in DB instance class, are being applied and require an outage. Your DB instance is unavailable only for the minimum amount of time required to make the necessary changes.

In the following example, you adjust the preferred maintenance window for a DB instance.

For this example, we assume that a DB instance named *mydbinstance* exists and has a preferred maintenance window of "Sun:05:00-Sun:06:00" UTC.

Console

To adjust the preferred maintenance window

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Databases**, and then select the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB Instance** page appears.
4. In the **Maintenance** section, update the maintenance window.

Note

The maintenance window and the backup window for the DB instance cannot overlap. If you enter a value for the maintenance window that overlaps the backup window, an error message appears.

5. Choose **Continue**.

On the confirmation page, review your changes.

6. To apply the changes to the maintenance window immediately, select **Apply immediately**.
7. Choose **Modify DB Instance** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To adjust the preferred maintenance window, use the AWS CLI [modify-db-instance](#) command with the following parameters:

- `--db-instance-identifier`
- `--preferred-maintenance-window`

Example

The following code example sets the maintenance window to Tuesdays from 4:00-4:30AM UTC.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--preferred-maintenance-window Tue:04:00-Tue:04:30
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--preferred-maintenance-window Tue:04:00-Tue:04:30
```

RDS API

To adjust the preferred maintenance window, use the Amazon RDS API [ModifyDBInstance](#) operation with the following parameters:

- `DBInstanceIdentifier`
- `PreferredMaintenanceWindow`

Working with operating system updates

RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL DB instances occasionally require operating system updates. Amazon RDS upgrades the operating system to a newer version to improve database

performance and customers' overall security posture. Typically, the updates take about 10 minutes. Operating system updates don't change the DB engine version or DB instance class of a DB instance.

Operating system updates can be either optional or mandatory.

- An **optional update** doesn't have an apply date and can be applied at any time. While these updates are optional, we recommend that you apply them periodically to keep your RDS fleet up to date. RDS *does not* apply these updates automatically. To be notified when a new optional update becomes available, you can subscribe to [RDS-EVENT-0230 \(p. 676\)](#) in the security patching event category. For information about subscribing to RDS events, see [Subscribing to Amazon RDS event notification \(p. 655\)](#).
- A **mandatory update** is required and has an apply date. Plan to schedule your update before this date. After the specified apply date, Amazon RDS automatically upgrades the operating system for your DB instance to the latest version. The update is performed in a subsequent maintenance window for the DB instance.

Note

Staying current on all optional and mandatory updates might be required to meet various compliance obligations. We recommend that you apply all updates made available by RDS routinely during your maintenance windows.

You can use the AWS Management Console or the AWS CLI to determine whether an update is optional or mandatory.

Console

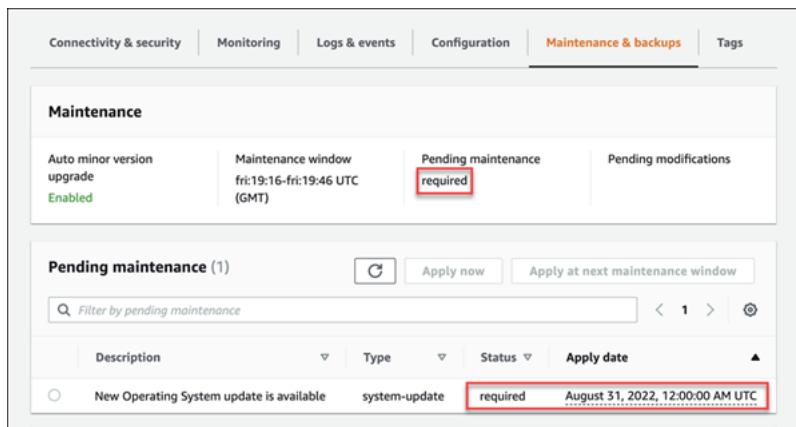

To determine whether an update is optional or mandatory using the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then select the DB instance.
3. Choose **Maintenance & backups**.
4. In the **Pending maintenance** section, find the operating system update, and check the **Status** value.

In the AWS Management Console, an optional update has its maintenance **Status** set to **available** and doesn't have an **Apply date**, as shown in the following image.

Description	Type	Status	Apply date
New Operating System update is available	system-update	available	-

A mandatory update has its maintenance **Status** set to **required** and has an **Apply date**, as shown in the following image.

AWS CLI

To determine whether an update is optional or mandatory using the AWS CLI, call the [describe-pending-maintenance-actions](#) command.

```
aws rds describe-pending-maintenance-actions
```

A mandatory operating system update includes an `AutoAppliedAfterDate` value and a `CurrentApplyDate` value. An optional operating system update doesn't include these values.

The following output shows a mandatory operating system update.

```
{
  "ResourceIdentifier": "arn:aws:rds:us-east-1:123456789012:db:mydb1",
  "PendingMaintenanceActionDetails": [
    {
      "Action": "system-update",
      "AutoAppliedAfterDate": "2022-08-31T00:00:00+00:00",
      "CurrentApplyDate": "2022-08-31T00:00:00+00:00",
      "Description": "New Operating System update is available"
    }
  ]
}
```

The following output shows an optional operating system update.

```
{
  "ResourceIdentifier": "arn:aws:rds:us-east-1:123456789012:db:mydb2",
  "PendingMaintenanceActionDetails": [
    {
      "Action": "system-update",
      "Description": "New Operating System update is available"
    }
  ]
}
```

Availability of operating system updates

Operating system updates are specific to DB engine version and DB instance class. Therefore, DB instances receive or require updates at different times. When an operating system update is available for your DB instance based on its engine version and instance class, the update appears in the console. It can also be viewed by running AWS CLI [describe-pending-maintenance-actions](#) command or by

calling the RDS [DescribePendingMaintenanceActions](#) API operation. If an update is available for your instance, you can update your operating system by following the instructions in [Applying updates for a DB instance \(p. 352\)](#).

Mandatory operating system updates schedule

We plan to use the following schedule for mandatory operating system updates. For each date in the table, the start time is 00:00 Universal Coordinated Time (UTC).

DB engine	Apply date
RDS for MySQL	August 31, 2022*
RDS for MariaDB	August 31, 2022
RDS for PostgreSQL	August 31, 2022

* For RDS for MySQL, the date applies to the Asia Pacific (Jakarta) Region only. Mandatory operating system updates are complete for other AWS Regions.

After the apply date, Amazon RDS will automatically upgrade the operating system for your DB instances to the latest version in a subsequent maintenance window. To avoid an automatic upgrade, we recommend that you schedule your update before the apply date.

Upgrading a DB instance engine version

Amazon RDS provides newer versions of each supported database engine so you can keep your DB instance up-to-date. Newer versions can include bug fixes, security enhancements, and other improvements for the database engine. When Amazon RDS supports a new version of a database engine, you can choose how and when to upgrade your database DB instances.

There are two kinds of upgrades: major version upgrades and minor version upgrades. In general, a *major engine version upgrade* can introduce changes that are not compatible with existing applications. In contrast, a *minor version upgrade* includes only changes that are backward-compatible with existing applications.

The version numbering sequence is specific to each database engine. For example, RDS for MySQL 5.7 and 8.0 are major engine versions and upgrading from any 5.7 version to any 8.0 version is a major version upgrade. RDS for MySQL version 5.7.22 and 5.7.23 are minor versions and upgrading from 5.7.22 to 5.7.23 is a minor version upgrade.

Important

You can't modify a DB instance when it is being upgraded. During an upgrade, the DB instance status is *upgrading*.

For more information about major and minor version upgrades for a specific DB engine, see the following documentation for your DB engine:

- [Upgrading the MariaDB DB engine \(p. 998\)](#)
- [Upgrading the Microsoft SQL Server DB engine \(p. 1094\)](#)
- [Upgrading the MySQL DB engine \(p. 1343\)](#)
- [Upgrading the RDS for Oracle DB engine \(p. 1757\)](#)
- [Upgrading the PostgreSQL DB engine for Amazon RDS \(p. 1839\)](#)

For major version upgrades, you must manually modify the DB engine version through the AWS Management Console, AWS CLI, or RDS API. For minor version upgrades, you can manually modify the engine version, or you can choose to enable auto minor version upgrades.

Note

Database engine upgrades require downtime. The duration of the downtime varies based on the size of your DB instance.

Topics

- [Manually upgrading the engine version \(p. 360\)](#)
- [Automatically upgrading the minor engine version \(p. 362\)](#)

Manually upgrading the engine version

To manually upgrade the engine version of a DB instance, you can use the AWS Management Console, the AWS CLI, or the RDS API.

Console

To upgrade the engine version of a DB instance by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to upgrade.

3. Choose **Modify**. The **Modify DB Instance** page appears.
4. For **DB engine version**, choose the new version.
5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see [Using the Apply Immediately setting \(p. 328\)](#).
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To upgrade the engine version of a DB instance, use the CLI `modify-db-instance` command. Specify the following parameters:

- `--db-instance-identifier` – the name of the DB instance.
- `--engine-version` – the version number of the database engine to upgrade to.

For information about valid engine versions, use the AWS CLI `describe-db-engine-versions` command.

- `--allow-major-version-upgrade` – to upgrade the major version.
- `--no-apply-immediately` – to apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --engine-version new_version \
  --allow-major-version-upgrade \
  --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --engine-version new_version ^
  --allow-major-version-upgrade ^
  --no-apply-immediately
```

RDS API

To upgrade the engine version of a DB instance, use the `ModifyDBInstance` action. Specify the following parameters:

- `DBInstanceIdentifier` – the name of the DB instance, for example *mydbinstance*.
- `EngineVersion` – the version number of the database engine to upgrade to. For information about valid engine versions, use the `DescribeDBEngineVersions` operation.
- `AllowMajorVersionUpgrade` – whether to allow a major version upgrade. To do so, set the value to `true`.
- `ApplyImmediately` – whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

Automatically upgrading the minor engine version

A *minor engine version* is an update to a DB engine version within a major engine version. For example, a major engine version might be 9.6 with the minor engine versions 9.6.11 and 9.6.12 within it.

If you want Amazon RDS to upgrade the DB engine version of a database automatically, you can enable auto minor version upgrades for the database.

When Amazon RDS designates a minor engine version as the preferred minor engine version, each database that meets both of the following conditions is upgraded to the minor engine version automatically:

- The database is running a minor version of the DB engine that is lower than the preferred minor engine version.
- The database has auto minor version upgrade enabled.

You can control whether auto minor version upgrade is enabled for a DB instance when you perform the following tasks:

- [Creating a DB instance \(p. 230\)](#)
- [Modifying a DB instance \(p. 327\)](#)
- [Creating a read replica \(p. 375\)](#)
- [Restoring a DB instance from a snapshot \(p. 452\)](#)
- [Restoring a DB instance to a specific time \(p. 499\)](#)
- [Importing a DB instance from Amazon S3 \(p. 1361\)](#) (for a MySQL backup on Amazon S3)

When you perform these tasks, you can control whether auto minor version upgrade is enabled for the DB instance in the following ways:

- Using the console, set the **Auto minor version upgrade** option.
- Using the AWS CLI, set the `--auto-minor-version-upgrade` | `--no-auto-minor-version-upgrade` option.
- Using the RDS API, set the `AutoMinorVersionUpgrade` parameter.

To determine whether a maintenance update, such as a DB engine version upgrade, is available for your DB instance, you can use the console, AWS CLI, or RDS API. You can also upgrade the DB engine version manually and adjust the maintenance window. For more information, see [Maintaining a DB instance \(p. 350\)](#).

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified minor DB engine version in a specific AWS Region. You can find the possible `--engine` values for this command in the description for the `Engine` parameter in [CreateDBInstance](#).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine engine \
--engine-version minor-version \
--region region \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade, EngineVersion:EngineVersion}" \
--output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine engine ^
--engine-version minor-version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MySQL minor version 8.0.11 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mysql \
--engine-version 8.0.11 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version 8.0.11 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.

DescribeDBEngineVersions	
AutoUpgrade	EngineVersion
False	8.0.15
False	8.0.16
False	8.0.17
False	8.0.19
False	8.0.20
False	8.0.21
True	8.0.23
False	8.0.25

In this example, the AutoUpgrade value is True for MySQL version 8.0.23. So, the automatic minor upgrade target is MySQL version 8.0.23, which is highlighted in the output.

Important

If you plan to migrate an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster soon, we strongly recommend that you turn off auto minor version upgrades for the DB instance early during planning. Migration to Aurora PostgreSQL might be delayed if the RDS for PostgreSQL version isn't yet supported by Aurora PostgreSQL. For information about Aurora PostgreSQL versions, see [Engine versions for Amazon Aurora PostgreSQL](#).

Renaming a DB instance

You can rename a DB instance by using the AWS Management Console, the AWS CLI `modify-db-instance` command, or the Amazon RDS API `ModifyDBInstance` action. Renaming a DB instance can have far-reaching effects. The following is a list of considerations before you rename a DB instance.

- When you rename a DB instance, the endpoint for the DB instance changes, because the URL includes the name you assigned to the DB instance. You should always redirect traffic from the old URL to the new one.
- When you rename a DB instance, the old DNS name that was used by the DB instance is immediately deleted, although it could remain cached for a few minutes. The new DNS name for the renamed DB instance becomes effective in about 10 minutes. The renamed DB instance is not available until the new name becomes effective.
- You cannot use an existing DB instance name when renaming an instance.
- All read replicas associated with a DB instance remain associated with that instance after it is renamed. For example, suppose you have a DB instance that serves your production database and the instance has several associated read replicas. If you rename the DB instance and then replace it in the production environment with a DB snapshot, the DB instance that you renamed will still have the read replicas associated with it.
- Metrics and events associated with the name of a DB instance are maintained if you reuse a DB instance name. For example, if you promote a read replica and rename it to be the name of the previous primary DB instance, the events and metrics associated with the primary DB instance are associated with the renamed instance.
- DB instance tags remain with the DB instance, regardless of renaming.
- DB snapshots are retained for a renamed DB instance.

Note

A DB instance is an isolated database environment running in the cloud. A DB instance can host multiple databases, or a single Oracle database with multiple schemas. For information about changing a database name, see the documentation for your DB engine.

Renaming to replace an existing DB instance

The most common reasons for renaming a DB instance are that you are promoting a read replica or you are restoring data from a DB snapshot or point-in-time recovery (PITR). By renaming the database, you can replace the DB instance without having to change any application code that references the DB instance. In these cases, you would do the following:

1. Stop all traffic going to the primary DB instance. This can involve redirecting traffic from accessing the databases on the DB instance or some other way you want to use to prevent traffic from accessing your databases on the DB instance.
2. Rename the primary DB instance to a name that indicates it is no longer the primary DB instance as described later in this topic.
3. Create a new primary DB instance by restoring from a DB snapshot or by promoting a read replica, and then give the new instance the name of the previous primary DB instance.
4. Associate any read replicas with the new primary DB instance.

If you delete the old primary DB instance, you are responsible for deleting any unwanted DB snapshots of the old primary DB instance.

For information about promoting a read replica, see [Promoting a read replica to be a standalone DB instance \(p. 377\)](#).

Important

The DB instance is rebooted when it is renamed.

Console

To rename a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to rename.
4. Choose **Modify**.
5. In **Settings**, enter a new name for **DB instance identifier**.
6. Choose **Continue**.
7. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).
8. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To rename a DB instance, use the AWS CLI command `modify-db-instance`. Provide the current `--db-instance-identifier` value and `--new-db-instance-identifier` parameter with the new name of the DB instance.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier DBInstanceIdentifier \
  --new-db-instance-identifier NewDBInstanceIdentifier
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier DBInstanceIdentifier ^
  --new-db-instance-identifier NewDBInstanceIdentifier
```

RDS API

To rename a DB instance, call Amazon RDS API operation `ModifyDBInstance` with the following parameters:

- `DBInstanceIdentifier` — existing name for the instance
- `NewDBInstanceIdentifier` — new name for the instance

Rebooting a DB instance

You might need to reboot your DB instance, usually for maintenance reasons. For example, if you make certain modifications, or if you change the DB parameter group associated with the DB instance, you must reboot the instance for the changes to take effect.

Note

If a DB instance isn't using the latest changes to its associated DB parameter group, the AWS Management Console shows the DB parameter group with a status of **pending-reboot**. The **pending-reboot** parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance. For more information about parameter groups, see [Working with parameter groups \(p. 289\)](#).

Rebooting a DB instance restarts the database engine service. Rebooting a DB instance results in a momentary outage, during which the DB instance status is set to *rebooting*.

If the Amazon RDS DB instance is configured for Multi-AZ, you can perform the reboot with a failover. An Amazon RDS event is created when the reboot is completed. If your DB instance is a Multi-AZ deployment, you can force a failover from one Availability Zone (AZ) to another when you reboot. When you force a failover of your DB instance, Amazon RDS automatically switches to a standby replica in another Availability Zone, and updates the DNS record for the DB instance to point to the standby DB instance. As a result, you need to clean up and re-establish any existing connections to your DB instance. Rebooting with failover is beneficial when you want to simulate a failure of a DB instance for testing, or restore operations to the original AZ after a failover occurs. For more information, see [Multi-AZ deployments for high availability \(p. 121\)](#).

Warning

When you force a failover of your DB instance, the database is abruptly interrupted. The DB instance and its client sessions might not have time to shut down gracefully. To avoid the possibility of data loss, we recommend stopping transactions on your DB instance before rebooting with a failover.

On RDS for Microsoft SQL Server, reboot with failover reboots only the primary DB instance. After the failover, the primary DB instance becomes the new secondary DB instance. Parameters might not be updated for Multi-AZ instances. For reboot without failover, both the primary and secondary DB instances reboot, and parameters are updated after the reboot. If the DB instance is unresponsive, we recommend reboot without failover.

Note

When you force a failover from one Availability Zone to another when you reboot, the Availability Zone change might not be reflected in the AWS Management Console, and in calls to the AWS CLI and RDS API, for several minutes.

You can't reboot your DB instance if it isn't in the available state. Your database can be unavailable for several reasons, such as an in-progress backup, a previously requested modification, or a maintenance-window action.

The time required to reboot your DB instance depends on the crash recovery process, database activity at the time of reboot, and the behavior of your specific DB engine. To improve the reboot time, we recommend that you reduce database activity as much as possible during the reboot process. Reducing database activity reduces rollback activity for in-transit transactions.

For a DB instance with read replicas, you can reboot the source DB instance and its read replicas independently. After a reboot completes, replication resumes automatically.

Console

To reboot a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to reboot.
3. For **Actions**, choose **Reboot**.

The **Reboot DB Instance** page appears.

4. (Optional) Choose **Reboot with failover?** to force a failover from one AZ to another.
5. Choose **Reboot** to reboot your DB instance.

Alternatively, choose **Cancel**.

AWS CLI

To reboot a DB instance by using the AWS CLI, call the `reboot-db-instance` command.

Example Simple reboot

For Linux, macOS, or Unix:

```
aws rds reboot-db-instance \
--db-instance-identifier mydbinstance
```

For Windows:

```
aws rds reboot-db-instance ^
--db-instance-identifier mydbinstance
```

Example Reboot with failover

To force a failover from one AZ to the other, use the `--force-failover` parameter.

For Linux, macOS, or Unix:

```
aws rds reboot-db-instance \
--db-instance-identifier mydbinstance \
--force-failover
```

For Windows:

```
aws rds reboot-db-instance ^
--db-instance-identifier mydbinstance ^
--force-failover
```

RDS API

To reboot a DB instance by using the Amazon RDS API, call the `RebootDBInstance` operation.

Rebooting Multi-AZ DB clusters and reader DB instances

You might need to reboot your Multi-AZ DB cluster, usually for maintenance reasons. For example, if you make certain modifications or change the DB cluster parameter group associated with a DB cluster, you reboot the DB cluster. Doing so causes the changes to take effect.

If a DB cluster isn't using the latest changes to its associated DB cluster parameter group, the AWS Management Console shows the DB cluster parameter group with a status of **pending-reboot**. The **pending-reboot** parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB cluster, manually reboot the DB cluster. For more information about parameter groups, see [Working with parameter groups for Multi-AZ DB clusters \(p. 133\)](#).

Rebooting a DB cluster restarts the database engine service. Rebooting a DB cluster results in a momentary outage, during which the DB cluster status is set to **rebooting**.

You can't reboot your DB cluster if it isn't in the **Available** state. Your database can be unavailable for several reasons, such as an in-progress backup, a previously requested modification, or a maintenance-window action.

Important

When you reboot the writer instance of a Multi-AZ DB cluster, it doesn't affect the reader DB instances in that DB cluster and no failover occurs. When you reboot a reader DB instance, no failover occurs. To fail over a Multi-AZ DB cluster, choose **Failover** in the console, call the AWS CLI command [failover-db-cluster](#), or call the API operation [FailoverDBCluster](#).

The time required to reboot your DB cluster depends on the crash recovery process, the database activity at the time of reboot, and the behavior of your specific DB cluster. To improve the reboot time, we recommend that you reduce database activity as much as possible during the reboot process. Reducing database activity reduces rollback activity for in-transit transactions.

Multi-AZ DB clusters don't support reboot with a failover.

Console

To reboot a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the Multi-AZ DB cluster that you want to reboot.
3. For **Actions**, choose **Reboot**.

The **Reboot DB cluster** page appears.

4. Choose **Reboot** to reboot your DB cluster.

Or choose **Cancel**.

AWS CLI

To reboot a Multi-AZ DB cluster by using the AWS CLI, call the `reboot-db-cluster` command.

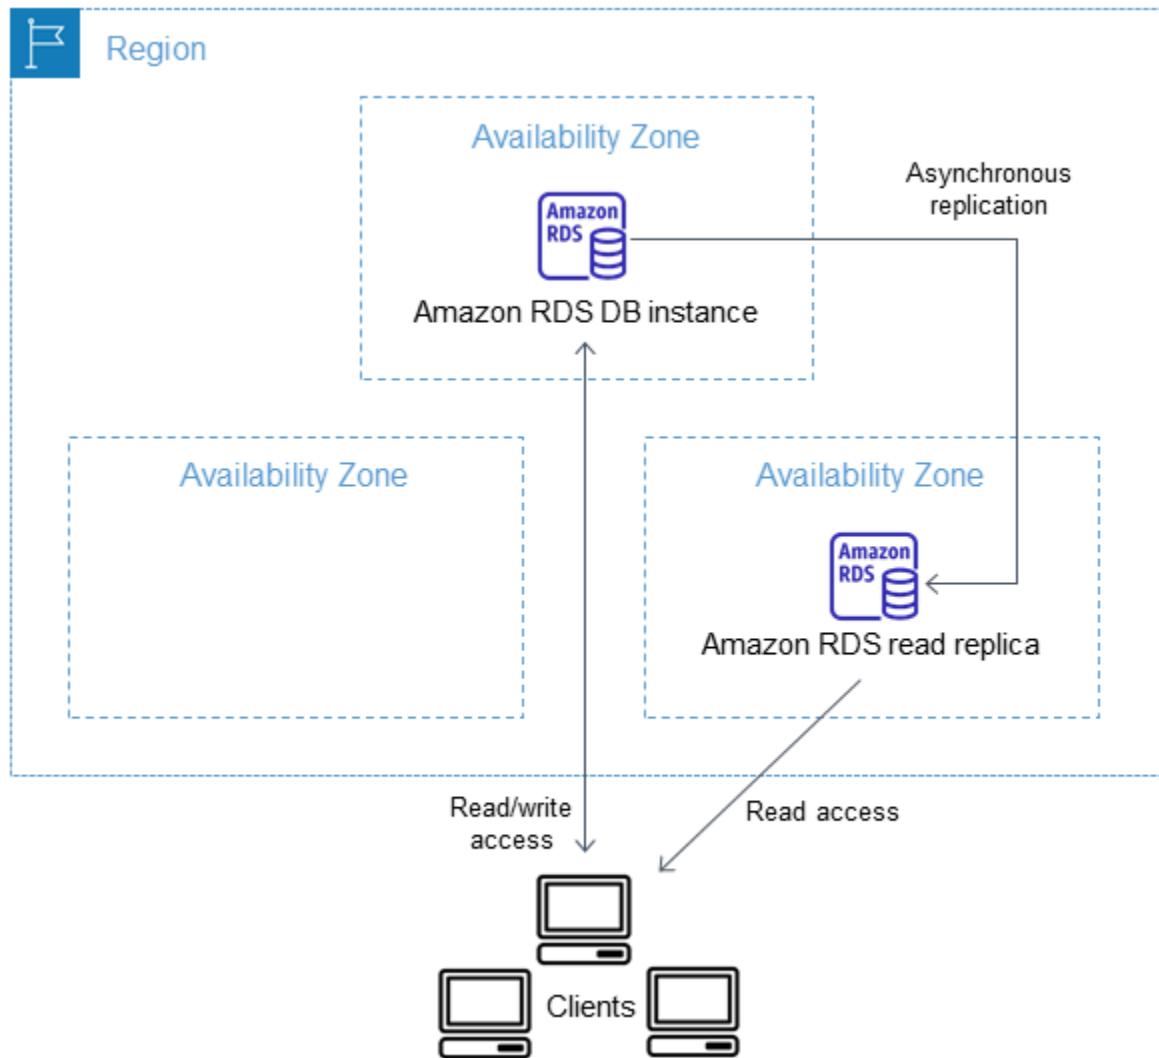

```
aws rds reboot-db-cluster --db-cluster-identifier mymultiazdbcluster
```

RDS API

To reboot a Multi-AZ DB cluster by using the Amazon RDS API, call the [RebootDBCluster](#) operation.

Working with read replicas

Amazon RDS uses the MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL DB engines' built-in replication functionality to create a special type of DB instance called a read replica from a source DB instance. The source DB instance becomes the primary DB instance. Updates made to the primary DB instance are asynchronously copied to the read replica. You can reduce the load on your primary DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads.

Note

The information following applies to creating Amazon RDS read replicas either in the same AWS Region as the source DB instance, or in a separate AWS Region. The information following doesn't apply to setting up replication with an instance that is running on an Amazon EC2 instance or that is on-premises.

When you create a read replica, you first specify an existing DB instance as the source. Then Amazon RDS takes a snapshot of the source instance and creates a read-only instance from the snapshot. Amazon RDS then uses the asynchronous replication method for the DB engine to update the read replica whenever there is a change to the primary DB instance. The read replica operates as a DB instance that allows only

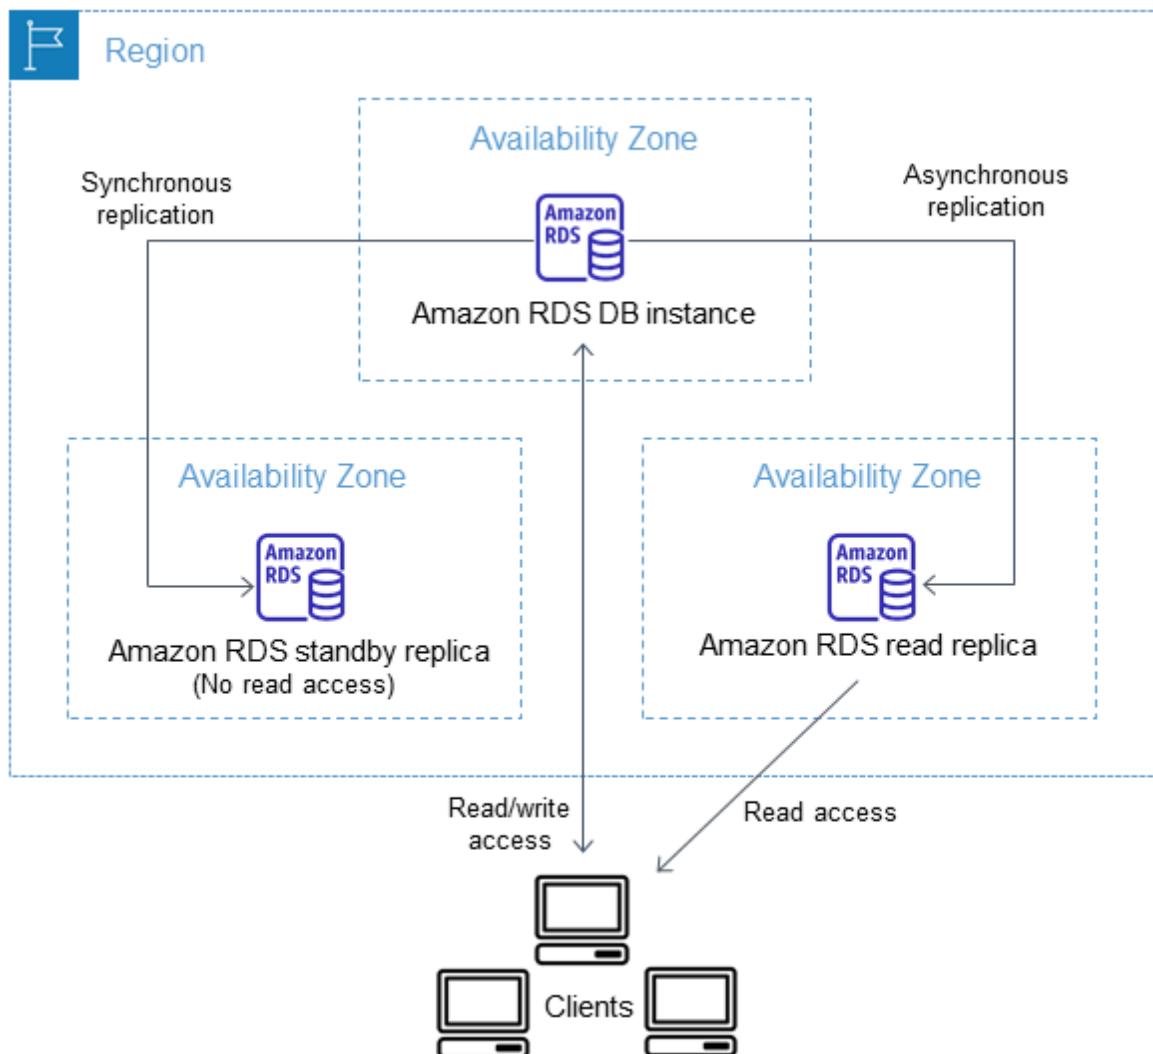

read-only connections. Applications connect to a read replica the same way they do to any DB instance. Amazon RDS replicates all databases from the source DB instance.

Note

The Oracle DB engine supports replica databases in mounted mode. A mounted replica doesn't accept user connections and so can't serve a read-only workload. The primary use for mounted replicas is cross-Region disaster recovery. For more information, see [Working with read replicas for Amazon RDS for Oracle \(p. 1630\)](#).

In some cases, a read replica resides in a different AWS Region from its primary DB instance. In these cases, Amazon RDS sets up a secure communications channel between the primary DB instance and the read replica. Amazon RDS establishes any AWS security configurations needed to enable the secure channel, such as adding security group entries. For more information about cross-Region read replicas, see [Creating a read replica in a different AWS Region \(p. 383\)](#).

You can configure a read replica for a DB instance that also has a standby replica configured for high availability in a Multi-AZ deployment. Replication with the standby replica is synchronous, and the standby replica can't serve read traffic.

For more information about high availability and standby replicas, see [Multi-AZ deployments for high availability \(p. 121\)](#).

Read replicas are supported by the MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL DB engines. In this section, you can find general information about using read replicas with all of these engines.

Topics

- [Working with read replicas for Amazon RDS for Oracle \(p. 1630\)](#)
- [Working with read replicas for Amazon RDS for PostgreSQL \(p. 1852\)](#)

Overview of Amazon RDS read replicas

Deploying one or more read replicas for a given source DB instance might make sense in a variety of scenarios, including the following:

- Scaling beyond the compute or I/O capacity of a single DB instance for read-heavy database workloads. You can direct this excess read traffic to one or more read replicas.
- Serving read traffic while the source DB instance is unavailable. In some cases, your source DB instance might not be able to take I/O requests, for example due to I/O suspension for backups or scheduled maintenance. In these cases, you can direct read traffic to your read replicas. For this use case, keep in mind that the data on the read replica might be "stale" because the source DB instance is unavailable.
- Business reporting or data warehousing scenarios where you might want business reporting queries to run against a read replica, rather than your production DB instance.
- Implementing disaster recovery. You can promote a read replica to a standalone instance as a disaster recovery solution if the primary DB instance fails.

By default, a read replica is created with the same storage type as the source DB instance. However, you can create a read replica that has a different storage type from the source DB instance based on the options listed in the following table.

Source DB instance storage type	Source DB instance storage allocation	Read replica storage type options
Provisioned IOPS	100 GiB–64 TiB	Provisioned IOPS, General Purpose, Magnetic
General Purpose	100 GiB–64 TiB	Provisioned IOPS, General Purpose, Magnetic
General Purpose	<100 GiB	General Purpose, Magnetic
Magnetic	100 GiB–6 TiB	Provisioned IOPS, General Purpose, Magnetic

Source DB instance storage type	Source DB instance storage allocation	Read replica storage type options
Magnetic	<100 GiB	General Purpose, Magnetic

Note

When you increase the allocated storage of a read replica, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error.

Amazon RDS doesn't support circular replication. You can't configure a DB instance to serve as a replication source for an existing DB instance. You can only create a new read replica from an existing DB instance. For example, if **MyDBInstance** replicates to **ReadReplica1**, you can't configure **ReadReplica1** to replicate back to **MyDBInstance**. For MariaDB and MySQL, and for certain versions of PostgreSQL, you can create a read replica from an existing read replica. For example, from **ReadReplica1**, you can create a new read replica, such as **ReadReplica2**. For Oracle and SQL Server, you can't create a read replica from an existing read replica.

If you no longer need read replicas, you can explicitly delete them using the same mechanisms for deleting a DB instance. If you delete a source DB instance without deleting its read replicas in the same AWS Region, each read replica is promoted to a standalone DB instance. For information about deleting a DB instance, see [Deleting a DB instance \(p. 421\)](#). For information about read replica promotion, see [Promoting a read replica to be a standalone DB instance \(p. 377\)](#).

If you have cross-Region read replicas, see [Cross-Region replication considerations \(p. 387\)](#) for information related to deleting the source DB instance for a cross-Region read replica.

Differences between read replicas for different DB engines

Because Amazon RDS DB engines implement replication differently, there are several significant differences you should know about, as shown in the following table.

Feature or behavior	MySQL and MariaDB	Oracle	PostgreSQL	SQL Server
What is the replication method?	Logical replication.	Physical replication.	Physical replication.	Physical replication.
How are transaction logs purged?	RDS for MySQL and RDS for MariaDB keep any binary logs that haven't been applied.	If a primary DB instance has no cross-Region read replicas, Amazon RDS for Oracle keeps a minimum of two hours of transaction logs on the source DB instance. Logs are purged from the source DB instance after two hours or after the archive log retention hours setting has passed, whichever is longer. Logs are purged from the read replica	PostgreSQL has the parameter <code>wal_keep_segments</code> that dictates how many write ahead log (WAL) files are kept to provide data to the read replicas. The parameter value specifies the number of logs to keep.	The Virtual Log File (VLF) of the transaction log file on the primary replica can be truncated after it is no longer required for the secondary replicas. The VLF can only be marked as inactive

Feature or behavior	MySQL and MariaDB	Oracle	PostgreSQL	SQL Server
		<p>after the archive log retention hours setting has passed only if they have been successfully applied to the database.</p> <p>In some cases, a primary DB instance might have one or more cross-Region read replicas. If so, Amazon RDS for Oracle keeps the transaction logs on the source DB instance until they have been transmitted and applied to all cross-Region read replicas.</p> <p>For information about setting archive log retention hours, see Retaining archived redo logs (p. 1564).</p>		when the log records have been hardened in the replicas. Regardless of how fast the disk subsystems are in the primary replica, the transaction log will keep the VLFs until the slowest replica has hardened it.
Can a replica be made writable?	Yes. You can enable the MySQL or MariaDB read replica to be writable.	No. An Oracle read replica is a physical copy, and Oracle doesn't allow for writes in a read replica. You can promote the read replica to make it writable. The promoted read replica has the replicated data to the point when the request was made to promote it.	No. A PostgreSQL read replica is a physical copy, and PostgreSQL doesn't allow for a read replica to be made writable.	No. A SQL Server read replica is a physical copy and also doesn't allow for writes. You can promote the read replica to make it writable. The promoted read replica has the replicated data up to the point when the request was made to promote it.

Feature or behavior	MySQL and MariaDB	Oracle	PostgreSQL	SQL Server
Can backups be performed on the replica?	Yes. Automatic backups and manual snapshots are supported on RDS for MySQL or RDS for MariaDB read replicas.	Yes. Automatic backups and manual snapshots are supported on RDS for Oracle read replicas.	Yes, you can create a manual snapshot of RDS for PostgreSQL read replicas, but automatic backups aren't supported.	No. Automatic backups and manual snapshots aren't supported on RDS for SQL Server read replicas.
Can you use parallel replication?	Yes. All supported MariaDB and MySQL versions allow for parallel replication threads.	Yes. Redo log data is always transmitted in parallel from the primary database to all of its read replicas.	No. PostgreSQL has a single process handling replication.	Yes. Redo log data is always transmitted in parallel from the primary database to all of its read replicas.
Can you maintain a replica in a mounted rather than a read-only state?	No.	Yes. The primary use for mounted replicas is cross-Region disaster recovery. An Active Data Guard license isn't required for mounted replicas. For more information, see Working with read replicas for Amazon RDS for Oracle (p. 1630) .	No.	No.

Creating a read replica

You can create a read replica from an existing DB instance using the AWS Management Console, AWS CLI, or RDS API. You create a read replica by specifying `SourceDBInstanceIdentifier`, which is the DB instance identifier of the source DB instance that you want to replicate from.

When you create a read replica, Amazon RDS takes a DB snapshot of your source DB instance and begins replication. As a result, you experience a brief I/O suspension on your source DB instance while the DB snapshot occurs.

Note

The I/O suspension typically lasts about one minute. You can avoid the I/O suspension if the source DB instance is a Multi-AZ deployment, because in that case the snapshot is taken from the secondary DB instance.

An active, long-running transaction can slow the process of creating the read replica. We recommend that you wait for long-running transactions to complete before creating a read replica. If you create multiple read replicas in parallel from the same source DB instance, Amazon RDS takes only one snapshot at the start of the first create action.

When creating a read replica, there are a few things to consider. First, you must enable automatic backups on the source DB instance by setting the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica. To enable automatic backups on an RDS for MySQL read replica, first create the read replica, then modify the read replica to enable automatic backups.

Note

Within an AWS Region, we strongly recommend that you create all read replicas in the same virtual private cloud (VPC) based on Amazon VPC as the source DB instance. If you create a read replica in a different VPC from the source DB instance, classless inter-domain routing (CIDR) ranges can overlap between the replica and the RDS system. CIDR overlap makes the replica unstable, which can negatively impact applications connecting to it. If you receive an error when creating the read replica, choose a different destination DB subnet group. For more information, see [Working with a DB instance in a VPC \(p. 2103\)](#).

You can't create a read replica in a different AWS account from the source DB instance.

Console

To create a read replica from a source DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to use as the source for a read replica.
4. For **Actions**, choose **Create read replica**.
5. For **DB instance identifier**, enter a name for the read replica.
6. Choose your instance specifications. We recommend that you use the same DB instance class and storage type as the source DB instance for the read replica.
7. For **Multi-AZ deployment**, choose **Yes** to create a standby of your replica in another Availability Zone for failover support for the replica.

Note

Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

8. To create an encrypted read replica:
 - a. Choose **Enable encryption**.
 - b. For **AWS KMS key**, choose the AWS KMS key identifier of the KMS key.

Note

The source DB instance must be encrypted. To learn more about encrypting the source DB instance, see [Encrypting Amazon RDS resources \(p. 2000\)](#).

9. Specify other settings, such as storage autoscaling.

For information about each setting, see [Settings for DB instances \(p. 237\)](#).

10. Choose **Create read replica**.

After the read replica is created, you can see it on the **Databases** page in the RDS console. It shows **Replica** in the **Role** column.

AWS CLI

To create a read replica from a source DB instance, use the AWS CLI command `create-db-instance-read-replica`. This example also enables storage autoscaling.

You can specify other settings. For information about each setting, see [Settings for DB instances \(p. 237\)](#).

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
--db-instance-identifier myreadreplica \
--source-db-instance-identifier mydbinstance \
--max-allocated-storage 1000
```

For Windows:

```
aws rds create-db-instance-read-replica ^
--db-instance-identifier myreadreplica ^
--source-db-instance-identifier mydbinstance ^
--max-allocated-storage 1000
```

RDS API

To create a read replica from a source MySQL, MariaDB, Oracle, PostgreSQL, or SQL Server DB instance, call the Amazon RDS API [CreateDBInstanceReadReplica](#) operation with the following required parameters:

- `DBInstanceIdentifier`
- `SourceDBInstanceIdentifier`

Promoting a read replica to be a standalone DB instance

You can promote a read replica into a standalone DB instance. When you promote a read replica, the DB instance is rebooted before it becomes available.

There are several reasons you might want to promote a read replica to a standalone DB instance:

- **Performing DDL operations (MySQL and MariaDB only)** – DDL operations, such as creating or rebuilding indexes, can take time and impose a significant performance penalty on your DB instance. You can perform these operations on a MySQL or MariaDB read replica once the read replica is in sync with its primary DB instance. Then you can promote the read replica and direct your applications to use the promoted instance.
- **Sharding** – Sharding embodies the "share-nothing" architecture and essentially involves breaking a large database into several smaller databases. One common way to split a database is splitting tables that are not joined in the same query onto different hosts. Another method is duplicating a table across multiple hosts and then using a hashing algorithm to determine which host receives a given update. You can create read replicas corresponding to each of your shards (smaller databases) and

promote them when you decide to convert them into standalone shards. You can then carve out the key space (if you are splitting rows) or distribution of tables for each of the shards depending on your requirements.

- **Implementing failure recovery** – You can use read replica promotion as a data recovery scheme if the primary DB instance fails. This approach complements synchronous replication, automatic failure detection, and failover.

If you are aware of the ramifications and limitations of asynchronous replication and you still want to use read replica promotion for data recovery, you can. To do this, first create a read replica and then monitor the primary DB instance for failures. In the event of a failure, do the following:

1. Promote the read replica.
2. Direct database traffic to the promoted DB instance.
3. Create a replacement read replica with the promoted DB instance as its source.

When you promote a read replica, the new DB instance that is created retains the option group and the parameter group of the former read replica. The promotion process can take several minutes or longer to complete, depending on the size of the read replica. After you promote the read replica to a new DB instance, it's just like any other DB instance. For example, you can create read replicas from the new DB instance and perform point-in-time restore operations. Because the promoted DB instance is no longer a read replica, you can't use it as a replication target. If a source DB instance has several read replicas, promoting one of the read replicas to a DB instance has no effect on the other replicas.

Backup duration is a function of the number of changes to the database since the previous backup. If you plan to promote a read replica to a standalone instance, we recommend that you enable backups and complete at least one backup prior to promotion. In addition, you can't promote a read replica to a standalone instance when it has the backing-up status. If you have enabled backups on your read replica, configure the automated backup window so that daily backups don't interfere with read replica promotion.

The following steps show the general process for promoting a read replica to a DB instance:

1. Stop any transactions from being written to the primary DB instance, and then wait for all updates to be made to the read replica. Database updates occur on the read replica after they have occurred on the primary DB instance, and this replication lag can vary significantly. Use the [Replica Lag](#) metric to determine when all updates have been made to the read replica.
2. For MySQL and MariaDB only: If you need to make changes to the MySQL or MariaDB read replica, you must set the `read_only` parameter to `0` in the DB parameter group for the read replica. You can then perform all needed DDL operations, such as creating indexes, on the read replica. Actions taken on the read replica don't affect the performance of the primary DB instance.
3. Promote the read replica by using the **Promote** option on the Amazon RDS console, the AWS CLI command [promote-read-replica](#), or the [PromoteReadReplica](#) Amazon RDS API operation.

Note

The promotion process takes a few minutes to complete. When you promote a read replica, replication is stopped and the read replica is rebooted. When the reboot is complete, the read replica is available as a new DB instance.

4. (Optional) Modify the new DB instance to be a Multi-AZ deployment. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#) and [Multi-AZ deployments for high availability \(p. 121\)](#).

Console

To promote a read replica to a standalone DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the Amazon RDS console, choose **Databases**.
The **Databases** pane appears. Each read replica shows **Replica** in the **Role** column.
3. Choose the read replica that you want to promote.
4. For **Actions**, choose **Promote**.
5. On the **Promote Read Replica** page, enter the backup retention period and the backup window for the newly promoted DB instance.
6. When the settings are as you want them, choose **Continue**.
7. On the acknowledgment page, choose **Promote Read Replica**.

AWS CLI

To promote a read replica to a standalone DB instance, use the AWS CLI `promote-read-replica` command.

Example

For Linux, macOS, or Unix:

```
aws rds promote-read-replica \
--db-instance-identifier myreadreplica
```

For Windows:

```
aws rds promote-read-replica ^
--db-instance-identifier myreadreplica
```

RDS API

To promote a read replica to a standalone DB instance, call the Amazon RDS API `PromoteReadReplica` operation with the required parameter `DBInstanceIdentifier`.

Monitoring read replication

You can monitor the status of a read replica in several ways. The Amazon RDS console shows the status of a read replica in the **Replication** section of the **Connectivity & security** tab in the read replica details. To view the details for a read replica, choose the name of the read replica in the list of DB instances in the Amazon RDS console.

Replication (2)			
<input type="text"/> Filter by replication			
DB instance	Role	Region & AZ	Replication source
mydbinstancecf	Primary	us-east-1d	-
mydbinstancecfreplica	Replica	us-east-1f	mydbinstancecf

You can also see the status of a read replica using the AWS CLI `describe-db-instances` command or the Amazon RDS API `DescribeDBInstances` operation.

The status of a read replica can be one of the following:

- **replicating** – The read replica is replicating successfully.
- **replication degraded (SQL Server only)** – Replicas are receiving data from the primary instance, but one or more databases might be not getting updates. This can occur, for example, when a replica is in the process of setting up newly created databases.

The status doesn't transition from `replication degraded` to `error`, unless an error occurs during the degraded state.

- **error** – An error has occurred with the replication. Check the **Replication Error** field in the Amazon RDS console or the event log to determine the exact error. For more information about troubleshooting a replication error, see [Troubleshooting a MySQL read replica problem \(p. 1399\)](#).
- **terminated (MariaDB, MySQL, or PostgreSQL only)** – Replication is terminated. This occurs if replication is stopped for more than 30 consecutive days, either manually or due to a replication error. In this case, Amazon RDS terminates replication between the primary DB instance and all read replicas. Amazon RDS does this to prevent increased storage requirements on the source DB instance and long failover times.

Broken replication can affect storage because the logs can grow in size and number due to the high volume of errors messages being written to the log. Broken replication can also affect failure recovery due to the time Amazon RDS requires to maintain and process the large number of logs during recovery.

- **terminated (Oracle only)** – Replication is terminated. This occurs if replication is stopped for more than 8 hours because there isn't enough storage remaining on the read replica. In this case, Amazon RDS terminates replication between the primary DB instance and the affected read replica. This status is a terminal state, and the read replica must be re-created.
- **stopped (MariaDB or MySQL only)** – Replication has stopped because of a customer-initiated request.
- **replication stop point set (MySQL only)** – A customer-initiated stop point was set using the [`mysql.rds_start_replication_until` \(p. 1452\)](#) stored procedure and the replication is in progress.
- **replication stop point reached (MySQL only)** – A customer-initiated stop point was set using the [`mysql.rds_start_replication_until` \(p. 1452\)](#) stored procedure and replication is stopped because the stop point was reached.

You can see where a DB instance is being replicated and if so, check its replication status. On the **Databases** page in the RDS console, it shows **Primary** in the **Role** column. Choose its DB instance name. On its detail page, on the **Connectivity & security** tab, its replication status is under **Replication**.

Monitoring replication lag

You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric.

For MariaDB and MySQL, the ReplicaLag metric reports the value of the Seconds_Behind_Master field of the SHOW REPLICA STATUS command. Common causes for replication lag for MySQL and MariaDB are the following:

- A network outage.
- Writing to tables with indexes on a read replica. If the `read_only` parameter is not set to 0 on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL and the XtraDB storage engine on MariaDB.

Note

Previous versions of MariaDB and MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MariaDB version before 10.5 or a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

When the ReplicaLag metric reaches 0, the replica has caught up to the primary DB instance. If the ReplicaLag metric returns -1, then replication is currently not active. ReplicaLag = -1 is equivalent to Seconds_Behind_Master = NULL.

For Oracle, the ReplicaLag metric is the sum of the Apply Lag value and the difference between the current time and the apply lag's DATUM_TIME value. The DATUM_TIME value is the last time the read replica received data from its source DB instance. For more information, see [V\\$DATAGUARD_STATS](#) in the Oracle documentation.

For SQL Server, the ReplicaLag metric is the maximum lag of databases that have fallen behind, in seconds. For example, if you have two databases that lag 5 seconds and 10 seconds, respectively, then ReplicaLag is 10 seconds. The ReplicaLag metric returns the value of the following query.

```
SELECT MAX(secondary_lag_seconds) max_lag FROM sys.dm_hadr_database_replica_states;
```

For more information, see [secondary_lag_seconds](#) in the Microsoft documentation.

ReplicaLag returns -1 if RDS can't determine the lag, such as during replica setup, or when the read replica is in the `error` state.

Note

New databases aren't included in the lag calculation until they are accessible on the read replica.

For PostgreSQL, the ReplicaLag metric returns the value of the following query.

```
SELECT extract(epoch from now() - pg_last_xact_replay_timestamp()) AS reader_lag
```

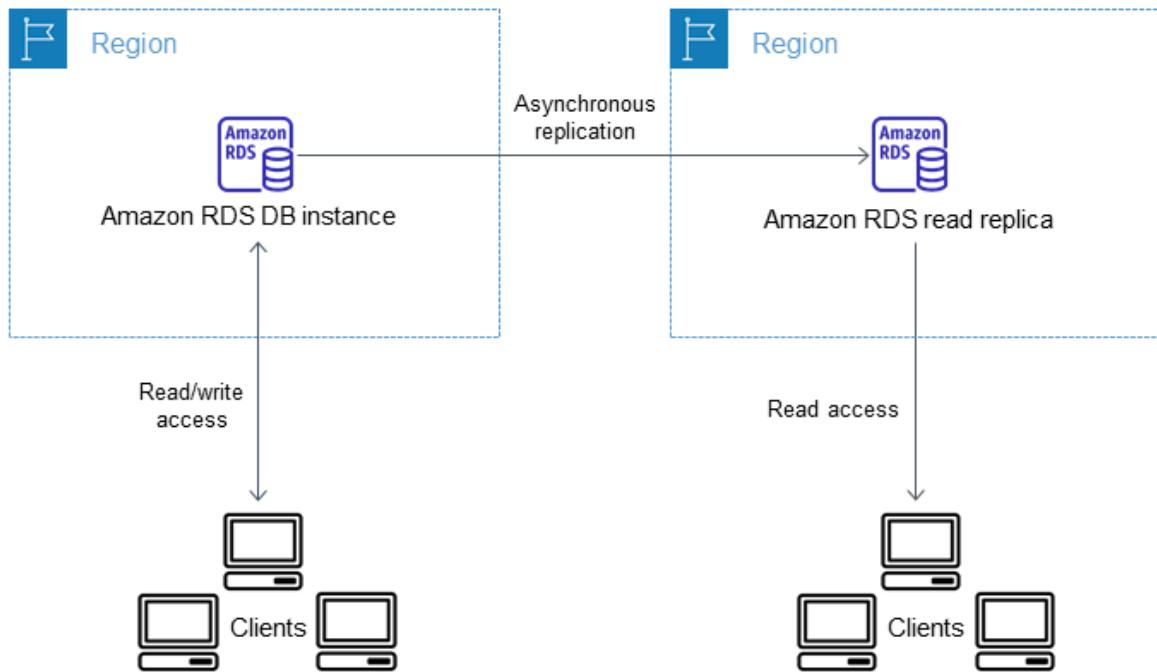

PostgreSQL versions 9.5.2 and later use physical replication slots to manage write ahead log (WAL) retention on the source instance. For each cross-Region read replica instance, Amazon RDS creates a physical replication slot and associates it with the instance. Two Amazon CloudWatch metrics, Oldest

Replication Slot Lag and Transaction Logs Disk Usage, show how far behind the most lagging replica is in terms of WAL data received and how much storage is being used for WAL data. The Transaction Logs Disk Usage value can substantially increase when a cross-Region read replica is lagging significantly.

For more information about monitoring a DB instance with CloudWatch, see [Monitoring Amazon RDS metrics with Amazon CloudWatch \(p. 528\)](#).

Creating a read replica in a different AWS Region

With Amazon RDS, you can create a read replica in a different AWS Region from the source DB instance.

You create a read replica in a different AWS Region to do the following:

- Improve your disaster recovery capabilities.
- Scale read operations into an AWS Region closer to your users.
- Make it easier to migrate from a data center in one AWS Region to a data center in another AWS Region.

Creating a read replica in a different AWS Region from the source instance is similar to creating a replica in the same AWS Region. You can use the AWS Management Console, run the [create-db-instance-read-replica](#) command, or call the [CreateDBInstanceReadReplica](#) API operation.

Note

To create an encrypted read replica in a different AWS Region from the source DB instance, the source DB instance must be encrypted.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with cross-Region replication, see [Cross-Region read replicas \(p. 83\)](#).

Creating a cross-Region read replica

The following procedures show how to create a read replica from a source MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL DB instance in a different AWS Region.

Console

You can create a read replica across AWS Regions using the AWS Management Console.

To create a read replica across AWS Regions with the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL DB instance that you want to use as the source for a read replica.
4. For **Actions**, choose **Create read replica**.
5. For **DB instance identifier**, enter a name for the read replica.
6. Choose the **Destination Region**.
7. Choose the instance specifications you want to use. We recommend that you use the same DB instance class and storage type for the read replica.
8. To create an encrypted read replica in another AWS Region:
 - a. Choose **Enable encryption**.
 - b. For **AWS KMS key**, choose the AWS KMS key identifier of the KMS key in the destination AWS Region.

Note

To create an encrypted read replica, the source DB instance must be encrypted. To learn more about encrypting the source DB instance, see [Encrypting Amazon RDS resources \(p. 2000\)](#).

9. Choose other options, such as storage autoscaling.
10. Choose **Create read replica**.

AWS CLI

To create a read replica from a source MySQL, Microsoft SQL Server, MariaDB, Oracle, or PostgreSQL DB instance in a different AWS Region, you can use the `create-db-instance-read-replica` command. In this case, you use `create-db-instance-read-replica` from the AWS Region where you want the read replica (destination Region) and specify the Amazon Resource Name (ARN) for the source DB instance. An ARN uniquely identifies a resource created in Amazon Web Services.

For example, if your source DB instance is in the US East (N. Virginia) Region, the ARN looks similar to this example:

```
arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

For information about ARNs, see [Working with Amazon Resource Names \(ARNs\) in Amazon RDS \(p. 402\)](#).

To create a read replica in a different AWS Region from the source DB instance, you can use the AWS CLI `create-db-instance-read-replica` command from the destination AWS Region. The following parameters are required for creating a read replica in another AWS Region:

- **--region** – The destination AWS Region where the read replica is created.
- **--source-db-instance-identifier** – The DB instance identifier for the source DB instance. This identifier must be in the ARN format for the source AWS Region.
- **--db-instance-identifier** – The identifier for the read replica in the destination AWS Region.

Example of a cross-Region read replica

The following code creates a read replica in the US West (Oregon) Region from a source DB instance in the US East (N. Virginia) Region.

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --region us-west-2 \
    --source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

For Windows:

```
aws rds create-db-instance-read-replica ^
    --db-instance-identifier myreadreplica ^
    --region us-west-2 ^
    --source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

The following parameter is also required for creating an encrypted read replica in another AWS Region:

- **--kms-key-id** – The AWS KMS key identifier of the KMS key to use to encrypt the read replica in the destination AWS Region.

Example of an encrypted cross-Region read replica

The following code creates an encrypted read replica in the US West (Oregon) Region from a source DB instance in the US East (N. Virginia) Region.

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --region us-west-2 \
    --source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance \
    --kms-key-id my-us-west-2-key
```

For Windows:

```
aws rds create-db-instance-read-replica ^
    --db-instance-identifier myreadreplica ^
    --region us-west-2 ^
    --source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance ^
    --kms-key-id my-us-west-2-key
```

The **--source-region** option is required when you're creating an encrypted read replica between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. For **--source-region**, specify the AWS Region of the source DB instance.

If `--source-region` isn't specified, specify a `--pre-signed-url` value. A *presigned URL* is a URL that contains a Signature Version 4 signed request for the `create-db-instance-read-replica` command that's called in the source AWS Region. To learn more about the `pre-signed-url` option, see [create-db-instance-read-replica](#) in the *AWS CLI Command Reference*.

RDS API

To create a read replica from a source MySQL, Microsoft SQL Server, MariaDB, Oracle, or PostgreSQL DB instance in a different AWS Region, you can call the Amazon RDS API operation [CreateDBInstanceReadReplica](#). In this case, you call [CreateDBInstanceReadReplica](#) from the AWS Region where you want the read replica (destination Region) and specify the Amazon Resource Name (ARN) for the source DB instance. An ARN uniquely identifies a resource created in Amazon Web Services.

To create an encrypted read replica in a different AWS Region from the source DB instance, you can use the Amazon RDS API [CreateDBInstanceReadReplica](#) operation from the destination AWS Region. To create an encrypted read replica in another AWS Region, you must specify a value for `PreSignedURL`. `PreSignedURL` should contain a request for the [CreateDBInstanceReadReplica](#) operation to call in the source AWS Region where the read replica is created in. To learn more about `PreSignedUrl`, see [CreateDBInstanceReadReplica](#).

For example, if your source DB instance is in the US East (N. Virginia) Region, the ARN looks similar to the following.

```
arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

For information about ARNs, see [Working with Amazon Resource Names \(ARNs\) in Amazon RDS \(p. 402\)](#).

```

How Amazon RDS does cross-Region replication

Amazon RDS uses the following process to create a cross-Region read replica. Depending on the AWS Regions involved and the amount of data in the databases, this process can take hours to complete. You can use this information to determine how far the process has proceeded when you create a cross-Region read replica:

1. Amazon RDS begins configuring the source DB instance as a replication source and sets the status to *modifying*.
2. Amazon RDS begins setting up the specified read replica in the destination AWS Region and sets the status to *creating*.
3. Amazon RDS creates an automated DB snapshot of the source DB instance in the source AWS Region. The format of the DB snapshot name is `rds:<InstanceID>-<timestamp>`, where `<InstanceID>` is the identifier of the source instance, and `<timestamp>` is the date and time the copy started. For example, `rds:mysourceinstance-2013-11-14-09-24` was created from the instance `mysourceinstance` at `2013-11-14-09-24`. During the creation of an automated DB snapshot, the source DB instance status remains *modifying*, the read replica status remains *creating*, and the DB snapshot status is *creating*. The progress column of the DB snapshot page in the console reports how far the DB snapshot creation has progressed. When the DB snapshot is complete, the status of both the DB snapshot and source DB instance are set to *available*.
4. Amazon RDS begins a cross-Region snapshot copy for the initial data transfer. The snapshot copy is listed as an automated snapshot in the destination AWS Region with a status of *creating*. It has the same name as the source DB snapshot. The progress column of the DB snapshot display indicates how far the copy has progressed. When the copy is complete, the status of the DB snapshot copy is set to *available*.
5. Amazon RDS then uses the copied DB snapshot for the initial data load on the read replica. During this phase, the read replica is in the list of DB instances in the destination, with a status of *creating*. When the load is complete, the read replica status is set to *available*, and the DB snapshot copy is deleted.
6. When the read replica reaches the available status, Amazon RDS starts by replicating the changes made to the source instance since the start of the create read replica operation. During this phase, the replication lag time for the read replica is greater than 0.

For information about replication lag time, see [Monitoring read replication \(p. 380\)](#).

Cross-Region replication considerations

All of the considerations for performing replication within an AWS Region apply to cross-Region replication. The following extra considerations apply when replicating between AWS Regions:

- A source DB instance can have cross-Region read replicas in multiple AWS Regions.
- You can replicate between the GovCloud (US-East) and GovCloud (US-West) Regions, but not into or out of GovCloud (US).
- For Microsoft SQL Server, Oracle, and PostgreSQL DB instances, you can only create a cross-Region Amazon RDS read replica from a source Amazon RDS DB instance that is not a read replica of another Amazon RDS DB instance. This limitation doesn't apply to MariaDB and MySQL DB instances.
- You can expect to see a higher level of lag time for any read replica that is in a different AWS Region than the source instance. This lag time comes from the longer network channels between regional data centers.
- For cross-Region read replicas, any of the create read replica commands that specify the `--db-subnet-group-name` parameter must specify a DB subnet group from the same VPC.
- Due to the limit on the number of access control list (ACL) entries for a VPC, we can't guarantee more than five cross-Region read replica instances.

- In most cases, the read replica uses the default DB parameter group and DB option group for the specified DB engine.

For the MySQL and Oracle DB engines, you can specify a custom parameter group for the read replica in the `--db-parameter-group-name` option of the AWS CLI command [create-db-instance-read-replica](#). You can't specify a custom parameter group when you use the AWS Management Console.

- The read replica uses the default security group.
- For MariaDB, Microsoft SQL Server, MySQL, and Oracle DB instances, when the source DB instance for a cross-Region read replica is deleted, the read replica is promoted.
- For PostgreSQL DB instances, when the source DB instance for a cross-Region read replica is deleted, the replication status of the read replica is set to terminated. The read replica isn't promoted.

You have to promote the read replica manually or delete it.

Requesting a cross-Region read replica

To communicate with the source Region to request the creation of a cross-Region read replica, the requester (IAM role or IAM user) must have access to the source DB instance and the source Region.

Certain conditions in the requester's IAM policy can cause the request to fail. The following examples assume that the source DB instance is in US East (Ohio) and the read replica is created in US East (N. Virginia). These examples show conditions in the requester's IAM policy that cause the request to fail:

- The requester's policy has a condition for `aws:RequestedRegion`.

```
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:RequestedRegion": "us-east-1"
    }
}
```

The request fails because the policy doesn't allow access to the source Region. For a successful request, specify both the source and destination Regions.

```
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:RequestedRegion": [
            "us-east-1",
            "us-east-2"
        ]
    }
}
```

- The requester's policy doesn't allow access to the source DB instance.

```
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "arn:aws:rds:us-east-1:123456789012:db:myreadreplica"
```

...

For a successful request, specify both the source instance and the replica.

```
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": [
    "arn:aws:rds:us-east-1:123456789012:db:myreadreplica",
    "arn:aws:rds:us-east-2:123456789012:db:mydbinstance"
]
...
```

- The requester's policy denies aws:ViaAWSservice.

```
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
    "Bool": {"aws:ViaAWSservice": "false"}
}
```

Communication with the source Region is made by RDS on the requester's behalf. For a successful request, don't deny calls made by AWS services.

- The requester's policy has a condition for aws:SourceVpc or aws:SourceVpce.

These requests might fail because when RDS makes the call to the remote Region, it isn't from the specified VPC or VPC endpoint.

If you need to use one of the previous conditions that would cause a request to fail, you can include a second statement with aws:CalledVia in your policy to make the request succeed. For example, you can use aws:CalledVia with aws:SourceVpce as shown here:

```
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
    "Condition" : {
        "ForAnyValue:StringEquals" : {
            "aws:SourceVpce": "vpce-1a2b3c4d"
        }
    }
},
{
    "Effect": "Allow",
    "Action": [
        "rds:CreateDBInstanceReadReplica"
    ],
    "Resource": "*",
    "Condition": {
        "ForAnyValue:StringEquals": {
            "aws:CalledVia": [
                "rds.amazonaws.com"
            ]
        }
    }
}
```

For more information, see [Policies and permissions in IAM](#) in the *IAM User Guide*.

Authorizing the read replica

After a cross-Region DB read replica creation request returns success, RDS starts the replica creation in the background. An authorization for RDS to access the source DB instance is created. This authorization links the source DB instance to the read replica, and allows RDS to copy only to the specified read replica.

The authorization is verified by RDS using the `rds:CrossRegionCommunication` permission in the service-linked IAM role. If the replica is authorized, RDS communicates with the source Region and completes the replica creation.

RDS doesn't have access to DB instances that weren't authorized previously by a `CreateDBInstanceReadReplica` request. The authorization is revoked when read replica creation completes.

RDS uses the service-linked role to verify the authorization in the source Region. If you delete the service-linked role during the replication creation process, the creation fails.

For more information, see [Using service-linked roles](#) in the *IAM User Guide*.

Using AWS Security Token Service credentials

Session tokens from the global AWS Security Token Service (AWS STS) endpoint are valid only in AWS Regions that are enabled by default (commercial Regions). If you use credentials from the `assumeRole` API operation in AWS STS, use the regional endpoint if the source Region is an opt-in Region. Otherwise, the request fails. This happens because your credentials must be valid in both Regions, which is true for opt-in Regions only when the regional AWS STS endpoint is used.

To use the global endpoint, make sure that it's enabled for both Regions in the operations. Set the global endpoint to `Valid in all AWS Regions` in the AWS STS account settings.

The same rule applies to credentials in the `presigned URL` parameter.

For more information, see [Managing AWS STS in an AWS Region](#) in the *IAM User Guide*.

Cross-Region replication costs

The data transferred for cross-Region replication incurs Amazon RDS data transfer charges. These cross-Region replication actions generate charges for the data transferred out of the source AWS Region:

- When you create a read replica, Amazon RDS takes a snapshot of the source instance and transfers the snapshot to the read replica AWS Region.
- For each data modification made in the source databases, Amazon RDS transfers data from the source AWS Region to the read replica AWS Region.

For more information about data transfer pricing, see [Amazon RDS pricing](#).

For MySQL and MariaDB instances, you can reduce your data transfer costs by reducing the number of cross-Region read replicas that you create. For example, suppose that you have a source DB instance in one AWS Region and want to have three read replicas in another AWS Region. In this case, you create only one of the read replicas from the source DB instance. You create the other two replicas from the first read replica instead of the source DB instance.

For example, if you have `source-instance-1` in one AWS Region, you can do the following:

- Create `read-replica-1` in the new AWS Region, specifying `source-instance-1` as the source.
- Create `read-replica-2` from `read-replica-1`.

- Create `read-replica-3` from `read-replica-1`.

In this example, you are only charged for the data transferred from `source-instance-1` to `read-replica-1`. You aren't charged for the data transferred from `read-replica-1` to the other two replicas because they are all in the same AWS Region. If you create all three replicas directly from `source-instance-1`, you are charged for the data transfers to all three replicas.

Tagging Amazon RDS resources

You can use Amazon RDS tags to add metadata to your Amazon RDS resources. You can use the tags to add your own notations about database instances, snapshots, Aurora clusters, and so on. Doing so can help you to document your Amazon RDS resources. You can also use the tags with automated maintenance procedures.

In particular, you can use these tags with IAM policies. You can use them to manage access to RDS resources and to control what actions can be applied to the RDS resources. You can also use these tags to track costs by grouping expenses for similarly tagged resources.

You can tag the following Amazon RDS resources:

- DB instances
- DB clusters
- Read replicas
- DB snapshots
- DB cluster snapshots
- Reserved DB instances
- Event subscriptions
- DB option groups
- DB parameter groups
- DB cluster parameter groups
- DB subnet groups
- RDS Proxies
- RDS Proxy endpoints

Note

Currently, you can't tag RDS Proxies and RDS Proxy endpoints by using the AWS Management Console.

Overview of Amazon RDS resource tags

An Amazon RDS tag is a name-value pair that you define and associate with an Amazon RDS resource. The name is referred to as the key. Supplying a value for the key is optional. You can use tags to assign arbitrary information to an Amazon RDS resource. You can use a tag key, for example, to define a category, and the tag value might be an item in that category. For example, you might define a tag

key of "project" and a tag value of "Salix". In this case, these indicate that the Amazon RDS resource is assigned to the Salix project. You can also use tags to designate Amazon RDS resources as being used for test or production by using a key such as environment=test or environment=production. We recommend that you use a consistent set of tag keys to make it easier to track metadata associated with Amazon RDS resources.

In addition, you can use conditions in your IAM policies to control access to AWS resources based on the tags on that resource. You can do this by using the global `aws:ResourceTag/tag-key` condition key. For more information, see [Controlling access to AWS resources](#) in the *AWS Identity and Access Management User Guide*.

Each Amazon RDS resource has a tag set, which contains all the tags that are assigned to that Amazon RDS resource. A tag set can contain as many as 50 tags, or it can be empty. If you add a tag to an RDS resource with the same key as an existing resource tag, the new value overwrites the old.

AWS doesn't apply any semantic meaning to your tags; tags are interpreted strictly as character strings. RDS can set tags on a DB instance or other RDS resources. Tag setting depends on the options that you use when you create the resource. For example, Amazon RDS might add a tag indicating that a DB instance is for production or for testing.

- The tag key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with aws:. The string can contain only the set of Unicode letters, digits, white space, '_', ':', '.', '/', '=', '+', '-', '@' (Java regex: "^(\\p{L}\\p{Z}\\p{N}_.:/=+\\-@]*\$").
 - The tag value is an optional string value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with aws:. The string can contain only the set of Unicode letters, digits, white space, '_', ':', '.', '/', '=', '+', '-', '@' (Java regex: "^(\\p{L}\\p{Z}\\p{N}_.:/=+\\-@]*\$").

Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of `project=Trinity` and `cost-center=Trinity`.

You can use the AWS Management Console, the AWS CLI, or the Amazon RDS API to add, list, and delete tags on Amazon RDS resources. When using the CLI or API, make sure to provide the Amazon Resource Name (ARN) for the RDS resource to work with. For more information about constructing an ARN, see [Constructing an ARN for Amazon RDS \(p. 402\)](#).

Tags are cached for authorization purposes. Because of this, additions and updates to tags on Amazon RDS resources can take several minutes before they are available.

Using tags for access control with IAM

You can use tags with IAM policies to manage access to Amazon RDS resources. You can also use tags to control what actions can be applied to the Amazon RDS resources.

For information on managing access to tagged resources with IAM policies, see [Identity and access management for Amazon RDS \(p. 2016\)](#).

Using tags to produce detailed billing reports

You can also use tags to track costs by grouping expenses for similarly tagged resources.

Use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. Then, to see the cost of combined resources, organize your

billing information according to resources with the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see [Using Cost Allocation Tags](#) in the [AWS Billing User Guide](#).

Note

You can add a tag to a snapshot, however, your bill will not reflect this grouping.

Adding, listing, and removing tags

The following procedures show how to perform typical tagging operations on resources related to DB instances.

Console

The process to tag an Amazon RDS resource is similar for all resources. The following procedure shows how to tag an Amazon RDS DB instance.

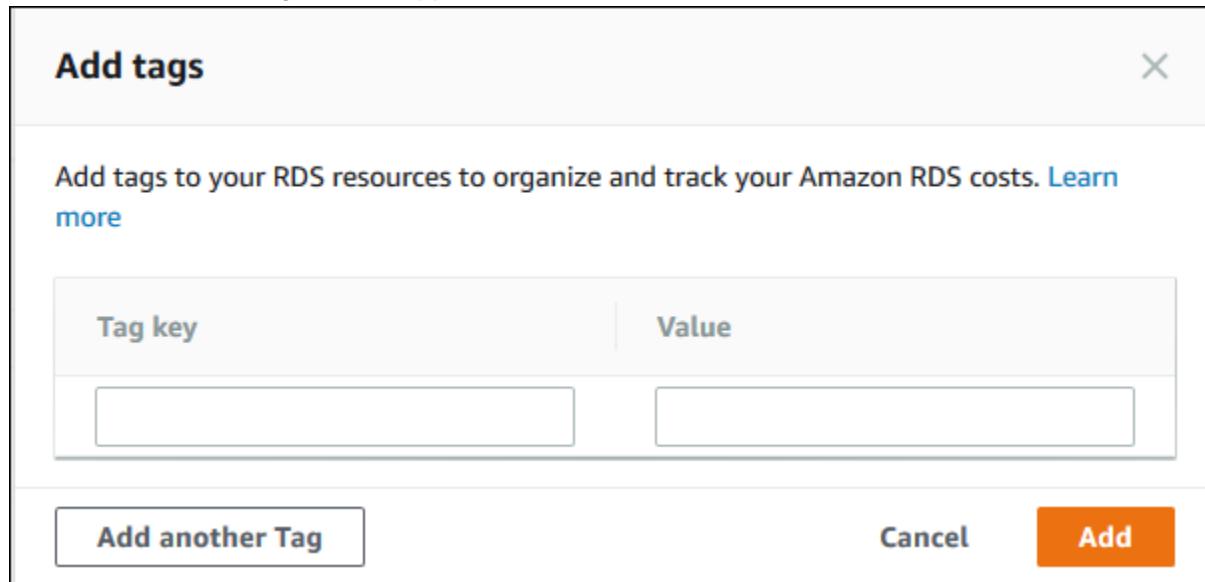

To add a tag to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

Note

To filter the list of DB instances in the **Databases** pane, enter a text string for **Filter databases**. Only DB instances that contain the string appear.

3. Choose the name of the DB instance that you want to tag to show its details.
4. In the details section, scroll down to the **Tags** section.
5. Choose **Add**. The **Add tags** window appears.

6. Enter a value for **Tag key** and **Value**.
7. To add another tag, you can choose **Add another Tag** and enter a value for its **Tag key** and **Value**.
Repeat this step as many times as necessary.
8. Choose **Add**.

To delete a tag from a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

Note

To filter the list of DB instances in the **Databases** pane, enter a text string in the **Filter databases** box. Only DB instances that contain the string appear.

3. Choose the name of the DB instance to show its details.
4. In the details section, scroll down to the **Tags** section.
5. Choose the tag you want to delete.

Tags (1)		Edit	Delete	Add
<input type="text"/> Filter tag key		< 1 >	<input type="checkbox"/>	<input type="radio"/>
Tag key	Value			
<input checked="" type="checkbox"/> workload-type	other			

6. Choose **Delete**, and then choose **Delete** in the **Delete tags** window.

AWS CLI

You can add, list, or remove tags for a DB instance using the AWS CLI.

- To add one or more tags to an Amazon RDS resource, use the AWS CLI command [add-tags-to-resource](#).
- To list the tags on an Amazon RDS resource, use the AWS CLI command [list-tags-for-resource](#).
- To remove one or more tags from an Amazon RDS resource, use the AWS CLI command [remove-tags-from-resource](#).

To learn more about how to construct the required ARN, see [Constructing an ARN for Amazon RDS \(p. 402\)](#).

RDS API

You can add, list, or remove tags for a DB instance using the Amazon RDS API.

- To add a tag to an Amazon RDS resource, use the [AddTagsToResource](#) operation.
- To list tags that are assigned to an Amazon RDS resource, use the [ListTagsForResource](#).
- To remove tags from an Amazon RDS resource, use the [RemoveTagsFromResource](#) operation.

To learn more about how to construct the required ARN, see [Constructing an ARN for Amazon RDS \(p. 402\)](#).

When working with XML using the Amazon RDS API, tags use the following schema:

```
<Tagging>
  <TagSet>
```

```

<Tag>
  <Key>Project</Key>
  <Value>Trinity</Value>
</Tag>
<Tag>
  <Key>User</Key>
  <Value>Jones</Value>
</Tag>
</TagSet>
</Tagging>

```

The following table provides a list of the allowed XML tags and their characteristics. Values for Key and Value are case-dependent. For example, project=Trinity and PROJECT=Trinity are two distinct tags.

Tagging element	Description
TagSet	A tag set is a container for all tags assigned to an Amazon RDS resource. There can be only one tag set per resource. You work with a TagSet only through the Amazon RDS API.
Tag	A tag is a user-defined key-value pair. There can be from 1 to 50 tags in a tag set.
Key	A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with aws: or rds:. The string can only contain only the set of Unicode letters, digits, white space, '_', '.', '/', '=', '+', '-' (Java regex: " <code>^([\u00p{L}\u00p{Z}\u00p{N}_:=+\u00p{-}]*\$</code> "). Keys must be unique to a tag set. For example, you cannot have a key-pair in a tag set with the key the same but with different values, such as project/Trinity and project/Xanadu.
Value	A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with aws: or rds:. The string can only contain only the set of Unicode letters, digits, white space, '_', '.', '/', '=', '+', '-' (Java regex: " <code>^([\u00p{L}\u00p{Z}\u00p{N}_:=+\u00p{-}]*\$</code> "). Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of project/Trinity and cost-center/Trinity.

Using the AWS Tag Editor

You can browse and edit the tags on your RDS resources in the AWS Management Console by using the AWS Tag editor. For more information, see [Tag Editor](#) in the *AWS Resource Groups User Guide*.

Copying tags to DB instance snapshots

When you create or restore a DB instance, you can specify that the tags from the DB instance are copied to snapshots of the DB instance. Copying tags ensures that the metadata for the DB snapshots matches that of the source DB instance. It also ensures that any access policies for the DB snapshots also match those of the source DB instance.

You can specify that tags are copied to DB snapshots for the following actions:

- Creating a DB instance.

- Restoring a DB instance.
- Creating a read replica.
- Copying a DB snapshot.

In most cases, tags aren't copied by default. However, when you restore a DB instance from a DB snapshot, RDS checks whether you specify new tags. If yes, the new tags are added to the restored DB instance. If there are no new tags, RDS looks for the tags from the source DB instance for the DB snapshot. RDS then adds those tags to the restored DB instance.

To prevent tags from source DB instances from being added to restored DB instances, we recommend that you specify new tags when restoring a DB instance.

Note

In some cases, you might include a value for the `--tag-key` parameter of the `create-db-snapshot` AWS CLI command. Or you might supply at least one tag to the `CreateDBSnapshot` API operation. In these cases, RDS doesn't copy tags from the source DB instance to the new DB snapshot. This functionality applies even if the source DB instance has the `--copy-tags-to-snapshot` (`CopyTagsToSnapshot`) option turned on.

If you take this approach, you can create a copy of a DB instance from a DB snapshot. This approach avoids adding tags that don't apply to the new DB instance. You create your DB snapshot using the AWS CLI `create-db-snapshot` command (or the `CreateDBSnapshot` RDS API operation). After you create your DB snapshot, you can add tags as described later in this topic.

Tutorial: Use tags to specify which DB instances to stop

Suppose that you're creating a number of DB instances in a development or test environment. You need to keep all of these DB instances for several days. Some of the DB instances run tests overnight. Other DB instances can be stopped overnight and started again the next day. The following example shows how to assign a tag to those DB instances that are suitable to stop overnight. Then the example shows how a script can detect which DB instances have that tag and then stop those DB instances. In this example, the value portion of the key-value pair doesn't matter. The presence of the `stopable` tag signifies that the DB instance has this user-defined property.

To specify which DB instances to stop

1. Determine the ARN of a DB instance that you want to designate as stoppable.

The commands and APIs for tagging work with ARNs. That way, they can work seamlessly across AWS Regions, AWS accounts, and different types of resources that might have identical short names. You can specify the ARN instead of the DB instance ID in CLI commands that operate on DB instances. Substitute the name of your own DB instances for `dev-test-db-instance`. In subsequent commands that use ARN parameters, substitute the ARN of your own DB instance. The ARN includes your own AWS account ID and the name of the AWS Region where your DB instance is located.

```
$ aws rds describe-db-instances --db-instance-identifier dev-test-db-instance \
  --query "*[].{DBInstance:DBInstanceArn}" --output text
arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
```

2. Add the tag `stopable` to this DB instance.

You choose the name for this tag. This approach means that you can avoid devising a naming convention that encodes all relevant information in names. In such a convention, you might encode information in the DB instance name or names of other resources. Because this example treats

the tag as an attribute that is either present or absent, it omits the Value= part of the --tags parameter.

```
$ aws rds add-tags-to-resource \
--resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance \
--tags Key=stoppable
```

3. Confirm that the tag is present in the DB instance.

These commands retrieve the tag information for the DB instance in JSON format and in plain tab-separated text.

```
$ aws rds list-tags-for-resource \
--resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
{
    "TagList": [
        {
            "Key": "stoppable",
            "Value": ""
        }
    ]
}
aws rds list-tags-for-resource \
--resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance --output
text
TAGLIST stoppable
```

4. To stop all the DB instances that are designated as stoppable, prepare a list of all your DB instances. Loop through the list and check if each DB instance is tagged with the relevant attribute.

This Linux example uses shell scripting. This scripting saves the list of DB instance ARNs to a temporary file and then performs CLI commands for each DB instance.

```
$ aws rds describe-db-instances --query "[].[DBInstanceArn]" --output text >/tmp/
db_instance_arns.lst
$ for arn in $(cat /tmp/db_instance_arns.lst)
do
    match=$(aws rds list-tags-for-resource --resource-name $arn --output text | grep
stoppable)"
    if [[ ! -z "$match" ]]
    then
        echo "DB instance $arn is tagged as stoppable. Stopping it now."
    # Note that you need to get the DB instance identifier from the ARN.
        dbid=$(echo $arn | sed -e 's/.*/\1')
        aws rds stop-db-instance --db-instance-identifier $dbid
    fi
done

DB instance arn:arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance is tagged as
stoppable. Stopping it now.
{
    "DBInstance": {
        "DBInstanceIdentifier": "dev-test-db-instance",
        "DBInstanceClass": "db.t3.medium",
        ...
    }
}
```

You can run a script like this at the end of each day to make sure that nonessential DB instances are stopped. You might also schedule a job using a utility such as cron to perform such a check each night. For example, you might do this in case some DB instances were left running by mistake. Here, you might fine-tune the command that prepares the list of DB instances to check.

The following command produces a list of your DB instances, but only the ones in available state. The script can ignore DB instances that are already stopped, because they will have different status values such as stopped or stopping.

```
$ aws rds describe-db-instances \
--query '[].{DBInstanceArn:DBInstanceArn,DBInstanceStatus:DBInstanceState}|?DBInstanceState == `available`|[]|.{DBInstanceArn:DBInstanceArn}' \
--output text
arn:aws:rds:us-east-1:123456789102:db:db-instance-2447
arn:aws:rds:us-east-1:123456789102:db:db-instance-3395
arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
arn:aws:rds:us-east-1:123456789102:db:pg2-db-instance
```

Tip

You can use assigning tags and finding DB instances with those tags to reduce costs in other ways. For example, take this scenario with DB instances used for development and testing. In this case, you might designate some DB instances to be deleted at the end of each day. Or you might designate them to have their DB instances changed to small DB instance classes during times of expected low usage.

Using tags to enable backups in AWS Backup

AWS Backup is a fully managed backup service that makes it easy to centralize and automate the backup of data across AWS services in the cloud and on premises. You can manage backups of your Amazon RDS DB instances in AWS Backup.

To enable backups in AWS Backup, you use resource tagging to associate your DB instance with a backup plan.

This example assumes that you have already created a backup plan in AWS Backup. You use exactly the same tag for your DB instance that is in your backup plan, as shown in the following figure.

Backup plan tags (1)		Edit	Delete	Add
<input type="text"/> Filter by tags				« 1 » @
<input type="checkbox"/>	Tag key		Value	
<input type="checkbox"/>	BackupPlan		Test	

For more information about AWS Backup, see the [AWS Backup Developer Guide](#).

You can assign a tag to a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. The following examples are for the console and CLI.

Console

To assign a tag to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the link for the DB instance to which you want to assign a tag.
4. On the database details page, choose the **Tags** tab.
5. Under **Tags**, choose **Add tags**.
6. Under **Add tags**:

- a. For **Tag key**, enter **BackupPlan**.
- b. For **Value**, enter **Test**.
- c. Choose **Add**.

The result is shown under **Tags**.

Tags (1)	
<input type="checkbox"/>	Tags
<input type="checkbox"/>	BackupPlan
	Value
	Test

CLI

To assign a tag to a DB instance

- Use the following CLI command:

For Linux, macOS, or Unix:

```
aws rds add-tags-to-resource \
--resource-name arn:aws:rds:us-east-1:123456789012:db:new-orcl-db \
--tags Key=BackupPlan,Value=Test
```

For Windows:

```
aws rds add-tags-to-resource ^
--resource-name arn:aws:rds:us-east-1:123456789012:db:new-orcl-db ^
--tags Key=BackupPlan,Value=Test
```

The `add-tags-to-resource` CLI command returns no output.

To confirm that the DB instance is tagged

- Use the following CLI command:

For Linux, macOS, or Unix:

```
aws rds list-tags-for-resource \
--resource-name arn:aws:rds:us-east-1:123456789012:db:new-orcl-db
```

For Windows:

```
aws rds list-tags-for-resource ^
--resource-name arn:aws:rds:us-east-1:123456789012:db:new-orcl-db
```

The `list-tags-for-resource` CLI command returns the following output:

```
{
  "TagList": [
    {
      "Key": "BackupPlan",
      "Value": "Test"
    }
  ]
}
```

Working with Amazon Resource Names (ARNs) in Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). For certain Amazon RDS operations, you must uniquely identify an Amazon RDS resource by specifying its ARN. For example, when you create an RDS DB instance read replica, you must supply the ARN for the source DB instance.

Constructing an ARN for Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). You can construct an ARN for an Amazon RDS resource using the following syntax.

`arn:aws:rds:<region>:<account number>:<resourcetype>:<name>`

Region Name	Region	Endpoint	Protocol	
US East (Ohio)	us-east-2	rds.us-east-2.amazonaws.com	HTTPS	
		rds-fips.us-east-2.api.aws	HTTPS	
		rds.us-east-2.api.aws	HTTPS	
		rds-fips.us-east-2.amazonaws.com	HTTPS	
US East (N. Virginia)	us-east-1	rds.us-east-1.amazonaws.com	HTTPS	
		rds-fips.us-east-1.api.aws	HTTPS	
		rds-fips.us-east-1.amazonaws.com	HTTPS	
		rds.us-east-1.api.aws	HTTPS	
US West (N. California)	us-west-1	rds.us-west-1.amazonaws.com	HTTPS	
		rds.us-west-1.api.aws	HTTPS	
		rds-fips.us-west-1.amazonaws.com	HTTPS	
		rds-fips.us-west-1.api.aws	HTTPS	
US West (Oregon)	us-west-2	rds.us-west-2.amazonaws.com	HTTPS	
		rds-fips.us-west-2.amazonaws.com	HTTPS	
		rds.us-west-2.api.aws	HTTPS	
		rds-fips.us-west-2.api.aws	HTTPS	
Africa (Cape Town)	af-south-1	rds.af-south-1.amazonaws.com	HTTPS	
		rds.af-south-1.api.aws	HTTPS	
Asia Pacific	ap-east-1	rds.ap-east-1.amazonaws.com	HTTPS	
		rds.ap-east-1.api.aws	HTTPS	

Region Name	Region	Endpoint	Protocol	
(Hong Kong)				
Asia Pacific (Hyderabad)	ap-south-2	rds.ap-south-2.amazonaws.com	HTTPS	
Asia Pacific (Jakarta)	ap-southeast-3	rds.ap-southeast-3.amazonaws.com	HTTPS	
Asia Pacific (Mumbai)	ap-south-1	rds.ap-south-1.amazonaws.com rds.ap-south-1.api.aws	HTTPS HTTPS	
Asia Pacific (Osaka)	ap-northeast-3	rds.ap-northeast-3.amazonaws.com rds.ap-northeast-3.api.aws	HTTPS HTTPS	
Asia Pacific (Seoul)	ap-northeast-2	rds.ap-northeast-2.amazonaws.com rds.ap-northeast-2.api.aws	HTTPS HTTPS	
Asia Pacific (Singapore)	ap-southeast-1	rds.ap-southeast-1.amazonaws.com rds.ap-southeast-1.api.aws	HTTPS HTTPS	
Asia Pacific (Sydney)	ap-southeast-2	rds.ap-southeast-2.amazonaws.com rds.ap-southeast-2.api.aws	HTTPS HTTPS	
Asia Pacific (Tokyo)	ap-northeast-1	rds.ap-northeast-1.amazonaws.com rds.ap-northeast-1.api.aws	HTTPS HTTPS	
Canada (Central)	ca-central-1	rds.ca-central-1.amazonaws.com rds.ca-central-1.api.aws rds-fips.ca-central-1.api.aws rds-fips.ca-central-1.amazonaws.com	HTTPS HTTPS HTTPS HTTPS	
Europe (Frankfurt)	eu-central-1	rds.eu-central-1.amazonaws.com rds.eu-central-1.api.aws	HTTPS HTTPS	
Europe (Ireland)	eu-west-1	rds.eu-west-1.amazonaws.com rds.eu-west-1.api.aws	HTTPS HTTPS	
Europe (London)	eu-west-2	rds.eu-west-2.amazonaws.com rds.eu-west-2.api.aws	HTTPS HTTPS

Region Name	Region	Endpoint	Protocol	
Europe (Paris)	eu-west-3	rds.eu-west-3.amazonaws.com rds.eu-west-3.api.aws	HTTPS HTTPS	
Europe (Spain)	eu-south-2	rds.eu-south-2.amazonaws.com	HTTPS	
Europe (Stockholm)	eu-north-1	rds.eu-north-1.amazonaws.com rds.eu-north-1.api.aws	HTTPS HTTPS	
Europe (Zurich)	eu-central-2	rds.eu-central-2.amazonaws.com	HTTPS	
Middle East (Bahrain)	me-south-1	rds.me-south-1.amazonaws.com rds.me-south-1.api.aws	HTTPS HTTPS	
Middle East (UAE)	me-central-1	rds.me-central-1.amazonaws.com	HTTPS	
South America (São Paulo)	sa-east-1	rds.sa-east-1.amazonaws.com rds.sa-east-1.api.aws	HTTPS HTTPS	
AWS GovCloud (US-East)	us-gov-east-1	rds.us-gov-east-1.amazonaws.com	HTTPS	
AWS GovCloud (US-West)	us-gov-west-1	rds.us-gov-west-1.amazonaws.com	HTTPS	

The following table shows the format that you should use when constructing an ARN for a particular Amazon RDS resource type.

Resource type	ARN format
DB instance	<p>arn:aws:rds:<region>:<account>:db:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:db:my-mysql-instance-1</pre>
DB cluster	<p>arn:aws:rds:<region>:<account>:cluster:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:cluster:my-aurora-cluster-1</pre>
Event subscription	arn:aws:rds:<region>:<account>:es:<name>

Resource type	ARN format
	For example: <div style="border: 1px solid black; padding: 5px; background-color: #f9f9f9;"> arn:aws:rds:us-east-2:123456789012:es:my-subscription </div>
DB option group	arn:aws:rds:<region>:<account>:og:<name> For example: <div style="border: 1px solid black; padding: 5px; background-color: #f9f9f9;"> arn:aws:rds:us-east-2:123456789012:og:my-og </div>
DB parameter group	arn:aws:rds:<region>:<account>:pg:<name> For example: <div style="border: 1px solid black; padding: 5px; background-color: #f9f9f9;"> arn:aws:rds:us-east-2:123456789012:pg:my-param-enable-logs </div>
DB cluster parameter group	arn:aws:rds:<region>:<account>:cluster-pg:<name> For example: <div style="border: 1px solid black; padding: 5px; background-color: #f9f9f9;"> arn:aws:rds:us-east-2:123456789012:cluster-pg:my-cluster-param-timezone </div>
Reserved DB instance	arn:aws:rds:<region>:<account>:ri:<name> For example: <div style="border: 1px solid black; padding: 5px; background-color: #f9f9f9;"> arn:aws:rds:us-east-2:123456789012:ri:my-reserved-postgresql </div>
DB security group	arn:aws:rds:<region>:<account>:secgrp:<name> For example: <div style="border: 1px solid black; padding: 5px; background-color: #f9f9f9;"> arn:aws:rds:us-east-2:123456789012:secgrp:my-public </div>
Automated DB snapshot	arn:aws:rds:<region>:<account>:snapshot:rds:<name> For example: <div style="border: 1px solid black; padding: 5px; background-color: #f9f9f9;"> arn:aws:rds:us-east-2:123456789012:snapshot:rds:my-mysql-db-2019-07-22-07-23 </div>
Automated DB cluster snapshot	arn:aws:rds:<region>:<account>:cluster-snapshot:rds:<name> For example: <div style="border: 1px solid black; padding: 5px; background-color: #f9f9f9;"> arn:aws:rds:us-east-2:123456789012:cluster-snapshot:rds:my-aurora-cluster-2019-07-22-16-16 </div>

Resource type	ARN format
Manual DB snapshot	<p>arn:aws:rds:<region>:<account>:snapshot:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:snapshot:my-mysql-db-snap</pre>
Manual DB cluster snapshot	<p>arn:aws:rds:<region>:<account>:cluster-snapshot:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:cluster-snapshot:my-aurora-cluster-snap</pre>
DB subnet group	<p>arn:aws:rds:<region>:<account>:subgrp:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:subgrp:my-subnet-10</pre>

Getting an existing ARN

You can get the ARN of an RDS resource by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or RDS API.

Console

To get an ARN from the AWS Management Console, navigate to the resource you want an ARN for, and view the details for that resource. For example, you can get the ARN for a DB instance from the **Configuration** tab of the DB instance details, as shown following.

The screenshot shows the 'Configuration' tab selected in the top navigation bar. Below it, the 'Instance' section is expanded, showing various configuration details. The 'ARN' field, which contains the value 'arn:aws:rds:us-west-2:XXXXXXXXXX:db:oracle-instance1', is highlighted with a large red oval.

DB instance id	oracle-instance1
Engine version	12.1.0.2.v14
Storage type	General Purpose (SSD)
IOPS	-
Storage	20 GiB
DB name	ORCL
License model	Bring Your Own License
Character set	AL32UTF8
Option groups	default:oracle-ee-12-1
ARN	arn:aws:rds:us-west-2:XXXXXXXXXX:db:oracle-instance1
Resource id	XXXXXXXXXX

AWS CLI

To get an ARN from the AWS CLI for a particular RDS resource, you use the `describe` command for that resource. The following table shows each AWS CLI command, and the ARN property used with the command to get an ARN.

AWS CLI command	ARN property
<code>describe-event-subscriptions</code>	<code>EventSubscriptionArn</code>
<code>describe-certificates</code>	<code>CertificateArn</code>

AWS CLI command	ARN property
describe-db-parameter-groups	DBParameterGroupArn
describe-db-cluster-parameter-groups	DBClusterParameterGroupArn
describe-db-instances	DBInstanceArn
describe-db-security-groups	DBSecurityGroupArn
describe-db-snapshots	DBSnapshotArn
describe-events	SourceArn
describe-reserved-db-instances	ReservedDBInstanceArn
describe-db-subnet-groups	DBSubnetGroupArn
describe-option-groups	OptionGroupArn
describe-db-clusters	DBClusterArn
describe-db-cluster-snapshots	DBClusterSnapshotArn

For example, the following AWS CLI command gets the ARN for a DB instance.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
--db-instance-identifier DBInstanceIdentifier \
--region us-west-2 \
--query "*[].[DBInstanceIdentifier,DBInstanceArn,DBInstanceArn]"
```

For Windows:

```
aws rds describe-db-instances ^
--db-instance-identifier DBInstanceIdentifier ^
--region us-west-2 ^
--query "*[].[DBInstanceIdentifier,DBInstanceArn,DBInstanceArn]"
```

The output of that command is like the following:

```
[  
  {  
    "DBInstanceArn": "arn:aws:rds:us-west-2:account_id:db:instance_id",  
    "DBInstanceIdentifier": "instance_id"  
  }  
]
```

RDS API

To get an ARN for a particular RDS resource, you can call the following RDS API operations and use the ARN properties shown following.

RDS API operation	ARN property
DescribeEventSubscriptions	EventSubscriptionArn
DescribeCertificates	CertificateArn
DescribeDBParameterGroups	DBParameterGroupArn
DescribeDBClusterParameterGroups	DBClusterParameterGroupArn
DescribeDBInstances	DBInstanceArn
DescribeDBSecurityGroups	DBSecurityGroupArn
DescribeDBSchemas	DBSnapshotArn
DescribeEvents	SourceArn
DescribeReservedDBInstances	ReservedDBInstanceArn
DescribeDBSubnetGroups	DBSubnetGroupArn
DescribeOptionGroups	OptionGroupArn
DescribeDBClusters	DBClusterArn
DescribeDBClusterSnapshots	DBClusterSnapshotArn

Working with storage for Amazon RDS DB instances

To specify how you want your data stored in Amazon RDS, choose a storage type and provide a storage size when you create or modify a DB instance. Later, you can increase the amount or change the type of storage by modifying the DB instance. For more information about which storage type to use for your workload, see [Amazon RDS storage types \(p. 64\)](#).

Topics

- [Increasing DB instance storage capacity \(p. 410\)](#)
- [Managing capacity automatically with Amazon RDS storage autoscaling \(p. 412\)](#)
- [Modifying settings for Provisioned IOPS SSD storage \(p. 416\)](#)
- [I/O-intensive storage modifications \(p. 418\)](#)
- [Modifying settings for General Purpose SSD \(gp3\) storage \(p. 418\)](#)

Increasing DB instance storage capacity

If you need space for additional data, you can scale up the storage of an existing DB instance. To do so, you can use the Amazon RDS Management Console, the Amazon RDS API, or the AWS Command Line Interface (AWS CLI). For information about storage limits, see [Amazon RDS DB instance storage \(p. 64\)](#).

Note

Scaling storage for Amazon RDS for Microsoft SQL Server DB instances is supported only for General Purpose SSD or Provisioned IOPS SSD storage types.

To monitor the amount of free storage for your DB instance so you can respond when necessary, we recommend that you create an Amazon CloudWatch alarm. For more information on setting CloudWatch alarms, see [Using CloudWatch alarms](#).

Scaling storage usually doesn't cause any outage or performance degradation of the DB instance. After you modify the storage size for a DB instance, the status of the DB instance is **storage-optimization**.

Note

Storage optimization can take several hours. You can't make further storage modifications for either six (6) hours or until storage optimization has completed on the instance, whichever is longer.

However, a special case is if you have a SQL Server DB instance and haven't modified the storage configuration since November 2017. In this case, you might experience a short outage of a few minutes when you modify your DB instance to increase the allocated storage. After the outage, the DB instance is online but in the **storage-optimization** state. Performance might be degraded during storage optimization.

Note

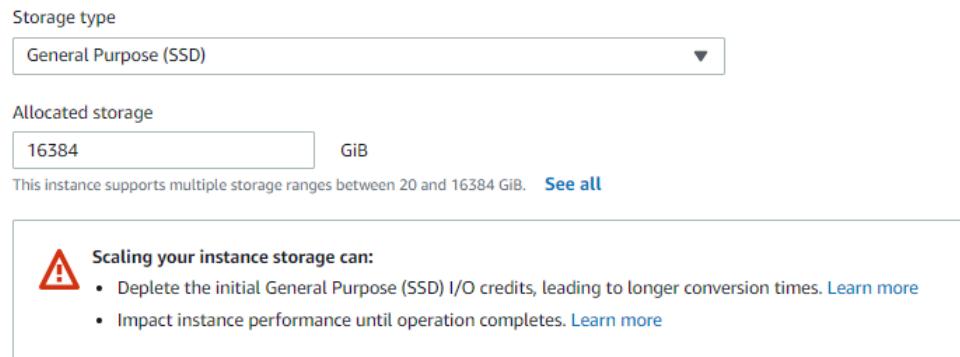

You can't reduce the amount of storage for a DB instance after storage has been allocated. When you increase the allocated storage, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error.

Console

To increase storage for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Enter a new value for **Allocated storage**. It must be greater than the current value.

6. Choose **Continue** to move to the next screen.
7. Choose **Apply immediately** in the **Scheduling of modifications** section to apply the storage changes to the DB instance immediately.
Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.
8. When the settings are as you want them, choose **Modify DB instance**.

AWS CLI

To increase the storage for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameters:

- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `--apply-immediately` – Use `--apply-immediately` to apply the storage changes immediately.
Or use `--no-apply-immediately` (the default) to apply the changes during the next maintenance window. An immediate outage occurs when the changes are applied.

For more information about storage, see [Amazon RDS DB instance storage \(p. 64\)](#).

RDS API

To increase storage for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameters:

- `AllocatedStorage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `ApplyImmediately` – Set this option to `True` to apply the storage changes immediately. Set this option to `False` (the default) to apply the changes during the next maintenance window. An immediate outage occurs when the changes are applied.

For more information about storage, see [Amazon RDS DB instance storage \(p. 64\)](#).

Managing capacity automatically with Amazon RDS storage autoscaling

If your workload is unpredictable, you can enable storage autoscaling for an Amazon RDS DB instance. To do so, you can use the Amazon RDS console, the Amazon RDS API, or the AWS CLI.

For example, you might use this feature for a new mobile gaming application that users are adopting rapidly. In this case, a rapidly increasing workload might exceed the available database storage. To avoid having to manually scale up database storage, you can use Amazon RDS storage autoscaling.

With storage autoscaling enabled, when Amazon RDS detects that you are running out of free database space it automatically scales up your storage. Amazon RDS starts a storage modification for an autoscaling-enabled DB instance when these factors apply:

- Free available space is less than 10 percent of the allocated storage.
- The low-storage condition lasts at least five minutes.
- At least six hours have passed since the last storage modification, or storage optimization has completed on the instance, whichever is longer.

The additional storage is in increments of whichever of the following is greater:

- 5 GiB
- 10 percent of currently allocated storage
- Storage growth prediction for 7 hours based on the `FreeStorageSpace` metrics change in the past hour. For more information on metrics, see [Monitoring with Amazon CloudWatch](#).

The maximum storage threshold is the limit that you set for autoscaling the DB instance. It has the following constraints:

- You must set the maximum storage threshold to at least 10% more than the current allocated storage. We recommend setting it to at least 26% more to avoid receiving an [event notification \(p. 674\)](#) that the storage size is approaching the maximum storage threshold.

For example, if you have DB instance with 1000 GiB of allocated storage, then set the maximum storage threshold to at least 1100 GiB. If you don't, you get an error such as Invalid max storage size for `engine_name`. However, we recommend that you set the maximum storage threshold to at least 1260 GiB to avoid the event notification.

- For a DB instance that uses Provisioned IOPS storage, the ratio of IOPS to maximum storage threshold (in GiB) must be from 1–50 on RDS for SQL Server, and 0.5–50 on other RDS DB engines.
- You can't set the maximum storage threshold for autoscaling-enabled instances to a value greater than the maximum allocated storage for the database engine and DB instance class.

For example, SQL Server Standard Edition on db.m5.xlarge has a default allocated storage for the instance of 20 GiB (the minimum) and a maximum allocated storage of 16,384 GiB. The default maximum storage threshold for autoscaling is 1,000 GiB. If you use this default, the instance doesn't autoscale above 1,000 GiB. This is true even though the maximum allocated storage for the instance is 16,384 GiB.

Note

We recommend that you carefully choose the maximum storage threshold based on usage patterns and customer needs. If there are any aberrations in the usage patterns, the maximum storage threshold can prevent scaling storage to an unexpectedly high value when autoscaling

predicts a very high threshold. After a DB instance has been autoscaled, its allocated storage can't be reduced.

Topics

- [Limitations \(p. 413\)](#)
- [Enabling storage autoscaling for a new DB instance \(p. 413\)](#)
- [Changing the storage autoscaling settings for a DB instance \(p. 414\)](#)
- [Turning off storage autoscaling for a DB instance \(p. 415\)](#)

Limitations

The following limitations apply to storage autoscaling:

- Autoscaling doesn't occur if the maximum storage threshold would be equaled or exceeded by the storage increment.
- When autoscaling, RDS predicts the storage size for subsequent autoscaling operations. If a subsequent operation is predicted to exceed the maximum storage threshold, then RDS autoscales to the maximum storage threshold.
- Autoscaling can't completely prevent storage-full situations for large data loads. This is because further storage modifications can't be made for either six (6) hours or until storage optimization has completed on the instance, whichever is longer.

If you perform a large data load, and autoscaling doesn't provide enough space, the database might remain in the storage-full state for several hours. This can harm the database.

- If you start a storage scaling operation at the same time that Amazon RDS starts an autoscaling operation, your storage modification takes precedence. The autoscaling operation is canceled.
- Autoscaling can't be used with magnetic storage.
- Autoscaling can't be used with the following previous-generation instance classes that have less than 6 TiB of orderable storage: db.m3.large, db.m3.xlarge, and db.m3.2xlarge.
- Autoscaling operations aren't logged by AWS CloudTrail. For more information on CloudTrail, see [Monitoring Amazon RDS API calls in AWS CloudTrail \(p. 725\)](#).

Although automatic scaling helps you to increase storage on your Amazon RDS DB instance dynamically, you should still configure the initial storage for your DB instance to an appropriate size for your typical workload.

Enabling storage autoscaling for a new DB instance

When you create a new Amazon RDS DB instance, you can choose whether to enable storage autoscaling. You can also set an upper limit on the storage that Amazon RDS can allocate for the DB instance.

Note

When you clone an Amazon RDS DB instance that has storage autoscaling enabled, that setting isn't automatically inherited by the cloned instance. The new DB instance has the same amount of allocated storage as the original instance. You can turn storage autoscaling on again for the new instance if the cloned instance continues to increase its storage requirements.

Console

To enable storage autoscaling for a new DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**. On the **Select engine** page, choose your database engine and specify your DB instance information as described in [Getting started with Amazon RDS \(p. 153\)](#).
5. In the **Storage autoscaling** section, set the **Maximum storage threshold** value for the DB instance.
6. Specify the rest of your DB instance information as described in [Getting started with Amazon RDS \(p. 153\)](#).

AWS CLI

To enable storage autoscaling for a new DB instance, use the AWS CLI command [create-db-instance](#). Set the following parameter:

- `--max-allocated-storage` – Turns on storage autoscaling and sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the AWS CLI [describe-valid-db-instance-modifications](#) command. To check based on the instance class before creating an instance, use the [describe-orderable-db-instance-options](#) command. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance or instance class supports storage autoscaling.

For more information about storage, see [Amazon RDS DB instance storage \(p. 64\)](#).

RDS API

To enable storage autoscaling for a new DB instance, use the Amazon RDS API operation [CreateDBInstance](#). Set the following parameter:

- `MaxAllocatedStorage` – Turns on Amazon RDS storage autoscaling and sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the Amazon RDS API [DescribeValidDbInstanceModifications](#) operation for an existing instance, or the [DescribeOrderableDBInstanceOptions](#) operation before creating an instance. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see [Amazon RDS DB instance storage \(p. 64\)](#).

Changing the storage autoscaling settings for a DB instance

You can turn storage autoscaling on for an existing Amazon RDS DB instance. You can also change the upper limit on the storage that Amazon RDS can allocate for the DB instance.

Console

To change the storage autoscaling settings for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify, and choose **Modify**. The **Modify DB instance** page appears.
4. Change the storage limit in the **Autoscaling** section. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).
5. When all the changes are as you want them, choose **Continue** and check your modifications.
6. On the confirmation page, review your changes. If they're correct, choose **Modify DB Instance** to save your changes. If they aren't correct, choose **Back** to edit your changes or **Cancel** to cancel your changes.

Changing the storage autoscaling limit occurs immediately. This setting ignores the **Apply immediately** setting.

AWS CLI

To change the storage autoscaling settings for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameter:

- `--max-allocated-storage` – Sets the upper limit on storage size, in gibibytes. If the value is greater than the `--allocated-storage` parameter, storage autoscaling is turned on. If the value is the same as the `--allocated-storage` parameter, storage autoscaling is turned off.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the AWS CLI `describe-valid-db-instance-modifications` command. To check based on the instance class before creating an instance, use the `describe-orderable-db-instance-options` command. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see [Amazon RDS DB instance storage \(p. 64\)](#).

RDS API

To change the storage autoscaling settings for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameter:

- `MaxAllocatedStorage` – Sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the Amazon RDS API `DescribeValidDbInstanceModifications` operation for an existing instance, or the `DescribeOrderableDBInstanceOptions` operation before creating an instance. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see [Amazon RDS DB instance storage \(p. 64\)](#).

Turning off storage autoscaling for a DB instance

If you no longer need Amazon RDS to automatically increase the storage for an Amazon RDS DB instance, you can turn off storage autoscaling. After you do, you can still manually increase the amount of storage for your DB instance.

Console

To turn off storage autoscaling for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify and choose **Modify**. The **Modify DB instance** page appears.
4. Clear the **Enable storage autoscaling** check box in the **Storage autoscaling** section. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).
5. When all the changes are as you want them, choose **Continue** and check the modifications.
6. On the confirmation page, review your changes. If they're correct, choose **Modify DB Instance** to save your changes. If they aren't correct, choose **Back** to edit your changes or **Cancel** to cancel your changes.

Changing the storage autoscaling limit occurs immediately. This setting ignores the **Apply immediately** setting.

AWS CLI

To turn off storage autoscaling for a DB instance, use the AWS CLI command `modify-db-instance` and the following parameter:

- `--max-allocated-storage` – Specify a value equal to the `--allocated-storage` setting to prevent further Amazon RDS storage autoscaling for the specified DB instance.

For more information about storage, see [Amazon RDS DB instance storage \(p. 64\)](#).

RDS API

To turn off storage autoscaling for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameter:

- `MaxAllocatedStorage` – Specify a value equal to the `AllocatedStorage` setting to prevent further Amazon RDS storage autoscaling for the specified DB instance.

For more information about storage, see [Amazon RDS DB instance storage \(p. 64\)](#).

Modifying settings for Provisioned IOPS SSD storage

You can modify the settings for a DB instance that uses Provisioned IOPS SSD storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. Specify the storage type, allocated storage, and the amount of Provisioned IOPS that you require. The range depends on your database engine and instance type.

Although you can reduce the amount of IOPS provisioned for your instance, you can't reduce the storage size.

In most cases, scaling storage doesn't require any outage and doesn't degrade performance of the server. After you modify the storage IOPS for a DB instance, the status of the DB instance is **storage-optimization**.

Note

Storage optimization can take several hours. You can't make further storage modifications for either six (6) hours or until storage optimization has completed on the instance, whichever is longer.

For information on the ranges of allocated storage and Provisioned IOPS available for each database engine, see [Provisioned IOPS SSD storage \(p. 66\)](#).

Console

To change the Provisioned IOPS settings for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

To filter the list of DB instances, for **Filter databases** enter a text string for Amazon RDS to use to filter the results. Only DB instances whose names contain the string appear.

3. Choose the DB instance with Provisioned IOPS that you want to modify.
4. Choose **Modify**.
5. On the **Modify DB instance** page, choose **Provisioned IOPS SSD (io1)** for **Storage type**.
6. For **Provisioned IOPS**, enter a value.

If the value that you specify for either **Allocated storage** or **Provisioned IOPS** is outside the limits supported by the other parameter, a warning message is displayed. This message gives the range of values required for the other parameter.

7. Choose **Continue**.
8. Choose **Apply immediately** in the **Scheduling of modifications** section to apply the changes to the DB instance immediately. Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.

An immediate outage occurs when the storage type changes. For more information about storage, see [Amazon RDS DB instance storage \(p. 64\)](#).

9. Review the parameters to be changed, and choose **Modify DB instance** to complete the modification.

The new value for allocated storage or for Provisioned IOPS appears in the **Status** column.

AWS CLI

To change the Provisioned IOPS setting for a DB instance, use the AWS CLI command [modify-db-instance](#). Set the following parameters:

- **--storage-type** – Set to **io1** for Provisioned IOPS.
- **--allocated-storage** – Amount of storage to be allocated for the DB instance, in gibibytes.
- **--iops** – The new amount of Provisioned IOPS for the DB instance, expressed in I/O operations per second.
- **--apply-immediately** – Use **--apply-immediately** to apply changes immediately. Use **--no-apply-immediately** (the default) to apply changes during the next maintenance window.

RDS API

To change the Provisioned IOPS settings for a DB instance, use the Amazon RDS API operation [ModifyDBInstance](#). Set the following parameters:

- `StorageType` – Set to `io1` for Provisioned IOPS.
- `AllocatedStorage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `Iops` – The new IOPS rate for the DB instance, expressed in I/O operations per second.
- `ApplyImmediately` – Set this option to `True` to apply changes immediately. Set this option to `False` (the default) to apply changes during the next maintenance window.

I/O-intensive storage modifications

Amazon RDS DB instances use Amazon Elastic Block Store (EBS) volumes for database and log storage. Depending on the amount of storage requested, RDS (except for RDS for SQL Server) automatically *stripes* across multiple Amazon EBS volumes to enhance performance. RDS DB instances with SSD storage types are backed by either one or four striped Amazon EBS volumes in a RAID 0 configuration. By design, storage modification operations for an RDS DB instance have minimal impact on ongoing database operations.

In most cases, storage scaling modifications are completely offloaded to the Amazon EBS layer and are transparent to the database. This process is typically completed within a few minutes. However, some older RDS storage volumes require a different process for modifying the size, Provisioned IOPS, or storage type. This involves making a full copy of the data using a potentially I/O-intensive operation.

Storage modification uses an I/O-intensive operation if any of the following factors apply:

- The source storage type is magnetic. Magnetic storage doesn't support elastic volume modification.
- The RDS DB instance isn't on a one- or four-volume Amazon EBS layout. You can view the number of Amazon EBS volumes in use on your RDS DB instances by using Enhanced Monitoring metrics. For more information, see [Viewing OS metrics in the RDS console \(p. 605\)](#).
- The target size of the modification request increases the allocated storage above 400 GiB for RDS for MariaDB, MySQL, and PostgreSQL instances, and 200 GiB for RDS for Oracle. Storage autoscaling operations have the same effect when they increase the allocated storage size of your DB instance above these thresholds.

If your storage modification involves an I/O-intensive operation, it consumes I/O resources and increases the load on your DB instance. Storage modifications with I/O-intensive operations involving General Purpose SSD (gp2) storage can deplete your I/O credit balance, resulting in longer conversion times.

We recommend as a best practice to schedule these storage modification requests outside of peak hours to help reduce the time required to complete the storage modification operation. Alternatively, you can create a read replica of the DB instance and perform the storage modification on the read replica. Then promote the read replica to be the primary DB instance. For more information, see [Working with read replicas \(p. 370\)](#).

For more information, see [Why is an Amazon RDS DB instance stuck in the modifying state when I try to increase the allocated storage?](#)

Modifying settings for General Purpose SSD (gp3) storage

You can modify the settings for a DB instance that uses General Purpose SSD (gp3) storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. Specify the storage type, allocated storage, amount of Provisioned IOPS, and storage throughput that you require. Although you can reduce the amount of IOPS provisioned for your instance, you can't reduce the storage size.

In most cases, scaling storage doesn't require any outage. After you modify the storage IOPS for a DB instance, the status of the DB instance is **storage-optimization**. You can expect elevated latencies,

but still within the single-digit millisecond range, during storage optimization. The DB instance is fully operational after a storage modification.

Note

You can't make further storage modifications until six (6) hours after storage optimization has completed on the instance.

For information on the ranges of allocated storage, Provisioned IOPS, and storage throughput available for each database engine, see [gp3 storage \(p. 65\)](#).

Console

To change the storage performance settings for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

To filter the list of DB instances, for **Filter databases** enter a text string for Amazon RDS to use to filter the results. Only DB instances whose names contain the string appear.

3. Choose the DB instance with gp3 storage that you want to modify.
4. Choose **Modify**.
5. On the **Modify DB Instance page**, choose **General Purpose SSD (gp3)** for **Storage type**, then do the following:
 - a. For **Provisioned IOPS**, choose a value.
If the value that you specify for either **Allocated storage** or **Provisioned IOPS** is outside the limits supported by the other parameter, a warning message appears. This message gives the range of values required for the other parameter.
 - b. For **Storage throughput**, choose a value.
If the value that you specify for either **Provisioned IOPS** or **Storage throughput** is outside the limits supported by the other parameter, a warning message appears. This message gives the range of values required for the other parameter.
6. Choose **Continue**.
7. Choose **Apply immediately** in the **Scheduling of modifications** section to apply the changes to the DB instance immediately. Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.
An immediate outage occurs when the storage type changes. For more information about storage, see [Amazon RDS DB instance storage \(p. 64\)](#).
8. Review the parameters to be changed, and choose **Modify DB instance** to complete the modification.

The new value for Provisioned IOPS appears in the **Status** column.

AWS CLI

To change the storage performance settings for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameters:

- `--storage-type` – Set to gp3 for General Purpose SSD (gp3).
- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `--iops` – The new amount of Provisioned IOPS for the DB instance, expressed in I/O operations per second.

- **--storage-throughput** – The new storage throughput for the DB instance, expressed in MiBps.
- **--apply-immediately** – Use **--apply-immediately** to apply changes immediately. Use **--no-apply-immediately** (the default) to apply changes during the next maintenance window.

RDS API

To change the storage performance settings for a DB instance, use the Amazon RDS API operation [ModifyDBInstance](#). Set the following parameters:

- **StorageType** – Set to gp3 for General Purpose SSD (gp3).
- **AllocatedStorage** – Amount of storage to be allocated for the DB instance, in gibibytes.
- **Iops** – The new IOPS rate for the DB instance, expressed in I/O operations per second.
- **StorageThroughput** – The new storage throughput for the DB instance, expressed in MiBps.
- **ApplyImmediately** – Set this option to True to apply changes immediately. Set this option to False (the default) to apply changes during the next maintenance window.

Deleting a DB instance

To delete a DB instance, you must do the following:

- Provide the name of the instance
- Enable or disable the option to take a final DB snapshot of the instance
- Enable or disable the option to retain automated backups

If you delete a DB instance that has read replicas in the same AWS Region, each read replica is promoted to a standalone DB instance. For more information, see [Promoting a read replica to be a standalone DB instance \(p. 377\)](#). If your DB instance has read replicas in different AWS Regions, see [Cross-Region replication considerations \(p. 387\)](#) for information related to deleting the source DB instance for a cross-Region read replica.

Note

When the status for a DB instance is `deleting`, its CA certificate value doesn't appear in the RDS console or in output for AWS CLI commands or RDS API operations. For more information about CA certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 2005\)](#).

Deletion protection

You can only delete instances that don't have deletion protection enabled. When you create or modify a DB instance, you have the option to enable deletion protection so that users can't delete the DB instance. Deletion protection is disabled by default for you when you use AWS CLI and API commands. Deletion protection is enabled for you when you use the AWS Management Console to create a production DB instance. However, Amazon RDS enforces deletion protection when you use the console, the CLI, or the API to delete a DB instance. To delete a DB instance that has deletion protection enabled, first modify the instance and disable deletion protection. Enabling or disabling deletion protection doesn't cause an outage.

Creating a final snapshot and retaining automated backups

When you delete a DB instance, you can choose to do one or both of the following:

- Create a final DB snapshot.
 - To be able to restore your deleted DB instance later, create a final DB snapshot. The final snapshot is retained, along with any manual snapshots that were taken.
 - To delete a DB instance quickly, you can skip creating a final DB snapshot.

Note

You can't create a final DB snapshot of your DB instance if it has the status `creating`, `failed`, `incompatible-restore`, or `incompatible-network`. For more information, see [Viewing Amazon RDS DB instance status \(p. 516\)](#).

- Retain automated backups.
 - Your automated backups are retained for the retention period that is set on the DB instance at the time when you delete it. This set retention period occurs whether or not you choose to create a final DB snapshot.
 - If you don't choose to retain automated backups, your automated backups in the same AWS Region as the DB instance are deleted. They can't be recovered after you delete the DB instance.

Note

Automated backups that are replicated to another AWS Region are retained even if you choose not to retain automated backups. For more information, see [Replicating automated backups to another AWS Region \(p. 437\)](#).

- You typically don't need to retain automated backups if you create a final DB snapshot.
- To delete a retained automated backup, follow the instructions in [Deleting retained automated backups \(p. 433\)](#).

Important

If you skip the final DB snapshot, to restore your DB instance do one of the following:

- Use an earlier manual snapshot of the DB instance to restore the DB instance to that DB snapshot's point in time.
- Retain automated backups. You can use them to restore your DB instance during your retention period, but not after your retention period has ended.

Note

Regardless of your choice, manual DB snapshots aren't deleted. For more information on snapshots, see [Creating a DB snapshot \(p. 448\)](#).

Deleting a DB instance

You can delete a DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

The time required to delete a DB instance can vary depending on the backup retention period (that is, how many backups to delete), how much data is deleted, and whether a final snapshot is taken.

Note

You can't delete a DB instance when deletion protection is enabled for it. For more information, see [Deletion protection \(p. 421\)](#).

You can disable deletion protection by modifying the DB instance. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

Console

To delete a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to delete.
3. For **Actions**, choose **Delete**.
4. To create a final DB snapshot for the DB instance, choose **Create final snapshot?**.
5. If you chose to create a final snapshot, enter the **Final snapshot name**.
6. To retain automated backups, choose **Retain automated backups**.
7. Enter **delete me** in the box.
8. Choose **Delete**.

AWS CLI

To delete a DB instance by using the AWS CLI, call the `delete-db-instance` command with the following options:

- `--db-instance-identifier`

- `--final-db-snapshot-identifier` or `--skip-final-snapshot`

Example With a final snapshot and no retained automated backups

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
  --db-instance-identifier mydbinstance \
  --final-db-snapshot-identifier mydbinstancefinalsnapshot \
  --delete-automated-backups
```

For Windows:

```
aws rds delete-db-instance ^
  --db-instance-identifier mydbinstance ^
  --final-db-snapshot-identifier mydbinstancefinalsnapshot ^
  --delete-automated-backups
```

Example With retained automated backups and no final snapshot

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
  --db-instance-identifier mydbinstance \
  --skip-final-snapshot \
  --no-delete-automated-backups
```

For Windows:

```
aws rds delete-db-instance ^
  --db-instance-identifier mydbinstance ^
  --skip-final-snapshot ^
  --no-delete-automated-backups
```

RDS API

To delete a DB instance by using the Amazon RDS API, call the [DeleteDBInstance](#) operation with the following parameters:

- `DBInstanceIdentifier`
- `FinalDBSnapshotIdentifier` or `SkipFinalSnapshot`

Deleting a Multi-AZ DB cluster

You can delete a DB Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

The time required to delete a Multi-AZ DB cluster can vary depending on certain factors. These are the backup retention period (that is, how many backups to delete), how much data is deleted, and whether a final snapshot is taken.

You can't delete a Multi-AZ DB cluster when deletion protection is turned on for it. For more information, see [Deletion protection \(p. 421\)](#). You can turn off deletion protection by modifying the Multi-AZ DB cluster. For more information, see [Modifying a Multi-AZ DB cluster \(p. 341\)](#).

Console

To delete a Multi-AZ DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the Multi-AZ DB cluster that you want to delete.
3. For **Actions**, choose **Delete**.
4. Choose **Create final snapshot?** to create a final DB snapshot for the Multi-AZ DB cluster.
If you create a final snapshot, enter a name for **Final snapshot name**.
5. Choose **Retain automated backups** to retain automated backups.
6. Enter **delete me** in the box.
7. Choose **Delete**.

AWS CLI

To delete a Multi-AZ DB cluster by using the AWS CLI, call the `delete-db-cluster` command with the following options:

- `--db-cluster-identifier`
- `--final-db-snapshot-identifier` or `--skip-final-snapshot`

Example With a final snapshot

For Linux, macOS, or Unix:

```
aws rds delete-db-cluster \
--db-cluster-identifier mymultiazdbcluster \
--final-db-snapshot-identifier mymultiazdbclusterfinalsnapshot
```

For Windows:

```
aws rds delete-db-cluster ^
--db-cluster-identifier mymultiazdbcluster ^
--final-db-snapshot-identifier mymultiazdbclusterfinalsnapshot
```

Example With no final snapshot

For Linux, macOS, or Unix:

```
aws rds delete-db-cluster \
--db-cluster-identifier mymultiazdbcluster \
--skip-final-snapshot
```

For Windows:

```
aws rds delete-db-cluster ^
--db-cluster-identifier mymultiazdbcluster ^
--skip-final-snapshot
```

RDS API

To delete a Multi-AZ DB cluster by using the Amazon RDS API, call the [DeleteDBCluster](#) operation with the following parameters:

- `DBClusterIdentifier`
- `FinalDBSnapshotIdentifier` or `SkipFinalSnapshot`

Backing up and restoring an Amazon RDS DB instance

This section shows how to back up and restore a DB instance.

Working with backups

Amazon RDS creates and saves automated backups of your DB instance during the backup window of your DB instance. RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. RDS saves the automated backups of your DB instance according to the backup retention period that you specify. If necessary, you can recover your database to any point in time during the backup retention period.

Automated backups follow these rules:

- Your DB instance must be in the available state for automated backups to occur. Automated backups don't occur while your DB instance is in a state other than available, for example `storage_full`.
- Automated backups don't occur while a DB snapshot copy is running in the same AWS Region for the same DB instance.

You can also back up your DB instance manually, by manually creating a DB snapshot. For more information about creating a DB snapshot, see [Creating a DB snapshot \(p. 448\)](#).

The first snapshot of a DB instance contains the data for the full DB instance. Subsequent snapshots of the same DB instance are incremental, which means that only the data that has changed after your most recent snapshot is saved.

You can copy both automatic and manual DB snapshots, and share manual DB snapshots. For more information about copying a DB snapshot, see [Copying a DB snapshot \(p. 458\)](#). For more information about sharing a DB snapshot, see [Sharing a DB snapshot \(p. 472\)](#).

Backup storage

Your Amazon RDS backup storage for each AWS Region is composed of the automated backups and manual DB snapshots for that Region. Total backup storage space equals the sum of the storage for all backups in that Region. Moving a DB snapshot to another Region increases the backup storage in the destination Region. Backups are stored in Amazon S3.

For more information about backup storage costs, see [Amazon RDS pricing](#).

If you chose to retain automated backups when you delete a DB instance, the automated backups are saved for the full retention period. If you don't choose **Retain automated backups** when you delete a DB instance, all automated backups are deleted with the DB instance. After they are deleted, the automated backups can't be recovered. If you choose to have Amazon RDS create a final DB snapshot before it

deletes your DB instance, you can use that to recover your DB instance. Or you can use a previously created manual snapshot. Manual snapshots are not deleted. You can have up to 100 manual snapshots per Region.

Backup window

Automated backups occur daily during the preferred backup window. If the backup requires more time than allotted to the backup window, the backup continues after the window ends, until it finishes. The backup window can't overlap with the weekly maintenance window for the DB instance.

During the automatic backup window, storage I/O might be suspended briefly while the backup process initializes (typically under a few seconds). You might experience elevated latencies for a few minutes during backups for Multi-AZ deployments. For MariaDB, MySQL, Oracle, and PostgreSQL, I/O activity isn't suspended on your primary during backup for Multi-AZ deployments, because the backup is taken from the standby. For SQL Server, I/O activity is suspended briefly during backup for both Single-AZ and Multi-AZ deployments, because the backup is taken from the primary.

Automated backups might occasionally be skipped if the DB instance has a heavy workload at the time a backup is supposed to start. If a backup is skipped, you can still do a point-in-time-recovery (PITR), and a backup is still attempted during the next backup window. For more information on PITR, see [Restoring a DB instance to a specified time \(p. 499\)](#).

If you don't specify a preferred backup window when you create the DB instance, Amazon RDS assigns a default 30-minute backup window. This window is selected at random from an 8-hour block of time for each AWS Region. The following table lists the time blocks for each AWS Region from which the default backup windows are assigned.

Region Name	Region	Time Block
US East (Ohio)	us-east-2	03:00–11:00 UTC
US East (N. Virginia)	us-east-1	03:00–11:00 UTC
US West (N. California)	us-west-1	06:00–14:00 UTC
US West (Oregon)	us-west-2	06:00–14:00 UTC
Africa (Cape Town)	af-south-1	03:00–11:00 UTC
Asia Pacific (Hong Kong)	ap-east-1	06:00–14:00 UTC
Asia Pacific (Hyderabad)	ap-south-2	06:30–14:30 UTC
Asia Pacific (Jakarta)	ap-southeast-3	08:00–16:00 UTC
Asia Pacific (Mumbai)	ap-south-1	16:30–00:30 UTC
Asia Pacific (Osaka)	ap-northeast-3	00:00–08:00 UTC
Asia Pacific (Seoul)	ap-northeast-2	13:00–21:00 UTC
Asia Pacific (Singapore)	ap-southeast-1	14:00–22:00 UTC
Asia Pacific (Sydney)	ap-southeast-2	12:00–20:00 UTC
Asia Pacific (Tokyo)	ap-northeast-1	13:00–21:00 UTC
Canada (Central)	ca-central-1	03:00–11:00 UTC

Region Name	Region	Time Block
China (Beijing)	cn-north-1	06:00–14:00 UTC
China (Ningxia)	cn-northwest-1	06:00–14:00 UTC
Europe (Frankfurt)	eu-central-1	20:00–04:00 UTC
Europe (Ireland)	eu-west-1	22:00–06:00 UTC
Europe (London)	eu-west-2	22:00–06:00 UTC
Europe (Milan)	eu-south-1	02:00–10:00 UTC
Europe (Paris)	eu-west-3	07:29–14:29 UTC
Europe (Spain)	eu-south-2	02:00–10:00 UTC
Europe (Stockholm)	eu-north-1	23:00–07:00 UTC
Europe (Zurich)	eu-central-2	02:00–10:00 UTC
Middle East (Bahrain)	me-south-1	06:00–14:00 UTC
Middle East (UAE)	me-central-1	05:00–13:00 UTC
South America (São Paulo)	sa-east-1	23:00–07:00 UTC
AWS GovCloud (US-East)	us-gov-east-1	17:00–01:00 UTC
AWS GovCloud (US-West)	us-gov-west-1	06:00–14:00 UTC

Backup retention period

You can set the backup retention period when you create a DB instance. If you don't set the backup retention period, the default backup retention period is one day if you create the DB instance using the Amazon RDS API or the AWS CLI. The default backup retention period is seven days if you create the DB instance using the console.

After you create a DB instance, you can modify the backup retention period. You can set the backup retention period to between 0 and 35 days. Setting the backup retention period to 0 disables automated backups. Manual snapshot limits (100 per Region) do not apply to automated backups.

Automated backups aren't created while a DB instance is stopped. Backups can be retained longer than the backup retention period if a DB instance has been stopped. RDS doesn't include time spent in the stopped state when the backup retention window is calculated.

Important

An outage occurs if you change the backup retention period from 0 to a nonzero value or from a nonzero value to 0. This applies to both Single-AZ and Multi-AZ DB instances.

Enabling automated backups

If your DB instance doesn't have automated backups enabled, you can enable them at any time. You enable automated backups by setting the backup retention period to a positive nonzero value. When

automated backups are enabled, your RDS instance and database is taken offline and a backup is immediately created.

Note

If you manage your backups in AWS Backup, you can't enable automated backups. For more information, see [Using AWS Backup to manage automated backups \(p. 435\)](#).

Console

To enable automated backups immediately

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **Backup retention period**, choose a positive nonzero value, for example 3 days.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. On the confirmation page, choose **Modify DB instance** to save your changes and enable automated backups.

AWS CLI

To enable automated backups, use the AWS CLI `modify-db-instance` command.

Include the following parameters:

- `--db-instance-identifier`
- `--backup-retention-period`
- `--apply-immediately` or `--no-apply-immediately`

In the following example, we enable automated backups by setting the backup retention period to three days. The changes are applied immediately.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --backup-retention-period 3 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --backup-retention-period 3 ^
  --apply-immediately
```

RDS API

To enable automated backups, use the RDS API `ModifyDBInstance` operation with the following required parameters:

- `DBInstanceIdentifier`
- `BackupRetentionPeriod`

Viewing automated backups

To view your automated backups, choose **Automated backups** in the navigation pane. To view individual snapshots associated with an automated backup, choose **Snapshots** in the navigation pane. Alternatively, you can describe individual snapshots associated with an automated backup. From there, you can restore a DB instance directly from one of those snapshots.

To describe the automated backups for your existing DB instances using the AWS CLI, use one of the following commands:

```
aws rds describe-db-instance-automated-backups --db-instance-  
identifier DBInstanceIdentifier
```

or

```
aws rds describe-db-instance-automated-backups --dbi-resource-id DbiResourceId
```

To describe the retained automated backups for your existing DB instances using the RDS API, call the [DescribeDBInstanceAutomatedBackups](#) action with one of the following parameters:

- `DBInstanceIdentifier`
- `DbiResourceId`

Retaining automated backups

When you delete a DB instance, you can retain automated backups.

Retained automated backups contain system snapshots and transaction logs from a DB instance. They also include your DB instance properties like allocated storage and DB instance class, which are required to restore it to an active instance.

You can retain automated backups for RDS instances running the MySQL, MariaDB, PostgreSQL, Oracle, and Microsoft SQL Server engines.

You can restore or remove retained automated backups using the AWS Management Console, RDS API, and AWS CLI.

Topics

- [Retention period \(p. 431\)](#)
- [Viewing retained backups \(p. 432\)](#)
- [Restoration \(p. 432\)](#)
- [Retention costs \(p. 432\)](#)
- [Limitations and recommendations \(p. 432\)](#)

Retention period

The system snapshots and transaction logs in a retained automated backup expire the same way that they expire for the source DB instance. Because there are no new snapshots or logs created for this

instance, the retained automated backups eventually expire completely. Effectively, they live as long their last system snapshot would have done, based on the settings for retention period the source instance had when you deleted it. Retained automated backups are removed by the system after their last system snapshot expires.

You can remove a retained automated backup in the same way that you can delete a DB instance. You can remove retained automated backups using the console or the RDS API operation `DeleteDBInstanceAutomatedBackup`.

Final snapshots are independent of retained automated backups. We strongly suggest that you take a final snapshot even if you retain automated backups, because the retained automated backups eventually expire. The final snapshot doesn't expire.

Viewing retained backups

To view your retained automated backups, choose **Automated backups** in the navigation pane, then choose **Retained**. To view individual snapshots associated with a retained automated backup, choose **Snapshots** in the navigation pane. Alternatively, you can describe individual snapshots associated with a retained automated backup. From there, you can restore a DB instance directly from one of those snapshots.

To describe your retained automated backups using the AWS CLI, use the following command:

```
aws rds describe-db-instance-automated-backups --dbi-resource-id DbiResourceId
```

To describe your retained automated backups using the RDS API, call the [DescribeDBInstanceAutomatedBackups](#) action with the `DbiResourceId` parameter.

Restoration

For information on restoring DB instances from automated backups, see [Restoring a DB instance to a specified time \(p. 499\)](#).

Retention costs

The cost of a retained automated backup is the cost of total storage of the system snapshots that are associated with it. There is no additional charge for transaction logs or instance metadata. All other pricing rules for backups apply to restorable instances.

For example, suppose that your total allocated storage of running instances is 100 GB. Suppose also that you have 50 GB of manual snapshots plus 75 GB of system snapshots associated with a retained automated backup. In this case, you are charged only for the additional 25 GB of backup storage, like this: $(50 \text{ GB} + 75 \text{ GB}) - 100 \text{ GB} = 25 \text{ GB}$.

Limitations and recommendations

The following limitations apply to retained automated backups:

- The maximum number of retained automated backups in one AWS Region is 40. It's not included in the DB instances limit. You can have 40 running DB instances and an additional 40 retained automated backups at the same time.
- Retained automated backups don't contain information about parameters or option groups.
- You can restore a deleted instance to a point in time that is within the retention period at the time of delete.

- You can't modify a retained automated backup. That's because it consists of system backups, transaction logs, and the DB instance properties that existed at the time that you deleted the source instance.

Deleting retained automated backups

You can delete retained automated backups when they are no longer needed.

Console

To delete a retained automated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Automated backups**.
3. On the **Retained** tab, choose the retained automated backup that you want to delete.
4. For **Actions**, choose **Delete**.
5. On the confirmation page, enter **delete me** and choose **Delete**.

AWS CLI

You can delete a retained automated backup by using the AWS CLI command `delete-db-instance-automated-backup` with the following option:

- `--dbi-resource-id` – The resource identifier for the source DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup by running the AWS CLI command `describe-db-instance-automated-backups`.

Example

The following example deletes the retained automated backup with source DB instance resource identifier db-123ABCEXAMPLE.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
--dbi-resource-id db-123ABCEXAMPLE
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
--dbi-resource-id db-123ABCEXAMPLE
```

RDS API

You can delete a retained automated backup by using the Amazon RDS API operation `DeleteDBInstanceAutomatedBackup` with the following parameter:

- `DbiResourceId` – The resource identifier for the source DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup using the Amazon RDS API operation `DescribeDBInstanceAutomatedBackups`.

Disabling automated backups

You might want to temporarily disable automated backups in certain situations, for example while loading large amounts of data.

Important

We highly discourage disabling automated backups because it disables point-in-time recovery. Disabling automatic backups for a DB instance deletes all existing automated backups for the instance. If you disable and then re-enable automated backups, you can restore starting only from the time you re-enabled automated backups.

Console

To disable automated backups immediately

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **Backup retention period**, choose **0 days**.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. On the confirmation page, choose **Modify DB instance** to save your changes and disable automated backups.

AWS CLI

To disable automated backups immediately, use the `modify-db-instance` command and set the backup retention period to 0 with `--apply-immediately`.

Example

The following example immediately disabled automatic backups.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --backup-retention-period 0 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --backup-retention-period 0 ^
  --apply-immediately
```

To know when the modification is in effect, call `describe-db-instances` for the DB instance until the value for backup retention period is 0 and `mydbinstance` status is available.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

RDS API

To disable automated backups immediately, call the [ModifyDBInstance](#) operation with the following parameters:

- DBInstanceIdentifier = mydbinstance
- BackupRetentionPeriod = 0

Example

```
https://rds.amazonaws.com/  
    ?Action=ModifyDBInstance  
    &DBInstanceIdentifier=mydbinstance  
    &BackupRetentionPeriod=0  
    &SignatureVersion=2  
    &SignatureMethod=HmacSHA256  
    &Timestamp=2009-10-14T17%3A48%3A21.746Z  
    &AWSAccessKeyId=<&AWS; Access Key ID>  
    &Signature=<Signature>
```

Using AWS Backup to manage automated backups

AWS Backup is a fully managed backup service that makes it easy to centralize and automate the backup of data across AWS services in the cloud and on premises. You can manage backups of your Amazon RDS DB instances in AWS Backup.

To enable backups in AWS Backup, you use resource tagging to associate your DB instance with a backup plan. For more information, see [Using tags to enable backups in AWS Backup \(p. 399\)](#).

Note

Backups managed by AWS Backup are considered manual DB snapshots, but don't count toward the DB snapshot quota for RDS. Backups that were created with AWS Backup have names ending in awsbackup:*backup-job-number*.

For more information about AWS Backup, see the [AWS Backup Developer Guide](#).

To view backups managed by AWS Backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Backup service** tab.

Your AWS Backup backups are listed under **Backup service snapshots**.

Automated backups with unsupported MySQL storage engines

For the MySQL DB engine, automated backups are only supported for the InnoDB storage engine. Use of these features with other MySQL storage engines, including MyISAM, can lead to unreliable behavior while restoring from backups. Specifically, since storage engines like MyISAM don't support reliable crash recovery, your tables can be corrupted in the event of a crash. For this reason, we encourage you to use the InnoDB storage engine.

- To convert existing MyISAM tables to InnoDB tables, you can use the ALTER TABLE command, for example: ALTER TABLE *table_name* ENGINE=innodb, ALGORITHM=COPY;
- If you choose to use MyISAM, you can attempt to manually repair tables that become damaged after a crash by using the REPAIR command. For more information, see [REPAIR TABLE statement](#) in the MySQL documentation. However, as noted in the MySQL documentation, there is a good chance that you might not be able to recover all your data.
- If you want to take a snapshot of your MyISAM tables before restoring, follow these steps:
 1. Stop all activity to your MyISAM tables (that is, close all sessions).

You can close all sessions by calling the `mysql.rds_kill` command for each process that is returned from the `SHOW FULL PROCESSLIST` command.

2. Lock and flush each of your MyISAM tables. For example, the following commands lock and flush two tables named `myisam_table1` and `myisam_table2`:

```
mysql> FLUSH TABLES myisam_table1, myisam_table2 WITH READ LOCK;
```

3. Create a snapshot of your DB instance. When the snapshot has completed, release the locks and resume activity on the MyISAM tables. You can release the locks on your tables using the following command:

```
mysql> UNLOCK TABLES;
```

These steps force MyISAM to flush data stored in memory to disk, which ensures a clean start when you restore from a DB snapshot. For more information on creating a DB snapshot, see [Creating a DB snapshot \(p. 448\)](#).

Automated backups with unsupported MariaDB storage engines

For the MariaDB DB engine, automated backups are only supported with the InnoDB storage engine. Use of these features with other MariaDB storage engines, including Aria, might lead to unreliable behavior while restoring from backups. Even though Aria is a crash-resistant alternative to MyISAM, your tables can still be corrupted in the event of a crash. For this reason, we encourage you to use the InnoDB storage engine.

- To convert existing Aria tables to InnoDB tables, you can use the ALTER TABLE command. For example: ALTER TABLE *table_name* ENGINE=innodb, ALGORITHM=COPY;
- If you choose to use Aria, you can attempt to manually repair tables that become damaged after a crash by using the REPAIR TABLE command. For more information, see <http://mariadb.com/kb/en/mariadb/repair-table/>.
- If you want to take a snapshot of your Aria tables before restoring, follow these steps:
 1. Stop all activity to your Aria tables (that is, close all sessions).
 2. Lock and flush each of your Aria tables.
 3. Create a snapshot of your DB instance. When the snapshot has completed, release the locks and resume activity on the Aria tables. These steps force Aria to flush data stored in memory to disk, thereby ensuring a clean start when you restore from a DB snapshot.

Replicating automated backups to another AWS Region

For added disaster recovery capability, you can configure your Amazon RDS database instance to replicate snapshots and transaction logs to a destination AWS Region of your choice. When backup replication is configured for a DB instance, RDS initiates a cross-Region copy of all snapshots and transaction logs as soon as they are ready on the DB instance.

DB snapshot copy charges apply to the data transfer. After the DB snapshot is copied, standard charges apply to storage in the destination Region. For more details, see [RDS Pricing](#).

For an example of using backup replication, see the AWS online tech talk [Managed Disaster Recovery with Amazon RDS for Oracle Cross-Region Automated Backups](#).

Topics

- [Source and destination AWS Region support \(p. 437\)](#)
- [Enabling cross-Region automated backups \(p. 439\)](#)
- [Finding information about replicated backups \(p. 441\)](#)
- [Restoring to a specified time from a replicated backup \(p. 444\)](#)
- [Stopping automated backup replication \(p. 445\)](#)
- [Deleting replicated backups \(p. 446\)](#)

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with cross-Region automated backups, see [Cross-Region automated backups \(p. 78\)](#).

Source and destination AWS Region support

Backup replication is supported between the following AWS Regions.

Source Region	Destination Regions available
Asia Pacific (Mumbai)	Asia Pacific (Singapore) US East (N. Virginia), US East (Ohio), US West (Oregon)
Asia Pacific (Osaka)	Asia Pacific (Tokyo)
Asia Pacific (Seoul)	Asia Pacific (Singapore), Asia Pacific (Tokyo) US East (N. Virginia), US East (Ohio), US West (Oregon)
Asia Pacific (Singapore)	Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Sydney), Asia Pacific (Tokyo) US East (N. Virginia), US East (Ohio), US West (Oregon)
Asia Pacific (Sydney)	Asia Pacific (Singapore) US East (N. Virginia), US West (N. California), US West (Oregon)

Source Region	Destination Regions available
Asia Pacific (Tokyo)	Asia Pacific (Osaka), Asia Pacific (Seoul), Asia Pacific (Singapore) US East (N. Virginia), US East (Ohio), US West (Oregon)
Canada (Central)	Europe (Ireland) US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon)
China (Beijing)	China (Ningxia)
China (Ningxia)	China (Beijing)
Europe (Frankfurt)	Europe (Ireland), Europe (London), Europe (Paris), Europe (Stockholm) US East (N. Virginia), US East (Ohio), US West (Oregon)
Europe (Ireland)	Canada (Central) Europe (Frankfurt), Europe (London), Europe (Paris), Europe (Stockholm) US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon)
Europe (London)	Europe (Frankfurt), Europe (Ireland), Europe (Paris), Europe (Stockholm) US East (N. Virginia)
Europe (Paris)	Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Stockholm) US East (N. Virginia)
Europe (Stockholm)	Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Paris) US East (N. Virginia)
South America (São Paulo)	US East (N. Virginia), US East (Ohio)
AWS GovCloud (US-East)	AWS GovCloud (US-West)
AWS GovCloud (US-West)	AWS GovCloud (US-East)
US East (N. Virginia)	Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo) Canada (Central) Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Paris), Europe (Stockholm) South America (São Paulo) US East (Ohio), US West (N. California), US West (Oregon)

Source Region	Destination Regions available
US East (Ohio)	Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Tokyo) Canada (Central) Europe (Frankfurt), Europe (Ireland) South America (São Paulo) US East (N. Virginia), US West (N. California), US West (Oregon)
US West (N. California)	Asia Pacific (Sydney) Canada (Central) Europe (Ireland) US East (N. Virginia), US East (Ohio), US West (Oregon)
US West (Oregon)	Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo) Canada (Central) Europe (Frankfurt), Europe (Ireland) US East (N. Virginia), US East (Ohio), US West (N. California)

You can also use the `describe-source-regions` AWS CLI command to find out which AWS Regions can replicate to each other. For more information, see [Finding information about replicated backups \(p. 441\)](#).

Enabling cross-Region automated backups

You can enable backup replication on new or existing DB instances using the Amazon RDS console. You can also use the `start-db-instance-automated-backups-replication` AWS CLI command or the `StartDBInstanceAutomatedBackupsReplication` RDS API operation. You can replicate up to 20 backups to each destination AWS Region for each AWS account.

Note

To be able to replicate automated backups, make sure to enable them. For more information, see [Enabling automated backups \(p. 429\)](#).

Console

You can enable backup replication for a new or existing DB instance:

- For a new DB instance, enable it when you launch the instance. For more information, see [Settings for DB instances \(p. 237\)](#).
- For an existing DB instance, use the following procedure.

To enable backup replication for an existing DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Automated backups**.
3. On the **Current Region** tab, choose the DB instance for which you want to enable backup replication.
4. For **Actions**, choose **Manage cross-Region replication**.
5. Under **Backup replication**, choose **Enable replication to another AWS Region**.
6. Choose the **Destination Region**.
7. Choose the **Replicated backup retention period**.
8. If you've enabled encryption on the source DB instance, choose the **AWS KMS key** for encrypting the backups.
9. Choose **Save**.

In the source Region, replicated backups are listed on the **Current Region** tab of the **Automated backups** page. In the destination Region, replicated backups are listed on the **Replicated backups** tab of the **Automated backups** page.

AWS CLI

Enable backup replication by using the [start-db-instance-automated-backups-replication](#) AWS CLI command.

The following CLI example replicates automated backups from a DB instance in the US West (Oregon) Region to the US East (N. Virginia) Region. It also encrypts the replicated backups, using an AWS KMS key in the destination Region.

To enable backup replication

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds start-db-instance-automated-backups-replication \
--region us-east-1 \
--source-db-instance-arn "arn:aws:rds:us-west-2:123456789012:db:mydatabase" \
--kms-key-id "arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE" \
--backup-retention-period 7
```

For Windows:

```
aws rds start-db-instance-automated-backups-replication ^
--region us-east-1 ^
--source-db-instance-arn "arn:aws:rds:us-west-2:123456789012:db:mydatabase" ^
--kms-key-id "arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE" ^
--backup-retention-period 7
```

The **--source-region** option is required when you encrypt backups between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. For **--source-region**, specify the AWS Region of the source DB instance.

If **--source-region** isn't specified, make sure to specify a **--pre-signed-url** value. A *presigned URL* is a URL that contains a Signature Version 4 signed request for the `start-db-instance-automated-backups-replication` command that is called in the source AWS Region. To learn more about the **pre-signed-url** option, see [start-db-instance-automated-backups-replication](#) in the [AWS CLI Command Reference](#).

RDS API

Enable backup replication by using the [StartDBInstanceAutomatedBackupsReplication](#) RDS API operation with the following parameters:

- Region
- SourceDBInstanceArn
- BackupRetentionPeriod
- KmsKeyId (optional)
- PreSignedUrl (required if you use KmsKeyId)

Note

If you encrypt the backups, you must also include a presigned URL. For more information on presigned URLs, see [Authenticating Requests: Using Query Parameters \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference* and [Signature Version 4 signing process](#) in the *AWS General Reference*.

Finding information about replicated backups

You can use the following CLI commands to find information about replicated backups:

- `describe-source-regions`
- `describe-db-instances`
- `describe-db-instance-automated-backups`

The following `describe-source-regions` example lists the source AWS Regions from which automated backups can be replicated to the US West (Oregon) destination Region.

To show information about source Regions

- Run the following command.

```
aws rds describe-source-regions --region us-west-2
```

The output shows that backups can be replicated from US East (N. Virginia), but not from US East (Ohio) or US West (N. California), into US West (Oregon).

```
{  
    "SourceRegions": [  
        ...  
        {  
            "RegionName": "us-east-1",  
            "Endpoint": "https://rds.us-east-1.amazonaws.com",  
            "Status": "available",  
            "SupportsDBInstanceAutomatedBackupsReplication": true  
        },  
        {  
            "RegionName": "us-east-2",  
            "Endpoint": "https://rds.us-east-2.amazonaws.com",  
            "Status": "available",  
            "SupportsDBInstanceAutomatedBackupsReplication": false  
        },  
        "RegionName": "us-west-1",  
        "Endpoint": "https://rds.us-west-1.amazonaws.com",  
        "Status": "available",  
        "SupportsDBInstanceAutomatedBackupsReplication": true  
    ]  
}
```

```
        "Status": "available",
        "SupportsDBInstanceAutomatedBackupsReplication": false
    ]
}
```

The following `describe-db-instances` example shows the automated backups for a DB instance.

To show the replicated backups for a DB instance

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
--db-instance-identifier mydatabase
```

For Windows:

```
aws rds describe-db-instances ^
--db-instance-identifier mydatabase
```

The output includes the replicated backups.

```
{
    "DBInstances": [
        {
            "StorageEncrypted": false,
            "Endpoint": {
                "HostedZoneId": "Z1PVIF0B656C1W",
                "Port": 1521,
                ...
                "BackupRetentionPeriod": 7,
                "DBInstanceAutomatedBackupsReplications": [{"DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7H0J4SIEEXAMPLE"}]
            }
        ]
    }
}
```

The following `describe-db-instance-automated-backups` example shows the automated backups for a DB instance.

To show automated backups for a DB instance

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds describe-db-instance-automated-backups \
--db-instance-identifier mydatabase
```

For Windows:

```
aws rds describe-db-instance-automated-backups ^
--db-instance-identifier mydatabase
```

The output shows the source DB instance and automated backups in US West (Oregon), with backups replicated to US East (N. Virginia).

```
{
    "DBInstanceAutomatedBackups": [
        {
            "DBInstanceArn": "arn:aws:rds:us-west-2:868710585169:db:mydatabase",
            "DbiResourceId": "db-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE",
            "DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-west-2:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE",
            "BackupRetentionPeriod": 7,
            "DBInstanceAutomatedBackupsReplications": [{"DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE"}]
            "Region": "us-west-2",
            "DBInstanceIdentifier": "mydatabase",
            "RestoreWindow": {
                "EarliestTime": "2020-10-26T01:09:07Z",
                "LatestTime": "2020-10-31T19:09:53Z",
            }
            ...
        }
    ]
}
```

The following `describe-db-instance-automated-backups` example uses the `--db-instance-automated-backups-arn` option to show the replicated backups in the destination Region.

To show replicated backups

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds describe-db-instance-automated-backups \
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE"
```

For Windows:

```
aws rds describe-db-instance-automated-backups ^
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE"
```

The output shows the source DB instance in US West (Oregon), with replicated backups in US East (N. Virginia).

```
{
    "DBInstanceAutomatedBackups": [
        {
            "DBInstanceArn": "arn:aws:rds:us-west-2:868710585169:db:mydatabase",
            "DbiResourceId": "db-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE",
            "DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE",
            "Region": "us-west-2",
            "DBInstanceIdentifier": "mydatabase",
            "RestoreWindow": {
                "EarliestTime": "2020-10-26T01:09:07Z",
                "LatestTime": "2020-10-31T19:01:23Z"
            },
        }
    ]
}
```

```
        "AllocatedStorage": 50,  
        "BackupRetentionPeriod": 7,  
        "Status": "replicating",  
        "Port": 1521,  
        ...  
    ]  
}
```

Restoring to a specified time from a replicated backup

You can restore a DB instance to a specific point in time from a replicated backup using the Amazon RDS console. You can also use the `restore-db-instance-to-point-in-time` AWS CLI command or the `RestoreDBInstanceToPointInTime` RDS API operation.

For general information on point-in-time recovery (PITR), see [Restoring a DB instance to a specified time \(p. 499\)](#).

Note

On RDS for SQL Server, option groups aren't copied across AWS Regions when automated backups are replicated. If you've associated a custom option group with your RDS for SQL Server DB instance, you can re-create that option group in the destination Region. Then restore the DB instance in the destination Region and associate the custom option group with it. For more information, see [Working with option groups \(p. 273\)](#).

Console

To restore a DB instance to a specified time from a replicated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the destination Region (where backups are replicated to) from the Region selector.
3. In the navigation pane, choose **Automated backups**.
4. On the **Replicated backups** tab, choose the DB instance that you want to restore.
5. For **Actions**, choose **Restore to point in time**.
6. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

If you chose **Custom**, enter the date and time that you want to restore the instance to.

Note

Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

7. For **DB instance identifier**, enter the name of the target restored DB instance.
8. (Optional) Choose other options as needed, such as enabling autoscaling.
9. Choose **Restore to point in time**.

AWS CLI

Use the `restore-db-instance-to-point-in-time` AWS CLI command to create a new DB instance.

To restore a DB instance to a specified time from a replicated backup

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
    --source-db-instance-automated-backups-arn "arn:aws:rds:us-
east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7H0J4SIEEXAMPLE" \
    --target-db-instance-identifier mytargetdbinstance \
    --restore-time 2020-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
    --source-db-instance-automated-backups-arn "arn:aws:rds:us-
east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7H0J4SIEEXAMPLE" ^
    --target-db-instance-identifier mytargetdbinstance ^
    --restore-time 2020-10-14T23:45:00.000Z
```

RDS API

To restore a DB instance to a specified time, call the [RestoreDBInstanceToPointInTime](#) Amazon RDS API operation with the following parameters:

- `SourceDBInstanceAutomatedBackupsArn`
- `TargetDBInstanceIdentifier`
- `RestoreTime`

Stopping automated backup replication

You can stop backup replication for DB instances using the Amazon RDS console. You can also use the `stop-db-instance-automated-backups-replication` AWS CLI command or the `StopDBInstanceAutomatedBackupsReplication` RDS API operation.

Replicated backups are retained, subject to the backup retention period set when they were created.

Console

Stop backup replication from the **Automated backups** page in the source Region.

To stop backup replication to an AWS Region

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the source Region from the **Region selector**.
3. In the navigation pane, choose **Automated backups**.
4. On the **Current Region** tab, choose the DB instance for which you want to stop backup replication.
5. For **Actions**, choose **Manage cross-Region replication**.
6. Under **Backup replication**, clear the **Enable replication to another AWS Region** check box.
7. Choose **Save**.

Replicated backups are listed on the **Retained** tab of the **Automated backups** page in the destination Region.

AWS CLI

Stop backup replication by using the [stop-db-instance-automated-backups-replication](#) AWS CLI command.

The following CLI example stops automated backups of a DB instance from replicating in the US West (Oregon) Region.

To stop backup replication

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds stop-db-instance-automated-backups-replication \
--region us-east-1 \
--source-db-instance-arn "arn:aws:rds:us-west-2:123456789012:db:mydatabase"
```

For Windows:

```
aws rds stop-db-instance-automated-backups-replication ^
--region us-east-1 ^
--source-db-instance-arn "arn:aws:rds:us-west-2:123456789012:db:mydatabase"
```

RDS API

Stop backup replication by using the [StopDBInstanceAutomatedBackupsReplication](#) RDS API operation with the following parameters:

- Region
- SourceDBInstanceArn

Deleting replicated backups

You can delete replicated backups for DB instances using the Amazon RDS console. You can also use the `delete-db-instance-automated-backups` AWS CLI command or the `DeleteDBInstanceAutomatedBackup` RDS API operation.

Console

Delete replicated backups in the destination Region from the **Automated backups** page.

To delete replicated backups

- Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
- Choose the destination Region from the **Region selector**.
- In the navigation pane, choose **Automated backups**.
- On the **Replicated backups** tab, choose the DB instance for which you want to delete the replicated backups.
- For **Actions**, choose **Delete**.
- On the confirmation page, enter **delete me** and choose **Delete**.

AWS CLI

Delete replicated backups by using the [delete-db-instance-automated-backup](#) AWS CLI command.

You can use the [describe-db-instances](#) CLI command to find the Amazon Resource Names (ARNs) of the replicated backups. For more information, see [Finding information about replicated backups \(p. 441\)](#).

To delete replicated backups

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-
L2IJCEXJP7XQ7H0J4SIEEXAMPLE"
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-
L2IJCEXJP7XQ7H0J4SIEEXAMPLE"
```

RDS API

Delete replicated backups by using the [DeleteDBInstanceAutomatedBackup](#) RDS API operation with the `DBInstanceAutomatedBackupsArn` parameter.

Creating a DB snapshot

Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. Creating this DB snapshot on a Single-AZ DB instance results in a brief I/O suspension that can last from a few seconds to a few minutes, depending on the size and class of your DB instance. For MariaDB, MySQL, Oracle, and PostgreSQL, I/O activity is not suspended on your primary during backup for Multi-AZ deployments, because the backup is taken from the standby. For SQL Server, I/O activity is suspended briefly during backup for Multi-AZ deployments.

When you create a DB snapshot, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. The amount of time it takes to create a snapshot varies with the size of your databases. Since the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects the amount of time it takes to create the snapshot.

Note

Your DB instance must be in the available state to take a DB snapshot.

For PostgreSQL DB instances, data in unlogged tables might not be restored from snapshots.

For more information, see [Best practices for working with PostgreSQL \(p. 224\)](#).

Unlike automated backups, manual snapshots aren't subject to the backup retention period. Snapshots don't expire.

For very long-term backups of MariaDB, MySQL, and PostgreSQL data, we recommend exporting snapshot data to Amazon S3. If the major version of your DB engine is no longer supported, you can't restore to that version from a snapshot. For more information, see [Exporting DB snapshot data to Amazon S3 \(p. 481\)](#).

You can create a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. In the list of DB instances, choose the DB instance for which you want to take a snapshot.
4. For **Actions**, choose **Take snapshot**.

The **Take DB snapshot** window appears.

5. Enter the name of the snapshot in the **Snapshot name** box.

RDS > Databases > Take snapshot

Take DB snapshot

Settings
To take a snapshot of this DB instance you must provide a name for the snapshot.

DB instance
The unique key that identifies a DB instance. This parameter isn't case-sensitive.

database-2

Snapshot name
The identifier for the DB snapshot.

Cancel **Take snapshot**

6. Choose **Take snapshot**.

The **Snapshots** page appears, with the new DB snapshot's status shown as *Creating*. After its status is *Available*, you can see its creation time.

AWS CLI

When you create a DB snapshot using the AWS CLI, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. You can do this by using the AWS CLI [create-db-snapshot](#) command with the following parameters:

- `--db-instance-identifier`
- `--db-snapshot-identifier`

In this example, you create a DB snapshot called `mydbsnapshot` for a DB instance called `mydbinstance`.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
  --db-instance-identifier mydbinstance \
  --db-snapshot-identifier mydbsnapshot
```

For Windows:

```
aws rds create-db-snapshot ^
  --db-instance-identifier mydbinstance ^
  --db-snapshot-identifier mydbsnapshot
```

RDS API

When you create a DB snapshot using the Amazon RDS API, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. You can do this by using the Amazon RDS API [CreateDBSnapshot](#) command with the following parameters:

- `DBInstanceIdentifier`
- `DBSnapshotIdentifier`

Creating a Multi-AZ DB cluster snapshot

When you create a Multi-AZ DB cluster snapshot, make sure to identify which Multi-AZ DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later.

You can create a Multi-AZ DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a DB cluster snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. In the list, choose the Multi-AZ DB cluster for which you want to take a snapshot.
4. For **Actions**, choose **Take snapshot**.

The **Take DB snapshot** window appears.

5. For **Snapshot name**, enter the name of the snapshot.
6. Choose **Take snapshot**.

The **Snapshots** page appears, with the new Multi-AZ DB cluster snapshot's status shown as **Creating**. After its status is **Available**, you can see its creation time.

AWS CLI

You can create a Multi-AZ DB cluster snapshot by using the AWS CLI `create-db-cluster-snapshot` command with the following options:

- `--db-cluster-identifier`
- `--db-cluster-snapshot-identifier`

In this example, you create a Multi-AZ DB cluster snapshot called `mymultiazdbclustersnapshot` for a DB cluster called `mymultiazdbcluster`.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-snapshot \
  --db-cluster-identifier mymultiazdbcluster \
  --db-cluster-snapshot-identifier mymultiazdbclustersnapshot
```

For Windows:

```
aws rds create-db-cluster-snapshot ^
  --db-cluster-identifier mymultiazdbcluster ^
  --db-cluster-snapshot-identifier mymultiazdbclustersnapshot
```

RDS API

You can create a Multi-AZ DB cluster snapshot by using the Amazon RDS API `CreateDBClusterSnapshot` operation with the following parameters:

- **DBClusterIdentifier**
- **DBClusterSnapshotIdentifier**

Restoring from a DB snapshot

Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. You can create a new DB instance by restoring from a DB snapshot. You provide the name of the DB snapshot to restore from, and then provide a name for the new DB instance that is created from the restore. You can't restore from a DB snapshot to an existing DB instance; a new DB instance is created when you restore.

You can use the restored DB instance as soon as its status is available. The DB instance continues to load data in the background. This is known as *lazy loading*.

If you access data that hasn't been loaded yet, the DB instance immediately downloads the requested data from Amazon S3, and then continues loading the rest of the data in the background. For more information, see [Amazon EBS snapshots](#).

To help mitigate the effects of lazy loading on tables to which you require quick access, you can perform operations that involve full-table scans, such as `SELECT *`. This allows Amazon RDS to download all of the backed-up table data from S3.

You can restore a DB instance and use a different storage type than the source DB snapshot. In this case, the restoration process is slower because of the additional work required to migrate the data to the new storage type. If you restore to or from magnetic storage, the migration process is the slowest. That's because magnetic storage doesn't have the IOPS capability of Provisioned IOPS or General Purpose (SSD) storage.

You can use AWS CloudFormation to restore a DB instance from a DB instance snapshot. For more information, see [AWS::RDS::DBInstance](#) in the *AWS CloudFormation User Guide*.

Note

You can't restore a DB instance from a DB snapshot that is both shared and encrypted. Instead, you can make a copy of the DB snapshot and restore the DB instance from the copy. For more information, see [Copying a DB snapshot \(p. 458\)](#).

Parameter group considerations

We recommend that you retain the DB parameter group for any DB snapshots you create, so that you can associate your restored DB instance with the correct parameter group.

The default DB parameter group is associated with the restored instance, unless you choose a different one. No custom parameter settings are available in the default parameter group.

You can specify the parameter group when you restore the DB instance.

For more information about DB parameter groups, see [Working with parameter groups \(p. 289\)](#).

Security group considerations

When you restore a DB instance, the default virtual private cloud (VPC), DB subnet group, and VPC security group are associated with the restored instance, unless you choose different ones.

- If you're using the Amazon RDS console, you can specify a custom VPC security group to associate with the instance or create a new VPC security group.
- If you're using the AWS CLI, you can specify a custom VPC security group to associate with the instance by including the `--vpc-security-group-ids` option in the `restore-db-instance-from-db-snapshot` command.

- If you're using the Amazon RDS API, you can include the `VpcSecurityGroupIds.VpcSecurityGroupId.N` parameter in the `RestoreDBInstanceFromDBSnapshot` action.

As soon as the restore is complete and your new DB instance is available, you can also change the VPC settings by modifying the DB instance. For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

Option group considerations

When you restore a DB instance, the default DB option group is associated with the restored DB instance in most cases.

The exception is when the source DB instance is associated with an option group that contains a persistent or permanent option. For example, if the source DB instance uses Oracle Transparent Data Encryption (TDE), the restored DB instance must use an option group that has the TDE option.

If you restore a DB instance into a different VPC, you must do one of the following to assign a DB option group:

- Assign the default option group for that VPC group to the instance.
- Assign another option group that is linked to that VPC.
- Create a new option group and assign it to the DB instance. With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option.

For more information about DB option groups, see [Working with option groups \(p. 273\)](#).

Resource tagging considerations

When you restore a DB instance from a DB snapshot, RDS checks whether you specify new tags. If yes, the new tags are added to the restored DB instance. If there are no new tags, RDS looks for the tags from the source DB instance for the DB snapshot, and then adds those tags to the restored DB instance.

For more information, see [Copying tags to DB instance snapshots \(p. 396\)](#).

Microsoft SQL Server considerations

When you restore an RDS for Microsoft SQL Server DB snapshot to a new instance, you can always restore to the same edition as your snapshot. In some cases, you can also change the edition of the DB instance. The following limitations apply when you change editions:

- The DB snapshot must have enough storage allocated for the new edition.
- Only the following edition changes are supported:
 - From Standard Edition to Enterprise Edition
 - From Web Edition to Standard Edition or Enterprise Edition
 - From Express Edition to Web Edition, Standard Edition, or Enterprise Edition

If you want to change from one edition to a new edition that isn't supported by restoring a snapshot, you can try using the native backup and restore feature. SQL Server verifies whether your database is compatible with the new edition based on what SQL Server features you have enabled on the database. For more information, see [Importing and exporting SQL Server databases using native backup and restore \(p. 1099\)](#).

Oracle Database considerations

If you use Oracle GoldenGate, always retain the parameter group with the compatible parameter. When you restore a DB instance from a DB snapshot, specify a parameter group that has a matching or greater compatible value.

If you restore a snapshot of a CDB instance, you can change the PDB name. You can't change the CDB name, which is always RDSCDB. This CDB name is the same for all RDS instances that use a single-tenant architecture. For more information, see [Snapshots in a single-tenant architecture \(p. 1482\)](#).

Before you restore a DB snapshot, you can upgrade it to a later release. For more information, see [Upgrading an Oracle DB snapshot \(p. 1764\)](#).

Restoring from a snapshot

You can restore a DB instance from a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore a DB instancefrom a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore snapshot** page, for **DB instance identifier**, enter the name for your restored DB instance.
6. Specify other settings.

For information about each setting, see [Settings for DB instances \(p. 237\)](#).

7. Choose **Restore DB instance**.

AWS CLI

To restore a DB instance from a DB snapshot, use the AWS CLI command `restore-db-instance-from-db-snapshot`.

In this example, you restore from a previously created DB snapshot named `mydbsnapshot`. You restore to a new DB instance named `mynewdbinstance`.

You can specify other settings. For information about each setting, see [Settings for DB instances \(p. 237\)](#).

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
--db-instance-identifier mynewdbinstance \
--db-snapshot-identifier mydbsnapshot
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
--db-instance-identifier mynewdbinstance ^
--db-snapshot-identifier mydbsnapshot
```

This command returns output similar to the following:

```
DBINSTANCE mynewdbinstance db.t3.small MySQL 50 sa creating 3 n
8.0.28 general-public-license
```

RDS API

To restore a DB instance from a DB snapshot, call the Amazon RDS API function [RestoreDBInstanceFromDBSnapshot](#) with the following parameters:

- **DBInstanceIdentifier**
- **DBSnapshotIdentifier**

Restoring from a snapshot to a Multi-AZ DB cluster

You can restore a snapshot to a Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API. You can restore each of these types of snapshots to a Multi-AZ DB cluster:

- A snapshot of a single-AZ deployment
- A snapshot of a Multi-AZ DB instance deployment with a single DB instance
- A snapshot of a Multi-AZ DB cluster

Tip

You can migrate a single-AZ deployment or a Multi-AZ DB instance deployment to a Multi-AZ DB cluster deployment by restoring a snapshot.

Console

To restore a snapshot to a Multi-AZ DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore snapshot** page, in **Availability and durability**, choose **Multi-AZ DB cluster**.

Availability and durability

Deployment options [Info](#)

The deployment options below are limited to those supported by the engine you selected above.

Multi-AZ DB cluster
Creates a DB cluster with a primary DB instance and two readable standby DB instances, with each DB instance in a different Availability Zone (AZ). Provides high availability, data redundancy and increases capacity to serve read workloads.

Multi-AZ DB instance
Creates a primary DB instance and a standby DB instance in a different AZ. Provides high availability and data redundancy, but the standby DB instance doesn't support connections for read workloads.

Single DB instance
Creates a single DB instance with no standby DB instances.

6. In **DB instance class**, choose a DB instance class.
Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see [DB instance classes \(p. 10\)](#).
7. For **DB cluster identifier**, enter the name for your restored Multi-AZ DB cluster.
8. For the remaining sections, specify your DB cluster settings. For information about each setting, see [Settings for creating Multi-AZ DB clusters \(p. 258\)](#).
9. Choose **Restore DB cluster**.

AWS CLI

To restore a snapshot to a Multi-AZ DB cluster, use the AWS CLI command [restore-db-cluster-from-snapshot](#).

In the following example, you restore from a previously created snapshot named `mysnapshot`. You restore to a new Multi-AZ DB cluster named `mynewmultiazdbcluster`. You also specify the DB instance class used by the DB instances in the Multi-AZ DB cluster. Specify either `mysql` or `postgres` for the DB engine.

For the `--snapshot-identifier` option, you can use either the name or the Amazon Resource Name (ARN) to specify a DB cluster snapshot. However, you can use only the ARN to specify a DB snapshot.

Currently, Multi-AZ DB clusters only support `db.m6gd` and `db.r6gd` DB instance classes. For more information about DB instance classes, see [DB instance classes \(p. 10\)](#).

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \
--db-cluster-identifier mynewmultiazdbcluster \
--snapshot-identifier mysnapshot \
--engine mysql|postgres \
--db-cluster-instance-class db.r6gd.xlarge
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
--db-cluster-identifier mynewmultiazdbcluster ^
--snapshot-identifier mysnapshot ^
--engine mysql|postgres ^
--db-cluster-instance-class db.r6gd.xlarge
```

After the DB cluster has been restored, make sure to add the Multi-AZ DB cluster to the security group used by the DB cluster or DB instance used to create the snapshot. Doing so provides the same functionality as that of the previous DB cluster or DB instance.

RDS API

To restore a snapshot to a Multi-AZ DB cluster, call the RDS API operation [RestoreDBClusterFromSnapshot](#) with the following parameters:

- `DBClusterIdentifier`
- `SnapshotIdentifier`
- `Engine`

You can also specify other optional parameters.

After the DB cluster has been restored, make sure to add the Multi-AZ DB cluster to the security group used by the DB cluster or DB instance used to create the snapshot. Doing so provides the same functionality as that of the previous DB cluster or DB instance.

Copying a DB snapshot

With Amazon RDS, you can copy automated backups or manual DB snapshots. After you copy a snapshot, the copy is a manual snapshot. You can make multiple copies of an automated backup or manual snapshot, but each copy must have a unique identifier.

You can copy a snapshot within the same AWS Region, you can copy a snapshot across AWS Regions, and you can copy shared snapshots.

Limitations

The following are some limitations when you copy snapshots:

- You can't copy a snapshot to or from the China (Beijing) Region or the China (Ningxia) Region.
- You can copy a snapshot between AWS GovCloud (US-East) and AWS GovCloud (US-West). However, you can't copy a snapshot between these GovCloud (US) Regions and Regions that aren't GovCloud (US) Regions.
- If you delete a source snapshot before the target snapshot becomes available, the snapshot copy might fail. Verify that the target snapshot has a status of AVAILABLE before you delete a source snapshot.
- You can have up to 20 snapshot copy requests in progress to a single destination Region per account.
- When you request multiple snapshot copies for the same source DB instance, they're queued internally. The copies requested later won't start until the previous snapshot copies are completed. For more information, see [Why is my EC2 AMI or EBS snapshot creation slow?](#) in the AWS Knowledge Center.
- Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete. In some cases, there might be a large number of cross-Region snapshot copy requests from a given source Region. In such cases, Amazon RDS might put new cross-Region copy requests from that source Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copy starts.

Snapshot retention

Amazon RDS deletes automated backups in several situations:

- At the end of their retention period.
- When you disable automated backups for a DB instance.
- When you delete a DB instance.

If you want to keep an automated backup for a longer period, copy it to create a manual snapshot, which is retained until you delete it. Amazon RDS storage costs might apply to manual snapshots if they exceed your default storage space.

For more information about backup storage costs, see [Amazon RDS pricing](#).

Copying shared snapshots

You can copy snapshots shared to you by other AWS accounts. In some cases, you might copy an encrypted snapshot that has been shared from another AWS account. In these cases, you must have access to the AWS KMS key that was used to encrypt the snapshot.

You can copy a shared DB snapshot across AWS Regions if the snapshot is unencrypted. However, if the shared DB snapshot is encrypted, you can only copy it in the same Region.

Note

Copying shared incremental snapshots in the same AWS Region is supported when they're unencrypted, or encrypted using the same KMS key as the initial full snapshot. If you use a different KMS key to encrypt subsequent snapshots when copying them, those shared snapshots are full snapshots. For more information, see [Incremental snapshot copying \(p. 459\)](#).

Handling encryption

You can copy a snapshot that has been encrypted using a KMS key. If you copy an encrypted snapshot, the copy of the snapshot must also be encrypted. If you copy an encrypted snapshot within the same AWS Region, you can encrypt the copy with the same KMS key as the original snapshot. Or you can specify a different KMS key.

If you copy an encrypted snapshot across Regions, you must specify a KMS key valid in the destination AWS Region. It can be a Region-specific KMS key, or a multi-Region key. For more information on multi-Region KMS keys, see [Using multi-Region keys in AWS KMS](#).

The source snapshot remains encrypted throughout the copy process. For more information, see [Limitations of Amazon RDS encrypted DB instances \(p. 2003\)](#).

You can also encrypt a copy of an unencrypted snapshot. This way, you can quickly add encryption to a previously unencrypted DB instance. To do this, you create a snapshot of your DB instance when you are ready to encrypt it. You then create a copy of that snapshot and specify a KMS key to encrypt that snapshot copy. You can then restore an encrypted DB instance from the encrypted snapshot.

Incremental snapshot copying

An *incremental* snapshot contains only the data that has changed after the most recent snapshot of the same DB instance. Incremental snapshot copying is faster and results in lower storage costs than full snapshot copying.

Note

When you copy a source snapshot that is a snapshot copy itself, the new copy isn't incremental. This is because the source snapshot copy doesn't include the required metadata for incremental copies.

Whether a snapshot copy is incremental is determined by the most recently completed snapshot copy. If the most recent snapshot copy was deleted, the next copy is a full copy, not an incremental copy.

If a copy is still pending when you start another copy, the second copy doesn't start until the first copy finishes.

When you copy a snapshot across AWS accounts, the copy is an incremental copy if the following conditions are met:

- A different snapshot of the same source DB instance was previously copied to the destination account.
- The most recent snapshot copy still exists in the destination account.
- All copies of the snapshot in the destination account are either unencrypted, or were encrypted using the same KMS key.

The following examples illustrate the difference between full and incremental snapshots. They apply to both shared and unshared snapshots.

Snapshot	Encryption key	Full or incremental
S1	K1	Full

Snapshot	Encryption key	Full or incremental
S2	K1	Incremental of S1
S3	K1	Incremental of S2
S4	K1	Incremental of S3
Copy of S1 (S1C)	K2	Full
Copy of S2 (S2C)	K3	Full
Copy of S3 (S3C)	K3	Incremental of S2C
Copy of S4 (S4C)	K3	Incremental of S3C
Copy 2 of S4 (S4C2)	K4	Full

Note

In these examples, snapshots S2, S3, and S4 are incremental only if the previous snapshot still exists.

The same applies to copies. Snapshot copies S3C and S4C are incremental only if the previous copy still exists.

For information on copying incremental snapshots across AWS Regions, see [Full and incremental copies \(p. 463\)](#).

Cross-Region snapshot copying

You can copy DB snapshots across AWS Regions. However, there are certain constraints and considerations for cross-Region snapshot copying.

Requesting a cross-Region DB snapshot copy

To communicate with the source Region to request a cross-Region DB snapshot copy, the requester (IAM role or IAM user) must have access to the source DB snapshot and the source Region.

Certain conditions in the requester's IAM policy can cause the request to fail. The following examples assume that you're copying the DB snapshot from US East (Ohio) to US East (N. Virginia). These examples show conditions in the requester's IAM policy that cause the request to fail:

- The requester's policy has a condition for `aws:RequestedRegion`.

```

...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:RequestedRegion": "us-east-1"
    }
}
}
```

The request fails because the policy doesn't allow access to the source Region. For a successful request, specify both the source and destination Regions.

```

...
"Effect": "Allow",
```

```
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:RequestedRegion": [
            "us-east-1",
            "us-east-2"
        ]
    }
}
```

- The requester's policy doesn't allow access to the source DB snapshot.

```
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "arn:aws:rds:us-east-1:123456789012:snapshot:target-snapshot"
...
```

For a successful request, specify both the source and target snapshots.

```
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": [
    "arn:aws:rds:us-east-1:123456789012:snapshot:target-snapshot",
    "arn:aws:rds:us-east-2:123456789012:snapshot:source-snapshot"
]
...
```

- The requester's policy denies aws:ViaAWSService.

```
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
"Condition": {
    "Bool": {"aws:ViaAWSService": "false"}
}
```

Communication with the source Region is made by RDS on the requester's behalf. For a successful request, don't deny calls made by AWS services.

- The requester's policy has a condition for aws:SourceVpc or aws:SourceVpce.

These requests might fail because when RDS makes the call to the remote Region, it isn't from the specified VPC or VPC endpoint.

If you need to use one of the previous conditions that would cause a request to fail, you can include a second statement with aws:CalledVia in your policy to make the request succeed. For example, you can use aws:CalledVia with aws:SourceVpce as shown here:

```
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
"Condition": {
    "Condition" : {
        "ForAnyValue:StringEquals" : {
            "aws:SourceVpce": "vpce-1a2b3c4d"
        }
    }
}
```

```
        },
    },
{
    "Effect": "Allow",
    "Action": [
        "rds:CopyDBSnapshot"
    ],
    "Resource": "*",
    "Condition": {
        "ForAnyValue:StringEquals": {
            "aws:CalledVia": [
                "rds.amazonaws.com"
            ]
        }
    }
}
```

For more information, see [Policies and permissions in IAM](#) in the *IAM User Guide*.

Authorizing the snapshot copy

After a cross-Region DB snapshot copy request returns success, RDS starts the copy in the background. An authorization for RDS to access the source snapshot is created. This authorization links the source DB snapshot to the target DB snapshot, and allows RDS to copy only to the specified target snapshot.

The authorization is verified by RDS using the `rds:CrossRegionCommunication` permission in the service-linked IAM role. If the copy is authorized, RDS communicates with the source Region and completes the copy.

RDS doesn't have access to DB snapshots that weren't authorized previously by a `CopyDBSnapshot` request. The authorization is revoked when copying completes.

RDS uses the service-linked role to verify the authorization in the source Region. If you delete the service-linked role during the copy process, the copy fails.

For more information, see [Using service-linked roles](#) in the *IAM User Guide*.

Using AWS Security Token Service credentials

Session tokens from the global AWS Security Token Service (AWS STS) endpoint are valid only in AWS Regions that are enabled by default (commercial Regions). If you use credentials from the `assumeRole` API operation in AWS STS, use the regional endpoint if the source Region is an opt-in Region. Otherwise, the request fails. This happens because your credentials must be valid in both Regions, which is true for opt-in Regions only when the regional AWS STS endpoint is used.

To use the global endpoint, make sure that it's enabled for both Regions in the operations. Set the global endpoint to `Valid in all AWS Regions` in the AWS STS account settings.

The same rule applies to credentials in the `presigned URL` parameter.

For more information, see [Managing AWS STS in an AWS Region](#) in the *IAM User Guide*.

Latency and multiple copy requests

Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete.

In some cases, there might be a large number of cross-Region snapshot copy requests from a given source AWS Region. In such cases, Amazon RDS might put new cross-Region copy requests from that

source AWS Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copying starts.

Full and incremental copies

When you copy a snapshot to a different AWS Region from the source snapshot, the first copy is a full snapshot copy, even if you copy an incremental snapshot. A full snapshot copy contains all of the data and metadata required to restore the DB instance. After the first snapshot copy, you can copy incremental snapshots of the same DB instance to the same destination Region within the same AWS account. For more information on incremental snapshots, see [Incremental snapshot copying \(p. 459\)](#).

Incremental snapshot copying across AWS Regions is supported for both unencrypted and encrypted snapshots.

When you copy a snapshot across AWS Regions, the copy is an incremental copy if the following conditions are met:

- The snapshot was previously copied to the destination Region.
- The most recent snapshot copy still exists in the destination Region.
- All copies of the snapshot in the destination Region are either unencrypted, or were encrypted using the same KMS key.

Option group considerations

Option groups are specific to the AWS Region that they are created in, and you can't use an option group from one AWS Region in another AWS Region.

When you copy a snapshot across Regions, you can specify a new option group for the snapshot. We recommend that you prepare the new option group before you copy the snapshot. In the destination AWS Region, create an option group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.

In some cases, you might copy a snapshot and not specify a new option group for the snapshot. In these cases, when you restore the snapshot the DB instance gets the default option group. To give the new DB instance the same options as the original, do the following:

1. In the destination AWS Region, create an option group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.
2. After you restore the snapshot in the destination AWS Region, modify the new DB instance and add the new or existing option group from the previous step.

Parameter group considerations

When you copy a snapshot across Regions, the copy doesn't include the parameter group used by the original DB instance. When you restore a snapshot to create a new DB instance, that DB instance gets the default parameter group for the AWS Region it is created in. To give the new DB instance the same parameters as the original, do the following:

1. In the destination AWS Region, create a DB parameter group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.
2. After you restore the snapshot in the destination AWS Region, modify the new DB instance and add the new or existing parameter group from the previous step.

Copying a DB snapshot

Use the procedures in this topic to copy a DB snapshot. For an overview of copying a snapshot, see [Copying a DB snapshot \(p. 458\)](#)

For each AWS account, you can copy up to five DB snapshots at a time from one AWS Region to another. If you copy a DB snapshot to another AWS Region, you create a manual DB snapshot that is retained in that AWS Region. Copying a DB snapshot out of the source AWS Region incurs Amazon RDS data transfer charges.

For more information about data transfer pricing, see [Amazon RDS pricing](#).

After the DB snapshot copy has been created in the new AWS Region, the DB snapshot copy behaves the same as all other DB snapshots in that AWS Region.

You can copy a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

The following procedure copies an encrypted or unencrypted DB snapshot, in the same AWS Region or across Regions, by using the AWS Management Console.

To copy a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the DB snapshot that you want to copy.
4. For **Actions**, choose **Copy snapshot**.

The **Copy snapshot** page appears.

RDS > Snapshots > Copy snapshot

Copy snapshot

Settings

Source DB Snapshot
DB Snapshot Identifier for the snapshot being copied.
db1-snapshot

Destination Region [Info](#)
US West (Oregon)

New DB Snapshot Identifier
DB Snapshot Identifier for the new snapshot

Target Option Group (Optional)
No preference

Copy Tags [Info](#)

i Please note that depending on the amount of data to be copied and the Region you choose, this operation could take several hours to complete and the display on the progress bar could be delayed until setup is complete.

Encryption

Encryption [Info](#)
 Enable Encryption
Choose to encrypt the copy of the source DB snapshot. Master key IDs and aliases appear in the list after they have been created using KMS. You cannot remove encryption from an encrypted DB snapshot.

Master key [Info](#)
(default) aws/rds

Account

KMS key ID

Cancel **Copy snapshot**

5. (Optional) To copy the DB snapshot to a different AWS Region, for **Destination Region**, choose the new AWS Region.

Note

The destination AWS Region must have the same database engine version available as the source AWS Region.

6. For **New DB Snapshot Identifier**, type the name of the DB snapshot copy.

You can make multiple copies of an automated backup or manual snapshot, but each copy must have a unique identifier.

7. (Optional) For **Target Option Group**, choose a new option group.

Specify this option if you are copying a snapshot from one AWS Region to another, and your DB instance uses a nondefault option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this option when copying across Regions. For more information, see [Option group considerations \(p. 463\)](#).

8. (Optional) Select **Copy Tags** to copy tags and values from the snapshot to the copy of the snapshot.
9. (Optional) For **Encryption**, do the following:

- a. Choose **Enable Encryption** if the DB snapshot isn't encrypted but you want to encrypt the copy.

Note

If the DB snapshot is encrypted, you must encrypt the copy, so the check box is already selected.

- b. For **AWS KMS key**, specify the KMS key identifier to use to encrypt the DB snapshot copy.

10. Choose **Copy snapshot**.

AWS CLI

You can copy a DB snapshot by using the AWS CLI command `copy-db-snapshot`. If you are copying the snapshot to a new AWS Region, run the command in the new AWS Region.

The following options are used to copy a DB snapshot. Not all options are required for all scenarios. Use the descriptions and the examples that follow to determine which options to use.

- `--source-db-snapshot-identifier` – The identifier for the source DB snapshot.
 - If the source snapshot is in the same AWS Region as the copy, specify a valid DB snapshot identifier. For example, `rds:mysql-instance1-snapshot-20130805`.
 - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
 - If you are copying from a shared manual DB snapshot, this parameter must be the Amazon Resource Name (ARN) of the shared DB snapshot.
 - If you are copying an encrypted snapshot this parameter must be in the ARN format for the source AWS Region, and must match the `SourceDBSnapshotIdentifier` in the `PreSignedUrl` parameter.
- `--target-db-snapshot-identifier` – The identifier for the new copy of the encrypted DB snapshot.
- `--copy-tags` – Include the `copy tags` option to copy tags and values from the snapshot to the copy of the snapshot.
- `--option-group-name` – The option group to associate with the copy of the snapshot.

Specify this option if you are copying a snapshot from one AWS Region to another, and your DB instance uses a non-default option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this option when copying across Regions. For more information, see [Option group considerations \(p. 463\)](#).

- `--kms-key-id` – The KMS key identifier for an encrypted DB snapshot. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key.
 - If you copy an encrypted DB snapshot from your AWS account, you can specify a value for this parameter to encrypt the copy with a new KMS key. If you don't specify a value for this parameter, then the copy of the DB snapshot is encrypted with the same KMS key as the source DB snapshot.
 - If you copy an encrypted DB snapshot that is shared from another AWS account, then you must specify a value for this parameter.
 - If you specify this parameter when you copy an unencrypted snapshot, the copy is encrypted.
 - If you copy an encrypted snapshot to a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS keys are specific to the AWS Region that they are created in, and you cannot use encryption keys from one AWS Region in another AWS Region.

Example from unencrypted, to the same Region

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the same AWS Region as the source snapshot. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot \
  --source-db-snapshot-identifier mysql-instance1-snapshot-20130805 \
  --target-db-snapshot-identifier mydbsnapshotcopy \
  --copy-tags
```

For Windows:

```
aws rds copy-db-snapshot ^
  --source-db-snapshot-identifier mysql-instance1-snapshot-20130805 ^
  --target-db-snapshot-identifier mydbsnapshotcopy ^
  --copy-tags
```

Example from unencrypted, across Regions

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the AWS Region in which the command is run.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot \
  --source-db-snapshot-identifier arn:aws:rds:us-east-1:123456789012:snapshot:mysql-
instance1-snapshot-20130805 \
  --target-db-snapshot-identifier mydbsnapshotcopy
```

For Windows:

```
aws rds copy-db-snapshot ^
  --source-db-snapshot-identifier arn:aws:rds:us-east-1:123456789012:snapshot:mysql-
instance1-snapshot-20130805 ^
  --target-db-snapshot-identifier mydbsnapshotcopy
```

Example from encrypted, across Regions

The following code example copies an encrypted DB snapshot from the US West (Oregon) Region in the US East (N. Virginia) Region. Run the command in the destination (us-east-1) Region.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot \
--source-db-snapshot-identifier arn:aws:rds:us-west-2:123456789012:snapshot:mysql-
instance1-snapshot-20161115 \
--target-db-snapshot-identifier mydbsnapshotcopy \
--kms-key-id my-us-east-1-key \
--option-group-name custom-option-group-name
```

For Windows:

```
aws rds copy-db-snapshot ^
--source-db-snapshot-identifier arn:aws:rds:us-west-2:123456789012:snapshot:mysql-
instance1-snapshot-20161115 ^
--target-db-snapshot-identifier mydbsnapshotcopy ^
--kms-key-id my-us-east-1-key ^
--option-group-name custom-option-group-name
```

The `--source-region` parameter is required when you're copying an encrypted snapshot between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. For `--source-region`, specify the AWS Region of the source DB instance.

If `--source-region` isn't specified, specify a `--pre-signed-url` value. A *presigned URL* is a URL that contains a Signature Version 4 signed request for the `copy-db-snapshot` command that's called in the source AWS Region. To learn more about the `pre-signed-url` option, see [copy-db-snapshot](#) in the [AWS CLI Command Reference](#).

RDS API

You can copy a DB snapshot by using the Amazon RDS API operation [CopyDBSnapshot](#). If you are copying the snapshot to a new AWS Region, perform the action in the new AWS Region.

The following parameters are used to copy a DB snapshot. Not all parameters are required for all scenarios. Use the descriptions and the examples that follow to determine which parameters to use.

- `SourceDBSnapshotIdentifier` – The identifier for the source DB snapshot.
 - If the source snapshot is in the same AWS Region as the copy, specify a valid DB snapshot identifier. For example, `rds:mysql-instance1-snapshot-20130805`.
 - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
 - If you are copying from a shared manual DB snapshot, this parameter must be the Amazon Resource Name (ARN) of the shared DB snapshot.
 - If you are copying an encrypted snapshot this parameter must be in the ARN format for the source AWS Region, and must match the `SourceDBSnapshotIdentifier` in the `PreSignedUrl` parameter.
- `TargetDBSnapshotIdentifier` – The identifier for the new copy of the encrypted DB snapshot.
- `CopyTags` – Set this parameter to `true` to copy tags and values from the snapshot to the copy of the snapshot. The default is `false`.
- `OptionGroupName` – The option group to associate with the copy of the snapshot.

Specify this parameter if you are copying a snapshot from one AWS Region to another, and your DB instance uses a non-default option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this parameter when copying across Regions. For more information, see [Option group considerations \(p. 463\)](#).

- **KmsKeyId** – The KMS key identifier for an encrypted DB snapshot. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key.
 - If you copy an encrypted DB snapshot from your AWS account, you can specify a value for this parameter to encrypt the copy with a new KMS key. If you don't specify a value for this parameter, then the copy of the DB snapshot is encrypted with the same KMS key as the source DB snapshot.
 - If you copy an encrypted DB snapshot that is shared from another AWS account, then you must specify a value for this parameter.
 - If you specify this parameter when you copy an unencrypted snapshot, the copy is encrypted.
 - If you copy an encrypted snapshot to a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS keys are specific to the AWS Region that they are created in, and you cannot use encryption keys from one AWS Region in another AWS Region.
- **PreSignedUrl** – The URL that contains a Signature Version 4 signed request for the `CopyDBSnapshot` API operation in the source AWS Region that contains the source DB snapshot to copy.

Specify this parameter when you copy an encrypted DB snapshot from another AWS Region by using the Amazon RDS API. You can specify the source Region option instead of this parameter when you copy an encrypted DB snapshot from another AWS Region by using the AWS CLI.

The presigned URL must be a valid request for the `CopyDBSnapshot` API operation that can be run in the source AWS Region containing the encrypted DB snapshot to be copied. The presigned URL request must contain the following parameter values:

- **DestinationRegion** – The AWS Region that the encrypted DB snapshot will be copied to. This AWS Region is the same one where the `CopyDBSnapshot` operation is called that contains this presigned URL.

For example, suppose that you copy an encrypted DB snapshot from the us-west-2 Region to the us-east-1 Region. You then call the `CopyDBSnapshot` operation in the us-east-1 Region and provide a presigned URL that contains a call to the `CopyDBSnapshot` operation in the us-west-2 Region. For this example, the **DestinationRegion** in the presigned URL must be set to the us-east-1 Region.

- **KmsKeyId** – The KMS key identifier for the key to use to encrypt the copy of the DB snapshot in the destination AWS Region. This is the same identifier for both the `CopyDBSnapshot` operation that is called in the destination AWS Region, and the operation contained in the presigned URL.
- **SourceDBSnapshotIdentifier** – The DB snapshot identifier for the encrypted snapshot to be copied. This identifier must be in the Amazon Resource Name (ARN) format for the source AWS Region. For example, if you are copying an encrypted DB snapshot from the us-west-2 Region, then your **SourceDBSnapshotIdentifier** looks like the following example: `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20161115`.

For more information on Signature Version 4 signed requests, see the following:

- [Authenticating requests: Using query parameters \(AWS signature version 4\)](#) in the Amazon Simple Storage Service API Reference
- [Signature version 4 signing process](#) in the AWS General Reference

Example from unencrypted, to the same Region

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the same AWS Region as the source snapshot. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.

```
https://rds.us-west-1.amazonaws.com/  
?Action=CopyDBSnapshot  
&CopyTags=true  
&SignatureMethod=HmacSHA256  
&SignatureVersion=4  
&SourceDBSnapshotIdentifier=mysql-instance1-snapshot-20130805  
&TargetDBSnapshotIdentifier=mydbsnapshotcopy  
&Version=2013-09-09  
&X-Amz-Algorithm=AWS4-HMAC-SHA256  
&X-Amz-Credential=AKIADQKE4SARGYLE/20140429/us-west-1/rds/aws4_request  
&X-Amz-Date=20140429T175351Z  
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date  
&X-Amz-Signature=9164337efa99caf850e874a1cb7ef62f3cea29d0b448b9e0e7c53b288ddffed2
```

Example from unencrypted, across Regions

The following code creates a copy of a snapshot, with the new name mydbsnapshotcopy, in the US West (N. California) Region.

```
https://rds.us-west-1.amazonaws.com/  
?Action=CopyDBSnapshot

Sharing a DB snapshot

Using Amazon RDS, you can share a manual DB snapshot in the following ways:

- Sharing a manual DB snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to copy the snapshot.
- Sharing an unencrypted manual DB snapshot enables authorized AWS accounts to directly restore a DB instance from the snapshot instead of taking a copy of it and restoring from that. However, you can't restore a DB instance from a DB snapshot that is both shared and encrypted. Instead, you can make a copy of the DB snapshot and restore the DB instance from the copy.

Note

To share an automated DB snapshot, create a manual DB snapshot by copying the automated snapshot, and then share that copy. This process also applies to AWS Backup-generated resources.

For more information on copying a snapshot, see [Copying a DB snapshot \(p. 458\)](#). For more information on restoring a DB instance from a DB snapshot, see [Restoring from a DB snapshot \(p. 452\)](#).

You can share a manual snapshot with up to 20 other AWS accounts.

The following limitations apply when sharing manual snapshots with other AWS accounts:

- When you restore a DB instance from a shared snapshot using the AWS Command Line Interface (AWS CLI) or Amazon RDS API, you must specify the Amazon Resource Name (ARN) of the shared snapshot as the snapshot identifier.
- You can't share a DB snapshot that uses an option group with permanent or persistent options, except for Oracle DB instances that have the Timezone or OLS option (or both).

A *permanent option* can't be removed from an option group. Option groups with persistent options can't be removed from a DB instance once the option group has been assigned to the DB instance.

The following table lists permanent and persistent options and their related DB engines.

Option name	Persistent	Permanent	DB engine
TDE	Yes	No	Microsoft SQL Server Enterprise Edition
TDE	Yes	Yes	Oracle Enterprise Edition
Timezone	Yes	Yes	Oracle Enterprise Edition
			Oracle Standard Edition
			Oracle Standard Edition One
			Oracle Standard Edition Two

For Oracle DB instances, you can copy shared DB snapshots that have the Timezone or OLS option (or both). To do so, specify a target option group that includes these options when you copy the DB snapshot. The OLS option is permanent and persistent only for Oracle DB instances running Oracle version 12.2 or higher. For more information about these options, see [Oracle time zone \(p. 1742\)](#) and [Oracle Label Security \(p. 1703\)](#).

Sharing public snapshots

You can also share an unencrypted manual snapshot as public, which makes the snapshot available to all AWS accounts. Make sure when sharing a snapshot as public that none of your private information is included in the public snapshot.

When a snapshot is shared publicly, it gives all AWS accounts permission both to copy the snapshot and to create DB instances from it.

You aren't billed for the backup storage of public snapshots owned by other accounts. You're billed only for snapshots that you own.

If you copy a public snapshot, you own the copy. You're billed for the backup storage of your snapshot copy. If you create a DB instance from a public snapshot, you're billed for that DB instance. For Amazon RDS pricing information, see the [Amazon RDS product page](#).

You can delete only the public snapshots that you own. To delete a shared or public snapshot, make sure to log into the AWS account that owns the snapshot.

Viewing public snapshots owned by other AWS accounts

You can view public snapshots owned by other accounts in a particular AWS Region on the **Public** tab of the **Snapshots** page in the Amazon RDS console. Your snapshots (those owned by your account) don't appear on this tab.

To view public snapshots

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Public** tab.

The public snapshots appear. You can see which account owns a public snapshot in the **Owner** column.

Note

You might have to modify the page preferences, by selecting the gear icon at the upper right of the **Public snapshots** list, to see this column.

Viewing your own public snapshots

You can use the following AWS CLI command (Unix only) to view the public snapshots owned by your AWS account in a particular AWS Region.

```
aws rds describe-db-snapshots --snapshot-type public --include-public | grep account_number
```

The output returned is similar to the following example if you have public snapshots.

```
"DBSnapshotArn": "arn:aws:rds:us-east-1:123456789012:snapshot:mysnapshot1",
"DBSnapshotArn": "arn:aws:rds:us-east-1:123456789012:snapshot:mysnapshot2",
```

Note

You might see duplicate entries for `DBSnapshotIdentifier` or `SourceDBSnapshotIdentifier`.

Sharing encrypted snapshots

You can share DB snapshots that have been encrypted "at rest" using the AES-256 encryption algorithm, as described in [Encrypting Amazon RDS resources \(p. 2000\)](#). To do this, take the following steps:

1. Share the AWS KMS key that was used to encrypt the snapshot with any accounts that you want to be able to access the snapshot.

You can share KMS keys with another AWS account by adding the other account to the KMS key policy. For details on updating a key policy, see [Key policies](#) in the *AWS KMS Developer Guide*. For an example of creating a key policy, see [Allowing access to an AWS KMS key \(p. 474\)](#) later in this topic.

2. Use the AWS Management Console, AWS CLI, or Amazon RDS API to share the encrypted snapshot with the other accounts.

These restrictions apply to sharing encrypted snapshots:

- You can't share encrypted snapshots as public.
- You can't share Oracle or Microsoft SQL Server snapshots that are encrypted using Transparent Data Encryption (TDE).
- You can't share a snapshot that has been encrypted using the default KMS key of the AWS account that shared the snapshot.

Allowing access to an AWS KMS key

For another AWS account to copy an encrypted DB snapshot shared from your account, the account that you share your snapshot with must have access to the AWS KMS key that encrypted the snapshot.

To allow another AWS account access to a KMS key, update the key policy for the KMS key. You update it with the Amazon Resource Name (ARN) of the AWS account that you are sharing to as `Principal` in the KMS key policy. Then you allow the `kms:CreateGrant` action.

After you have given an AWS account access to your KMS key, to copy your encrypted snapshot that AWS account must create an AWS Identity and Access Management (IAM) role or user if it doesn't already have one. In addition, that AWS account must also attach an IAM policy to that IAM role or user that allows the role or user to copy an encrypted DB snapshot using your KMS key. The account must be an IAM user and can't be a root AWS account identity due to AWS KMS security restrictions.

In the following key policy example, user 111122223333 is the owner of the KMS key, and user 444455556666 is the account that the key is being shared with. This updated key policy gives the AWS account access to the KMS key by including the ARN for the root AWS account identity for user 444455556666 as a `Principal` for the policy, and by allowing the `kms:CreateGrant` action.

```
{  
    "Id": "key-policy-1",  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Allow use of the key",  
            "Effect": "Allow",  
            "Principal": {"AWS": [  
                "arn:aws:iam::111122223333:user/KeyUser",  
                "arn:aws:iam::444455556666:root"  
            ]},  
            "Action": [  
                "kms:CreateGrant",  
                "kms:Decrypt",  
                "kms:DescribeKey",  
                "kms:Encrypt",  
                "kms:GenerateDataKey",  
                "kms:GenerateDataKeyWithoutPlaintext",  
                "kms:ListAliases",  
                "kms:ListKeys",  
                "kms:ReEncryptFrom",  
                "kms:ReEncryptTo",  
                "kms:UpdateKeyDescription",  
                "kms:UpdateKeyPolicy"  
            ]  
        }  
    ]  
}
```

```

        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
    ],
    "Resource": "*"
},
{
    "Sid": "Allow attachment of persistent resources",
    "Effect": "Allow",
    "Principal": {"AWS": [

        "arn:aws:iam::444455556666:root"
    ]},
    "Action": [
        "kms:CreateGrant",
        "kms>ListGrants",
        "kms:RevokeGrant"
    ],
    "Resource": "*",
    "Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
}
]
}

```

Creating an IAM policy to enable copying of the encrypted snapshot

Once the external AWS account has access to your KMS key, the owner of that AWS account can create a policy that allows an IAM user created for that account to copy an encrypted snapshot encrypted with that KMS key.

The following example shows a policy that can be attached to an IAM user for AWS account 444455556666 that enables the IAM user to copy a shared snapshot from AWS account 111122223333 that has been encrypted with the KMS key c989c1dd-a3f2-4a5d-8d96-e793d082ab26 in the us-west-2 region.

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowUseOfTheKey",
            "Effect": "Allow",
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*",
                "kms:DescribeKey",
                "kms>CreateGrant",
                "kms:RetireGrant"
            ],
            "Resource": ["arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-e793d082ab26"]
        },
        {
            "Sid": "AllowAttachmentOfPersistentResources",
            "Effect": "Allow",
            "Action": [
                "kms>CreateGrant",
                "kms>ListGrants",
                "kms:RevokeGrant"
            ]
        }
    ]
}

```

```
        ],
        "Resource": ["arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-
e793d082ab26"],
        "Condition": {
            "Bool": {
                "kms:GrantIsForAWSResource": true
            }
        }
    ]
}
```

For details on updating a key policy, see [Key policies in the AWS KMS Developer Guide](#).

Sharing a snapshot

You can share a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

Using the Amazon RDS console, you can share a manual DB snapshot with up to 20 AWS accounts. You can also use the console to stop sharing a manual snapshot with one or more accounts.

To share a manual DB snapshot by using the Amazon RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the manual snapshot that you want to share.
4. For **Actions**, choose **Share Snapshot**.
5. Choose one of the following options for **DB snapshot visibility**.
 - If the source is unencrypted, choose **Public** to permit all AWS accounts to restore a DB instance from your manual DB snapshot, or choose **Private** to permit only AWS accounts that you specify to restore a DB instance from your manual DB snapshot.

Warning

If you set **DB snapshot visibility** to **Public**, all AWS accounts can restore a DB instance from your manual DB snapshot and have access to your data. Do not share any manual DB snapshots that contain private information as **Public**.

- If the source is encrypted, **DB snapshot visibility** is set as **Private** because encrypted snapshots can't be shared as public.
6. For **AWS Account ID**, type the AWS account identifier for an account that you want to permit to restore a DB instance from your manual snapshot, and then choose **Add**. Repeat to include additional AWS account identifiers, up to 20 AWS accounts.

If you make an error when adding an AWS account identifier to the list of permitted accounts, you can delete it from the list by choosing **Delete** at the right of the incorrect AWS account identifier.

Snapshot permissions

Preferences

You are sharing an unencrypted DB snapshot. When you share an unencrypted DB snapshot, you give the other account permission to make a copy of the DB snapshot and to restore a database from your DB snapshot.

Save

- After you have added identifiers for all of the AWS accounts that you want to permit to restore the manual snapshot, choose **Save** to save your changes.

To stop sharing a manual DB snapshot with an AWS account

- Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
- In the navigation pane, choose **Snapshots**.
- Select the manual snapshot that you want to stop sharing.
- Choose **Actions**, and then choose **Share Snapshot**.
- To remove permission for an AWS account, choose **Delete** for the AWS account identifier for that account from the list of authorized accounts.

Snapshot permissions

Preferences

You are sharing an unencrypted DB snapshot. When you share an unencrypted DB snapshot, you give the other account permission to make a copy of the DB snapshot and to restore a database from your DB snapshot.

AWS CLI

To share a DB snapshot, use the `aws rds modify-db-snapshot-attribute` command. Use the `--values-to-add` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

Example of sharing a snapshot with a single account

The following example enables AWS account identifier 123456789012 to restore the DB snapshot named db7-snapshot.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot-attribute \
--db-snapshot-identifier db7-snapshot \
--attribute-name restore \
--values-to-add 123456789012
```

For Windows:

```
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier db7-snapshot ^
--attribute-name restore ^
--values-to-add 123456789012
```

Example of sharing a snapshot with multiple accounts

The following example enables two AWS account identifiers, 111122223333 and 444455556666, to restore the DB snapshot named manual-snapshot1.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot-attribute \
--db-snapshot-identifier manual-snapshot1 \
--attribute-name restore \
--values-to-add {"111122223333","444455556666"}
```

For Windows:

```
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier manual-snapshot1 ^
--attribute-name restore ^
--values-to-add "[\"111122223333\", \"444455556666\"]"
```

Note

When using the Windows command prompt, you must escape double quotes ("") in JSON code by prefixing them with a backslash (\).

To remove an AWS account identifier from the list, use the --values-to-remove parameter.

Example of stopping snapshot sharing

The following example prevents AWS account ID 444455556666 from restoring the snapshot.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot-attribute \
--db-snapshot-identifier manual-snapshot1 \
--attribute-name restore \
--values-to-remove 444455556666
```

For Windows:

```
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier manual-snapshot1 ^
--attribute-name restore ^
--values-to-remove 444455556666
```

To list the AWS accounts enabled to restore a snapshot, use the [describe-db-snapshot-attributes](#) AWS CLI command.

RDS API

You can also share a manual DB snapshot with other AWS accounts by using the Amazon RDS API. To do so, call the [ModifyDBSnapshotAttribute](#) operation. Specify `restore` for `AttributeName`, and use the `ValuesToAdd` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

To make a manual snapshot public and restorable by all AWS accounts, use the value `all`. However, take care not to add the `all` value for any manual snapshots that contain private information that you don't want to be available to all AWS accounts. Also, don't specify `all` for encrypted snapshots, because making such snapshots public isn't supported.

To remove sharing permission for an AWS account, use the [ModifyDBSnapshotAttribute](#) operation with `AttributeName` set to `restore` and the `ValuesToRemove` parameter. To mark a manual snapshot as private, remove the value `all` from the values list for the `restore` attribute.

To list all of the AWS accounts permitted to restore a snapshot, use the [DescribeDBSnapshotAttributes](#) API operation.

Exporting DB snapshot data to Amazon S3

You can export DB snapshot data to an Amazon S3 bucket. The export process runs in the background and doesn't affect the performance of your active DB instance.

When you export a DB snapshot, Amazon RDS extracts data from the snapshot and stores it in an Amazon S3 bucket. The data is stored in an Apache Parquet format that is compressed and consistent.

You can export all types of DB snapshots—including manual snapshots, automated system snapshots, and snapshots created by the AWS Backup service. By default, all data in the snapshot is exported. However, you can choose to export specific sets of databases, schemas, or tables.

After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information on using Athena to read Parquet data, see [Parquet SerDe](#) in the *Amazon Athena User Guide*. For more information on using Redshift Spectrum to read Parquet data, see [COPY from columnar data formats](#) in the *Amazon Redshift Database Developer Guide*.

- [File naming convention \(p. 492\)](#)
- [Data conversion when exporting to an Amazon S3 bucket \(p. 493\)](#)

Region and version availability

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information on version and Region availability with exporting snapshots to S3, see [Export snapshots to S3 \(p. 95\)](#).

Limitations

Exporting DB snapshot data to Amazon S3 has the following limitations:

- Exporting snapshots from DB instances that use magnetic storage isn't supported.
- The following characters in the S3 file path are converted to underscores (_) during export:

\ ` " (space)

- If a database, schema, or table has characters in its name other than the following, partial export isn't supported. However, you can export the entire DB snapshot.
 - Latin letters (A–Z)
 - Digits (0–9)
 - Dollar symbol (\$)

- Underscore (_)
- Spaces () and certain characters aren't supported in database table column names. Tables with the following characters in column names are skipped during export:

```
, ; { } ( ) \n \t = (space)
```

- Tables with slashes (/) in their names are skipped during export.
- If the data contains a large object, such as a BLOB or CLOB, that is close to or greater than 500 MB, then the export fails.
- If a table contains a large row that is close to or greater than 2 GB, then the table is skipped during export.
- We strongly recommend that you use a unique name for each export task. If you don't use a unique task name, you might receive the following error message:

ExportTaskAlreadyExistsFault: An error occurred (ExportTaskAlreadyExists) when calling the StartExportTask operation: The export task with the ID **xxxxx** already exists.

- You can delete a snapshot while you're exporting its data to S3, but you're still charged for the storage costs for that snapshot until the export task has completed.
- You can't restore exported snapshot data from S3 to a new DB instance.

Overview of exporting snapshot data

You use the following process to export DB snapshot data to an Amazon S3 bucket. For more details, see the following sections.

1. Identify the snapshot to export.

Use an existing automated or manual snapshot, or create a manual snapshot of a DB instance.

2. Set up access to the Amazon S3 bucket.

A *bucket* is a container for Amazon S3 objects or files. To provide the information to access a bucket, take the following steps:

- a. Identify the S3 bucket where the snapshot is to be exported to. The S3 bucket must be in the same AWS Region as the snapshot. For more information, see [Identifying the Amazon S3 bucket for export \(p. 483\)](#).
- b. Create an AWS Identity and Access Management (IAM) role that grants the snapshot export task access to the S3 bucket. For more information, see [Providing access to an Amazon S3 bucket using an IAM role \(p. 483\)](#).
3. Create a symmetric encryption AWS KMS key for the server-side encryption. The KMS key is used by the snapshot export task to set up AWS KMS server-side encryption when writing the export data to S3. For more information, see [Encrypting Amazon RDS resources \(p. 2000\)](#).

The KMS key is also used for local disk encryption at rest on Amazon EC2. In addition, if you have a deny statement in your KMS key policy, make sure to explicitly exclude the AWS service principal `export.rds.amazonaws.com`.

You can use a KMS key within your AWS account, or you can use a cross-account KMS key. For more information, see [Using a cross-account AWS KMS key for encrypting Amazon S3 exports \(p. 485\)](#).

4. Export the snapshot to Amazon S3 using the console or the `start-export-task` CLI command. For more information, see [Exporting a DB snapshot to an Amazon S3 bucket \(p. 486\)](#).
5. To access your exported data in the Amazon S3 bucket, see [Uploading, downloading, and managing objects in the Amazon Simple Storage Service User Guide](#).

Setting up access to an Amazon S3 bucket

To export DB snapshot data to an Amazon S3 file, you first give the snapshot permission to access the Amazon S3 bucket. You then create an IAM role to allow the Amazon RDS service to write to the Amazon S3 bucket.

Topics

- [Identifying the Amazon S3 bucket for export \(p. 483\)](#)
- [Providing access to an Amazon S3 bucket using an IAM role \(p. 483\)](#)
- [Using a cross-account Amazon S3 bucket \(p. 485\)](#)

Identifying the Amazon S3 bucket for export

Identify the Amazon S3 bucket to export the DB snapshot to. Use an existing S3 bucket or create a new S3 bucket.

Note

The S3 bucket to export to must be in the same AWS Region as the snapshot.

For more information about working with Amazon S3 buckets, see the following in the *Amazon Simple Storage Service User Guide*:

- [How do I view the properties for an S3 bucket?](#)
- [How do I enable default encryption for an Amazon S3 bucket?](#)
- [How do I create an S3 bucket?](#)

Providing access to an Amazon S3 bucket using an IAM role

Before you export DB snapshot data to Amazon S3, give the snapshot export tasks write-access permission to the Amazon S3 bucket.

To grant this permission, create an IAM policy that provides access to the bucket, then create an IAM role and attach the policy to the role. You later assign the IAM role to your snapshot export task.

Important

If you plan to use the AWS Management Console to export your snapshot, you can choose to create the IAM policy and the role automatically when you export the snapshot. For instructions, see [Exporting a DB snapshot to an Amazon S3 bucket \(p. 486\)](#).

To give DB snapshot tasks access to Amazon S3

1. Create an IAM policy. This policy provides the bucket and object permissions that allow your snapshot export task to access Amazon S3.

In the policy, include the following required actions to allow the transfer of files from Amazon RDS to an S3 bucket:

- `s3:PutObject*`
- `s3:GetObject*`
- `s3>ListBucket`
- `s3>DeleteObject*`
- `s3:GetBucketLocation`

In the policy, include the following resources to identify the S3 bucket and objects in the bucket. The following list of resources shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

- `arn:aws:s3:::your-s3-bucket`
- `arn:aws:s3:::your-s3-bucket/*`

For more information on creating an IAM policy for Amazon RDS, see [Creating and using an IAM policy for IAM database access \(p. 2051\)](#). See also [Tutorial: Create and attach your first customer managed policy](#) in the *IAM User Guide*.

The following AWS CLI command creates an IAM policy named `ExportPolicy` with these options. It grants access to a bucket named `your-s3-bucket`.

Note

After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy --policy-name ExportPolicy --policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "ExportPolicy",  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject*",  
                "s3>ListBucket",  
                "s3:GetObject*",  
                "s3>DeleteObject*",  
                "s3:GetBucketLocation"  
            ],  
            "Resource": [  
                "arn:aws:s3:::your-s3-bucket",  
                "arn:aws:s3:::your-s3-bucket/*"  
            ]  
        }  
    ]  
}'
```

2. Create an IAM role, so that Amazon RDS can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

The following example shows using the AWS CLI command to create a role named `rds-s3-export-role`.

```
aws iam create-role --role-name rds-s3-export-role --assume-role-policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "export.rds.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}'
```

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named `rds-s3-export-role`. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role
```

Using a cross-account Amazon S3 bucket

You can use Amazon S3 buckets across AWS accounts. To use a cross-account bucket, add a bucket policy to allow access to the IAM role that you're using for the S3 exports. For more information, see [Example 2: Bucket owner granting cross-account bucket permissions](#).

- Attach a bucket policy to your bucket, as shown in the following example.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:role/Admin"  
            },  
            "Action": [  
                "s3:PutObject*",  
                "s3>ListBucket",  
                "s3:GetObject*",  
                "s3>DeleteObject*",  
                "s3:GetBucketLocation"  
            ],  
            "Resource": [  
                "arn:aws:s3:::mycrossaccountbucket",  
                "arn:aws:s3:::mycrossaccountbucket/*"  
            ]  
        }  
    ]  
}
```

Using a cross-account AWS KMS key for encrypting Amazon S3 exports

You can use a cross-account AWS KMS key to encrypt Amazon S3 exports. First, you add a key policy to the local account, then you add IAM policies in the external account. For more information, see [Allowing users in other accounts to use a KMS key](#).

To use a cross-account KMS key

1. Add a key policy to the local account.

The following example gives `ExampleRole` and `ExampleUser` in the external account `444455556666` permissions in the local account `123456789012`.

```
{  
    "Sid": "Allow an external account to use this KMS key",  
    "Effect": "Allow",  
    "Principal": {
```

```
        "AWS": [
            "arn:aws:iam::444455556666:role/ExampleRole",
            "arn:aws:iam::444455556666:user/ExampleUser"
        ],
        "Action": [
            "kms:Encrypt",
            "kms:Decrypt",
            "kms:ReEncrypt*",
            "kms:GenerateDataKey*",
            "kms>CreateGrant",
            "kms:DescribeKey",
            "kms:RetireGrant"
        ],
        "Resource": "*"
    }
```

2. Add IAM policies to the external account.

The following example IAM policy allows the principal to use the KMS key in account 123456789012 for cryptographic operations. To give this permission to ExampleRole and ExampleUser in account 444455556666, [attach the policy](#) to them in that account.

```
{
    "Sid": "Allow use of KMS key in account 123456789012",
    "Effect": "Allow",
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms>CreateGrant",
        "kms:DescribeKey",
        "kms:RetireGrant"
    ],
    "Resource": "arn:aws:kms:us-
west-2:123456789012:key/1234abcd-12ab-34cd-56ef-1234567890ab"
}
```

Exporting a DB snapshot to an Amazon S3 bucket

You can have up to five concurrent DB snapshot export tasks in progress per AWS account.

Note

Exporting RDS snapshots can take a while depending on your database type and size. The export task first restores and scales the entire database before extracting the data to Amazon S3. The task's progress during this phase displays as **Starting**. When the task switches to exporting data to S3, progress displays as **In progress**.

The time it takes for the export to complete depends on the data stored in the database. For example, tables with well-distributed numeric primary key or index columns export the fastest. Tables that don't contain a column suitable for partitioning and tables with only one index on a string-based column take longer. This longer export time occurs because the export uses a slower single-threaded process.

You can export a DB snapshot to Amazon S3 using the AWS Management Console, the AWS CLI, or the RDS API.

If you use a Lambda function to export a snapshot, add the kms:DescribeKey action to the Lambda function policy. For more information, see [AWS Lambda permissions](#).

Console

The **Export to Amazon S3** console option appears only for snapshots that can be exported to Amazon S3. A snapshot might not be available for export because of the following reasons:

- The DB engine isn't supported for S3 export.
- The DB instance version isn't supported for S3 export.
- S3 export isn't supported in the AWS Region where the snapshot was created.

To export a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. From the tabs, choose the type of snapshot that you want to export.
4. In the list of snapshots, choose the snapshot that you want to export.
5. For **Actions**, choose **Export to Amazon S3**.

The **Export to Amazon S3** window appears.

6. For **Export identifier**, enter a name to identify the export task. This value is also used for the name of the file created in the S3 bucket.
7. Choose the data to be exported:
 - Choose **All** to export all data in the snapshot.
 - Choose **Partial** to export specific parts of the snapshot. To identify which parts of the snapshot to export, enter one or more databases, schemas, or tables for **Identifiers**, separated by spaces.

Use the following format:

```
database[.schema][.table] database2[.schema2][.table2] ... databasen[.scheman]  
[.tablen]
```

For example:

```
mydatabase mydatabase2.myschema1 mydatabase2.myschema2.mytable1  
mydatabase2.myschema2.mytable2
```

8. For **S3 bucket**, choose the bucket to export to.

To assign the exported data to a folder path in the S3 bucket, enter the optional path for **S3 prefix**.

9. For **IAM role**, either choose a role that grants you write access to your chosen S3 bucket, or create a new role.
 - If you created a role by following the steps in [Providing access to an Amazon S3 bucket using an IAM role \(p. 483\)](#), choose that role.
 - If you didn't create a role that grants you write access to your chosen S3 bucket, then choose **Create a new role** to create the role automatically. Next, enter a name for the role in **IAM role name**.
10. For **AWS KMS key**, enter the ARN for the key to use for encrypting the exported data.
11. Choose **Export to Amazon S3**.

AWS CLI

To export a DB snapshot to Amazon S3 using the AWS CLI, use the [start-export-task](#) command with the following required options:

- --export-task-identifier
- --source-arn
- --s3-bucket-name
- --iam-role-arn
- --kms-key-id

In the following examples, the snapshot export task is named *my-snapshot-export*, which exports a snapshot to an S3 bucket named *my-export-bucket*.

Example

For Linux, macOS, or Unix:

```
aws rds start-export-task \
  --export-task-identifier my-snapshot-export \
  --source-arn arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot-name \
  --s3-bucket-name my-export-bucket \
  --iam-role-arn iam-role \
  --kms-key-id my-key
```

For Windows:

```
aws rds start-export-task ^
  --export-task-identifier my-snapshot-export ^
  --source-arn arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot-name ^
  --s3-bucket-name my-export-bucket ^
  --iam-role-arn iam-role ^
  --kms-key-id my-key
```

Sample output follows.

```
{  
    "Status": "STARTING",  
    "IamRoleArn": "iam-role",  
    "ExportTime": "2019-08-12T01:23:53.109Z",  
    "S3Bucket": "my-export-bucket",  
    "PercentProgress": 0,  
    "KmsKeyId": "my-key",  
    "ExportTaskIdentifier": "my-snapshot-export",  
    "TotalExtractedDataInGB": 0,  
    "TaskStartTime": "2019-11-13T19:46:00.173Z",  
    "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot-name"  
}
```

To provide a folder path in the S3 bucket for the snapshot export, include the `--s3-prefix` option in the [start-export-task](#) command.

RDS API

To export a DB snapshot to Amazon S3 using the Amazon RDS API, use the [StartExportTask](#) operation with the following required parameters:

- ExportTaskIdentifier

- `SourceArn`
- `S3BucketName`
- `IamRoleArn`
- `KmsKeyId`

Monitoring snapshot exports

You can monitor DB snapshot exports using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To monitor DB snapshot exports

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. To view the list of snapshot exports, choose the **Exports in Amazon S3** tab.
4. To view information about a specific snapshot export, choose the export task.

AWS CLI

To monitor DB snapshot exports using the AWS CLI, use the `describe-export-tasks` command.

The following example shows how to display current information about all of your snapshot exports.

Example

```
aws rds describe-export-tasks

{
    "ExportTasks": [
        {
            "Status": "CANCELED",
            "TaskEndTime": "2019-11-01T17:36:46.961Z",
            "S3Prefix": "something",
            "ExportTime": "2019-10-24T20:23:48.364Z",
            "S3Bucket": "examplebucket",
            "PercentProgress": 0,
            "KmsKeyId": "arn:aws:kms:AWS Region:123456789012:key/K7MDENG/bPxRfiCYEXAMPLEKEY",
            "ExportTaskIdentifier": "anewtest",
            "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
            "TotalExtractedDataInGB": 0,
            "TaskStartTime": "2019-10-25T19:10:58.885Z",
            "SourceArn": "arn:aws:rds:AWS Region:123456789012:snapshot:parameter-groups-test"
        },
        {
            "Status": "COMPLETE",
            "TaskEndTime": "2019-10-31T21:37:28.312Z",
            "WarningMessage": "{\"skippedTables\":[],\"skippedObjectives\":[],\"general\": [{\"reason\":\"FAILED_TO_EXTRACT_TABLES_LIST_FOR_DATABASE\"}]}",
            "S3Prefix": "",
            "ExportTime": "2019-10-31T06:44:53.452Z",
            "S3Bucket": "examplebucket1",
            "PercentProgress": 100,
            "KmsKeyId": "arn:aws:kms:AWS Region:123456789012:key/2Zp9Utk/h3yCo8nvbEXAMPLEKEY",
        }
    ]
}
```

```
"ExportTaskIdentifier": "thursday-events-test",
"IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
"TotalExtractedDataInGB": 263,
"TaskStartTime": "2019-10-31T20:58:06.998Z",
"SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:rds:example-1-2019-10-31-06-44"
},
{
    "Status": "FAILED",
    "TaskEndTime": "2019-10-31T02:12:36.409Z",
    "FailureCause": "The S3 bucket edgcuc-export isn't located in the current AWS Region. Please, review your S3 bucket name and retry the export.",
    "S3Prefix": "",
    "ExportTime": "2019-10-30T06:45:04.526Z",
    "S3Bucket": "examplebucket2",
    "PercentProgress": 0,
    "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/2Zp9Utk/h3yCo8nvbEXAMPLEKEY",
    "ExportTaskIdentifier": "wednesday-afternoon-test",
    "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
    "TotalExtractedDataInGB": 0,
    "TaskStartTime": "2019-10-30T22:43:40.034Z",
    "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:rds:example-1-2019-10-30-06-45"
}
]
```

To display information about a specific snapshot export, include the `--export-task-identifier` option with the `describe-export-tasks` command. To filter the output, include the `--Filters` option. For more options, see the [describe-export-tasks](#) command.

RDS API

To display information about DB snapshot exports using the Amazon RDS API, use the [DescribeExportTasks](#) operation.

To track completion of the export workflow or to initiate another workflow, you can subscribe to Amazon Simple Notification Service topics. For more information on Amazon SNS, see [Working with Amazon RDS event notification \(p. 650\)](#).

Canceling a snapshot export task

You can cancel a DB snapshot export task using the AWS Management Console, the AWS CLI, or the RDS API.

Note

Canceling a snapshot export task doesn't remove any data that was exported to Amazon S3. For information about how to delete the data using the console, see [How do I delete objects from an S3 bucket?](#) To delete the data using the CLI, use the `delete-object` command.

Console

To cancel a snapshot export task

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Exports in Amazon S3** tab.
4. Choose the snapshot export task that you want to cancel.
5. Choose **Cancel**.

6. Choose **Cancel export task** on the confirmation page.

AWS CLI

To cancel a snapshot export task using the AWS CLI, use the [cancel-export-task](#) command. The command requires the `--export-task-identifier` option.

Example

```
aws rds cancel-export-task --export-task-identifier my_export
{
    "Status": "CANCELING",
    "S3Prefix": "",
    "ExportTime": "2019-08-12T01:23:53.109Z",
    "S3Bucket": "examplebucket",
    "PercentProgress": 0,
    "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/bPxRfiCYEXAMPLEKEY",
    "ExportTaskIdentifier": "my_export",
    "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
    "TotalExtractedDataInGB": 0,
    "TaskStartTime": "2019-11-13T19:46:00.173Z",
    "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:export-example-1"
}
```

RDS API

To cancel a snapshot export task using the Amazon RDS API, use the [CancelExportTask](#) operation with the `ExportTaskIdentifier` parameter.

Failure messages for Amazon S3 export tasks

The following table describes the messages that are returned when Amazon S3 export tasks fail.

Failure message	Description
An unknown internal error occurred.	The task has failed because of an unknown error, exception, or failure.
An unknown internal error occurred writing the export task's metadata to the S3 bucket [bucket name].	The task has failed because of an unknown error, exception, or failure.
The RDS export failed to write the export task's metadata because it can't assume the IAM role [role ARN].	The export task assumes your IAM role to validate whether it is allowed to write metadata to your S3 bucket. If the task can't assume your IAM role, it fails.
The RDS export failed to write the export task's metadata to the S3 bucket [bucket name] using the IAM role [role ARN] with the KMS key [key ID]. Error code: [error code]	One or more permissions are missing, so the export task can't access the S3 bucket. This failure message is raised when receiving one of the following error codes: <ul style="list-style-type: none">• <code>AWSecurityTokenServiceException</code> with the error code <code>AccessDenied</code>• <code>AmazonS3Exception</code> with the error code <code>NoSuchBucket</code>, <code>AccessDenied</code>, <code>KMS.InvalidStateException</code>, <code>403 Forbidden</code>, or <code>KMS.DisabledException</code>

Failure message	Description
	These error codes indicate settings are misconfigured for the IAM role, S3 bucket, or KMS key.
The IAM role [role ARN] isn't authorized to call [S3 action] on the S3 bucket [bucket name]. Review your permissions and retry the export.	The IAM policy is misconfigured. Permission for the specific S3 action on the S3 bucket is missing, which causes the export task to fail.
KMS key check failed. Check the credentials on your KMS key and try again.	The KMS key credential check failed.
S3 credential check failed. Check the permissions on your S3 bucket and IAM policy.	The S3 credential check failed.
The S3 bucket [bucket name] isn't valid. Either it isn't located in the current AWS Region or it doesn't exist. Review your S3 bucket name and retry the export.	The S3 bucket is invalid.
The S3 bucket [bucket name] isn't located in the current AWS Region. Review your S3 bucket name and retry the export.	The S3 bucket is in the wrong AWS Region.

Troubleshooting PostgreSQL permissions errors

When exporting PostgreSQL databases to Amazon S3, you might see a PERMISSIONS_D0_NOT_EXIST error stating that certain tables were skipped. This error usually occurs when the superuser, which you specified when creating the DB instance, doesn't have permissions to access those tables.

To fix this error, run the following command:

```
GRANT ALL PRIVILEGES ON ALL TABLES IN SCHEMA schema_name TO superuser_name
```

For more information on superuser privileges, see [Master user account privileges \(p. 2087\)](#).

File naming convention

Exported data for specific tables is stored in the format *base_prefix/files*, where the base prefix is the following:

export_identifier/database_name/schema_name.table_name/

For example:

`export-1234567890123-459/rdststdb/rdststdb.DataInsert_7ADB5D19965123A2/`

There are two conventions for how files are named. The current convention is the following:

partition_index/part-00000-random_uuid.format-based_extension

For example:

```
1/part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet
2/part-00000-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet
3/part-00000-f5a991ab-59aa-7fa6-3333-d41eccd340a7-c000.gz.parquet
```

The older convention is the following:

```
part-partition_index-random_uuid.format-based_extension
```

For example:

```
part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet
part-00001-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet
part-00002-f5a991ab-59aa-7fa6-3333-d41eccd340a7-c000.gz.parquet
```

The file naming convention is subject to change. Therefore, when reading target tables, we recommend that you read everything inside the base prefix for the table.

Data conversion when exporting to an Amazon S3 bucket

When you export a DB snapshot to an Amazon S3 bucket, Amazon RDS converts data to, exports data in, and stores data in the Parquet format. For more information about Parquet, see the [Apache Parquet](#) website.

Parquet stores all data as one of the following primitive types:

- BOOLEAN
- INT32
- INT64
- INT96
- FLOAT
- DOUBLE
- BYTE_ARRAY – A variable-length byte array, also known as binary
- FIXED_LEN_BYTE_ARRAY – A fixed-length byte array used when the values have a constant size

The Parquet data types are few to reduce the complexity of reading and writing the format. Parquet provides logical types for extending primitive types. A *logical type* is implemented as an annotation with the data in a LogicalType metadata field. The logical type annotation explains how to interpret the primitive type.

When the STRING logical type annotates a BYTE_ARRAY type, it indicates that the byte array should be interpreted as a UTF-8 encoded character string. After an export task completes, Amazon RDS notifies you if any string conversion occurred. The underlying data exported is always the same as the data from the source. However, due to the encoding difference in UTF-8, some characters might appear different from the source when read in tools such as Athena.

For more information, see [Parquet logical type definitions](#) in the Parquet documentation.

Topics

MySQL and MariaDB data type mapping to Parquet

The following table shows the mapping from MySQL and MariaDB data types to Parquet data types when data is converted and exported to Amazon S3.

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
Numeric data types			
BIGINT	INT64		
BIGINT UNSIGNED	FIXED_LEN_BYTE_ARRAY(9)DECIMAL(20,0)		Parquet supports only signed types, so the mapping requires an additional byte (8 plus 1) to store the BIGINT_UNSIGNED type.
BIT	BYTE_ARRAY		
DECIMAL	INT32	DECIMAL(p,s)	If the source value is less than 2^{31} , it's stored as INT32.
	INT64	DECIMAL(p,s)	If the source value is 2^{31} or greater, but less than 2^{63} , it's stored as INT64.
	FIXED_LEN_BYTE_ARRAY(N)DECIMAL(p,s)		If the source value is 2^{63} or greater, it's stored as FIXED_LEN_BYTE_ARRAY(N).
	BYTE_ARRAY	STRING	Parquet doesn't support Decimal precision greater than 38. The Decimal value is converted to a string in a BYTE_ARRAY type and encoded as UTF8.
DOUBLE	DOUBLE		
FLOAT	DOUBLE		
INT	INT32		
INT UNSIGNED	INT64		
MEDIUMINT	INT32		
MEDIUMINT UNSIGNED	INT64		
NUMERIC	INT32	DECIMAL(p,s)	If the source value is less than 2^{31} , it's stored as INT32.

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
	INT64	DECIMAL(p,s)	If the source value is 2^{31} or greater, but less than 2^{63} , it's stored as INT64.
	FIXED_LEN_ARRAY(N)	DECIMAL(p,s)	If the source value is 2^{63} or greater, it's stored as FIXED_LEN_BYTE_ARRAY(N).
	BYTE_ARRAY	STRING	Parquet doesn't support Numeric precision greater than 38. This Numeric value is converted to a string in a BYTE_ARRAY type and encoded as UTF8.
SMALLINT	INT32		
SMALLINT UNSIGNED	INT32		
TINYINT	INT32		
TINYINT UNSIGNED	INT32		
String data types			
BINARY	BYTE_ARRAY		
BLOB	BYTE_ARRAY		
CHAR	BYTE_ARRAY		
ENUM	BYTE_ARRAY	STRING	
LINESTRING	BYTE_ARRAY		
LONGBLOB	BYTE_ARRAY		
LONGTEXT	BYTE_ARRAY	STRING	
MEDIUMBLOB	BYTE_ARRAY		
MEDIUMTEXT	BYTE_ARRAY	STRING	
MULTILINESTRING	BYTE_ARRAY		
SET	BYTE_ARRAY	STRING	
TEXT	BYTE_ARRAY	STRING	
TINYBLOB	BYTE_ARRAY		
TINYTEXT	BYTE_ARRAY	STRING	
VARBINARY	BYTE_ARRAY		
VARCHAR	BYTE_ARRAY	STRING	
Date and time data types			

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
DATE	BYTE_ARRAY	STRING	A date is converted to a string in a BYTE_ARRAY type and encoded as UTF8.
DATETIME	INT64	TIMESTAMP_MICROS	
TIME	BYTE_ARRAY	STRING	A TIME type is converted to a string in a BYTE_ARRAY and encoded as UTF8.
TIMESTAMP	INT64	TIMESTAMP_MICROS	
YEAR	INT32		
Geometric data types			
GEOMETRY	BYTE_ARRAY		
GEOMETRYCOLLECTION	BYTE_ARRAY		
MULTIPOINT	BYTE_ARRAY		
MULTIPOLYGON	BYTE_ARRAY		
POINT	BYTE_ARRAY		
POLYGON	BYTE_ARRAY		
JSON data type			
JSON	BYTE_ARRAY	STRING	

PostgreSQL data type mapping to Parquet

The following table shows the mapping from PostgreSQL data types to Parquet data types when data is converted and exported to Amazon S3.

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
Numeric data types			
BIGINT	INT64		
BIGSERIAL	INT64		
DECIMAL	BYTE_ARRAY	STRING	A DECIMAL type is converted to a string in a BYTE_ARRAY type and encoded as UTF8. This conversion is to avoid complications due to data precision and

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
			data values that are not a number (NaN).
DOUBLE PRECISION	DOUBLE		
INTEGER	INT32		
MONEY	BYTE_ARRAY	STRING	
REAL	FLOAT		
SERIAL	INT32		
SMALLINT	INT32	INT_16	
SMALLSERIAL	INT32	INT_16	
String and related data types			
ARRAY	BYTE_ARRAY	STRING	An array is converted to a string and encoded as BINARY (UTF8). This conversion is to avoid complications due to data precision, data values that are not a number (NaN), and time data values.
BIT	BYTE_ARRAY	STRING	
BIT VARYING	BYTE_ARRAY	STRING	
BYTEA	BINARY		
CHAR	BYTE_ARRAY	STRING	
CHAR(N)	BYTE_ARRAY	STRING	
ENUM	BYTE_ARRAY	STRING	
NAME	BYTE_ARRAY	STRING	
TEXT	BYTE_ARRAY	STRING	
TEXT SEARCH	BYTE_ARRAY	STRING	
VARCHAR(N)	BYTE_ARRAY	STRING	
XML	BYTE_ARRAY	STRING	
Date and time data types			
DATE	BYTE_ARRAY	STRING	
INTERVAL	BYTE_ARRAY	STRING	
TIME	BYTE_ARRAY	STRING	

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
TIME WITH TIME ZONE	BYTE_ARRAY	STRING	
TIMESTAMP	BYTE_ARRAY	STRING	
TIMESTAMP WITH TIME ZONE	BYTE_ARRAY	STRING	
Geometric data types			
BOX	BYTE_ARRAY	STRING	
CIRCLE	BYTE_ARRAY	STRING	
LINE	BYTE_ARRAY	STRING	
LINESEGMENT	BYTE_ARRAY	STRING	
PATH	BYTE_ARRAY	STRING	
POINT	BYTE_ARRAY	STRING	
POLYGON	BYTE_ARRAY	STRING	
JSON data types			
JSON	BYTE_ARRAY	STRING	
JSONB	BYTE_ARRAY	STRING	
Other data types			
BOOLEAN	BOOLEAN		
CIDR	BYTE_ARRAY	STRING	Network data type
COMPOSITE	BYTE_ARRAY	STRING	
DOMAIN	BYTE_ARRAY	STRING	
INET	BYTE_ARRAY	STRING	Network data type
MACADDR	BYTE_ARRAY	STRING	
OBJECT IDENTIFIER	N/A		
PG_LSN	BYTE_ARRAY	STRING	
RANGE	BYTE_ARRAY	STRING	
UUID	BYTE_ARRAY	STRING	

Restoring a DB instance to a specified time

You can restore a DB instance to a specific point in time, creating a new DB instance.

When you restore a DB instance to a point in time, you can choose the default virtual private cloud (VPC) security group. Or you can apply a custom VPC security group to your DB instance.

Restored DB instances are automatically associated with the default DB parameter and option groups. However, you can apply a custom parameter group and option group by specifying them during a restore.

RDS uploads transaction logs for DB instances to Amazon S3 every five minutes. To see the latest restorable time for a DB instance, use the AWS CLI `describe-db-instances` command and look at the value returned in the `LatestRestorableTime` field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose **Automated backups**.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose **Automated backups** in the Amazon RDS console.

DB Name	Earliest restorable time	Latest restorable time	Engine	Encrypted
database-1	December 27th 2020, 9:42:48 am UTC	January 4th 2021, 6:25:01 pm UTC	sqlserver-se	No
database-1-sast	December 31st 2020, 9:18:52 am UTC	January 8th 2021, 2:44:01 pm UTC	sqlserver-ex	No
database-2	December 24th 2020, 11:58:45 am UTC	January 8th 2021, 2:46:01 pm UTC	sqlserver-se	Yes
database-3	December 31st 2020, 9:51:23 am UTC	January 8th 2021, 2:43:01 pm UTC	sqlserver-ex	No
database-6	December 31st 2020, 6:54:19 am UTC	January 8th 2021, 2:42:01 pm UTC	sqlserver-ex	No
database-7	January 1st 2021, 12:21:52 pm UTC	January 8th 2021, 2:50:00 pm UTC	mysql	No
db4-5640	January 4th 2021, 7:11:04 pm UTC	January 8th 2021, 2:50:00 pm UTC	mysql	No
myoracleinstance-from-replicated-backup	December 24th 2020, 7:49:18 am UTC	January 8th 2021, 2:47:57 pm UTC	oracle-se2	No
test2-mysql-mag-maz	January 6th 2021, 6:42:52 am UTC	January 8th 2021, 2:50:00 pm UTC	mysql	No

Note

We recommend that you restore to the same or similar DB instance size—and IOPS if using Provisioned IOPS storage—as the source DB instance. You might get an error if, for example, you choose a DB instance size with an incompatible IOPS value.

Some of the database engines used by Amazon RDS have special considerations when restoring from a point in time:

- When you restore an Oracle DB instance to a point in time, you can specify a different Oracle DB engine, license model, and DBName (SID) to be used by the new DB instance.
- When you restore a Microsoft SQL Server DB instance to a point in time, each database within that instance is restored to a point in time within 1 second of each other database within the instance. Transactions that span multiple databases within the instance might be restored inconsistently.
- For a SQL Server DB instance, the OFFLINE, EMERGENCY, and SINGLE_USER modes aren't supported. Setting any database into one of these modes causes the latest restorable time to stop moving ahead for the whole instance.
- Some actions, such as changing the recovery model of a SQL Server database, can break the sequence of logs that are used for point-in-time recovery. In some cases, Amazon RDS can detect this issue and the latest restorable time is prevented from moving forward. In other cases, such as when a SQL Server database uses the BULK_LOGGED recovery model, the break in log sequence isn't detected. It might not be possible to restore a SQL Server DB instance to a point in time if there is a break in the

log sequence. For these reasons, Amazon RDS doesn't support changing the recovery model of SQL Server databases.

You can also use AWS Backup to manage backups of Amazon RDS DB instances. If your DB instance is associated with a backup plan in AWS Backup, that backup plan is used for point-in-time recovery. Backups that were created with AWS Backup have names ending in awsbackup:*AWS-Backup-job-number*. For information about AWS Backup, see the [AWS Backup Developer Guide](#).

Note

Information in this topic applies to Amazon RDS. For information on restoring an Amazon Aurora DB cluster, see [Restoring a DB cluster to a specified time](#).

You can restore a DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore a DB instance to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Automated backups**.
The automated backups are displayed on the **Current Region** tab.
3. Choose the DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.
The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

If you chose **Custom**, enter the date and time to which you want to restore the instance.

Note

Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

6. For **DB instance identifier**, enter the name of the target restored DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class, storage, and whether you want to use storage autoscaling.

For information about each setting, see [Settings for DB instances \(p. 237\)](#).

8. Choose **Restore to point in time**.

AWS CLI

To restore a DB instance to a specified time, use the AWS CLI command `restore-db-instance-to-point-in-time` to create a new DB instance. This example also enables storage autoscaling.

You can specify other settings. For information about each setting, see [Settings for DB instances \(p. 237\)](#).

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
```

```
--source-db-instance-identifier mysourcedbinstance \
--target-db-instance-identifier mytargetdbinstance \
--restore-time 2017-10-14T23:45:00.000Z \
--max-allocated-storage 1000
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
--source-db-instance-identifier mysourcedbinstance ^
--target-db-instance-identifier mytargetdbinstance ^
--restore-time 2017-10-14T23:45:00.000Z ^
--max-allocated-storage 1000
```

RDS API

To restore a DB instance to a specified time, call the Amazon RDS API

[RestoreDBInstanceToPointInTime](#) operation with the following parameters:

- `SourceDBInstanceIdentifier`
- `TargetDBInstanceIdentifier`
- `RestoreTime`

Restoring a Multi-AZ DB cluster to a specified time

You can restore a Multi-AZ DB cluster to a specific point in time, creating a new Multi-AZ DB cluster.

RDS uploads transaction logs for Multi-AZ DB clusters to Amazon S3 continuously. You can restore to any point in time within your backup retention period. To see the earliest restorable time for a Multi-AZ DB cluster, use the AWS CLI `describe-db-clusters` command. Look at the value returned in the `EarliestRestorableTime` field for the DB cluster. To see the latest restorable time for a Multi-AZ DB cluster, look at the value returned in the `LatestRestorableTime` field for the DB cluster.

When you restore a Multi-AZ DB cluster to a point in time, you can choose the default VPC security group for your Multi-AZ DB cluster. Or you can apply a custom VPC security group to your Multi-AZ DB cluster.

Restored Multi-AZ DB clusters are automatically associated with the default DB cluster parameter group. However, you can apply a customer DB cluster parameter group by specifying it during a restore.

Note

We recommend that you restore to the same or similar Multi-AZ DB cluster size as the source DB cluster. We also recommend that you restore with the same or similar IOPS value if you're using Provisioned IOPS storage. You might get an error if, for example, you choose a DB cluster size with an incompatible IOPS value.

You can restore a Multi-AZ DB cluster to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore a Multi-AZ DB cluster to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Multi-AZ DB cluster that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

The **Restore to point in time** window appears.

5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

If you chose **Custom**, enter the date and time to which you want to restore the Multi-AZ DB cluster.

Note

Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

6. For **DB cluster identifier**, enter the name for your restored Multi-AZ DB cluster.
7. In **Availability and durability**, choose **Multi-AZ DB cluster**.

Availability and durability

Deployment options [Info](#)

The deployment options below are limited to those supported by the engine you selected above.

Multi-AZ DB cluster

Creates a DB cluster with a primary DB instance and two readable standby DB instances, with each DB instance in a different Availability Zone (AZ). Provides high availability, data redundancy and increases capacity to serve read workloads.

Multi-AZ DB instance

Creates a primary DB instance and a standby DB instance in a different AZ. Provides high availability and data redundancy, but the standby DB instance doesn't support connections for read workloads.

Single DB instance

Creates a single DB instance with no standby DB instances.

8. In **DB instance class**, choose a DB instance class.

Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see [DB instance classes \(p. 10\)](#).

9. For the remaining sections, specify your DB cluster settings. For information about each setting, see [Settings for creating Multi-AZ DB clusters \(p. 258\)](#).

10. Choose **Restore to point in time**.

AWS CLI

To restore a Multi-AZ DB cluster to a specified time, use the AWS CLI command [restore-db-cluster-to-point-in-time](#) to create a new Multi-AZ DB cluster.

Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see [DB instance classes \(p. 10\)](#).

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
--source-db-cluster-identifier mysourcemultiazdbcluster \
--db-cluster-identifier mytargetmultiazdbcluster \
--restore-to-time 2021-08-14T23:45:00.000Z \
--db-cluster-instance-class db.r6gd.xlarge
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
--source-db-cluster-identifier mysourcemultiazdbcluster ^
--db-cluster-identifier mytargetmultiazdbcluster ^
--restore-to-time 2021-08-14T23:45:00.000Z ^
--db-cluster-instance-class db.r6gd.xlarge
```

RDS API

To restore a DB cluster to a specified time, call the Amazon RDS API [RestoreDBClusterToPointInTime](#) operation with the following parameters:

- **SourceDBClusterIdentifier**
- **DBClusterIdentifier**

- `RestoreToTime`

Deleting a DB snapshot

You can delete DB snapshots managed by Amazon RDS when you no longer need them.

Note

To delete backups managed by AWS Backup, use the AWS Backup console. For information about AWS Backup, see the [AWS Backup Developer Guide](#).

Deleting a DB snapshot

You can delete a manual, shared, or public DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

To delete a shared or public snapshot, you must sign in to the AWS account that owns the snapshot.

If you have automated DB snapshots that you want to delete without deleting the DB instance, change the backup retention period for the DB instance to 0. The automated snapshots are deleted when the change is applied. You can apply the change immediately if you don't want to wait until the next maintenance period. After the change is complete, you can then re-enable automatic backups by setting the backup retention period to a number greater than 0. For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

If you deleted a DB instance, you can delete its automated DB snapshots by removing the automated backups for the DB instance. For information about automated backups, see [Working with backups \(p. 427\)](#).

Console

To delete a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.

The **Manual snapshots** list appears.

3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete snapshot**.
5. Choose **Delete** on the confirmation page.

AWS CLI

You can delete a DB snapshot by using the AWS CLI command `delete-db-snapshot`.

The following options are used to delete a DB snapshot.

- `--db-snapshot-identifier` – The identifier for the DB snapshot.

Example

The following code deletes the `mydbsnapshot` DB snapshot.

For Linux, macOS, or Unix:

```
aws rds delete-db-snapshot \
--db-snapshot-identifier mydbsnapshot
```

For Windows:

```
aws rds delete-db-snapshot ^
--db-snapshot-identifier mydbsnapshot
```

RDS API

You can delete a DB snapshot by using the Amazon RDS API operation [DeleteDBSnapshot](#).

The following parameters are used to delete a DB snapshot.

- **DBSnapshotIdentifier** – The identifier for the DB snapshot.

Tutorial: Restore an Amazon RDS DB instance from a DB snapshot

Often, when working with Amazon RDS you might have a DB instance that you work with occasionally but don't need full time. For example, suppose that you have a quarterly customer survey that uses an Amazon EC2 instance to host a customer survey website. You also have a DB instance that is used to store the survey results. One way to save money on such a scenario is to take a DB snapshot of the DB instance after the survey is completed. You then delete the DB instance and restore it when you need to conduct the survey again.

When you restore the DB instance, you provide the name of the DB snapshot to restore from. You then provide a name for the new DB instance that's created from the restore operation.

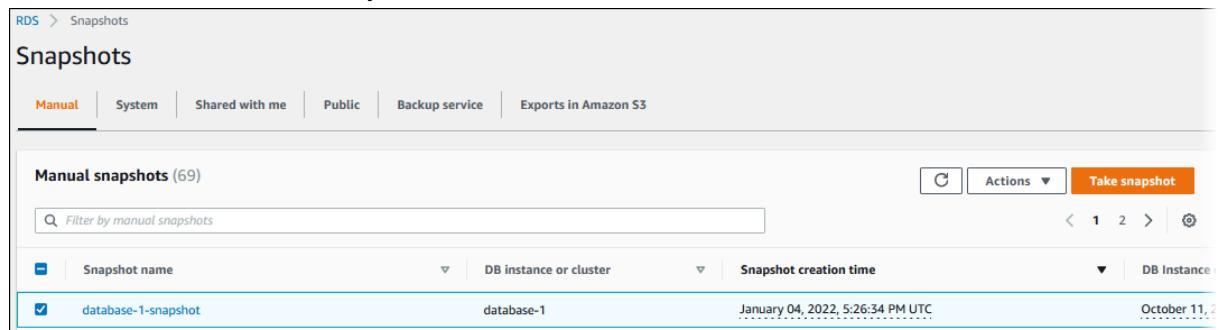

For more detailed information on restoring DB instances from snapshots, see [Restoring from a DB snapshot \(p. 452\)](#).

Restoring a DB instance from a DB snapshot

Use the following procedure to restore from a snapshot in the AWS Management Console.

To restore a DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.

The **Restore snapshot** page appears.

RDS > Snapshots > Restore snapshot

Restore snapshot

You are creating a new DB instance or DB cluster from a snapshot. The default VPC security group and parameter group are selected for the new DB instance or DB cluster, but you can change these settings.

DB instance settings

DB engine: SQL Server Express Edition

License model: license-included

Settings

DB snapshot ID: database-1-snapshot

DB instance identifier: mynewdbinstance

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

5. Under **DB instance settings**, use the default settings for **DB engine** and **License model** (for Oracle or Microsoft SQL Server).
6. Under **Settings**, for **DB instance identifier** enter the unique name that you want to use for the restored DB instance, for example **mynewdbinstance**.

If you're restoring from a DB instance that you deleted after you made the DB snapshot, you can use the name of that DB instance.
7. Under **Availability & durability**, for **Multi-AZ deployment** choose whether to create a standby instance in another Availability Zone.

For this tutorial, use **No**, the default setting.
8. Under **Connectivity**, use the default settings for the following:
 - **Virtual private cloud (VPC)**
 - **DB subnet group**
 - **Public access**
 - **VPC security group (firewall)**
9. Choose the **DB instance class**.

For this tutorial, choose **Burstable classes (includes t classes)**, and then choose **db.t3.small**.
10. For **Encryption**, use the default settings.

If the source DB instance for the snapshot was encrypted, the restored DB instance is also encrypted. You can't make it unencrypted.
11. Expand **Additional configuration** at the bottom of the page.

Additional configuration

Database options

DB parameter group [Info](#)
default.sqlserver-ex-15.0

Option group [Info](#)
default:sqlserver-ex-15-00

Collation [Info](#)

Backup

Copy tags to snapshots

Log exports

Select the log types to publish to Amazon CloudWatch Logs

Error log

IAM role

The following service-linked role is used for publishing logs to CloudWatch Logs.

RDS service-linked role

Maintenance

Auto minor version upgrade [Info](#)

Enable auto minor version upgrade
Enabling auto minor version upgrade will automatically upgrade to new minor versions as they are released.
The automatic upgrades occur during the maintenance window for the database.

Deletion protection

Enable deletion protection
Protects the database from being deleted accidentally. While this option is enabled, you can't delete the database.

12. Do the following under Database options:

- Choose the **DB parameter group**.

For this tutorial, use the default parameter group.

- Choose the **Option group**.

For this tutorial, use the default option group.

Important

In some cases, you might restore from a DB snapshot of a DB instance that uses a persistent or permanent option. If so, make sure to choose an option group that uses the same option.

- For **Deletion protection**, choose the **Enable deletion protection** check box.

13. Choose Restore DB instance.

The **Databases** page displays the restored DB instance, with a status of **Creating**.

	mynewdbinstance	Instance	SQL Server Express Edition	15.00.4073.23.v1	-	db.t3.small	
--	-----------------	----------	----------------------------	------------------	---	-------------	--

Monitoring metrics in an Amazon RDS instance

In the following sections, you can find an overview of Amazon RDS monitoring and an explanation about how to access metrics. To learn how to monitor events, logs, and database activity streams, see [Monitoring events, logs, and streams in an Amazon RDS DB instance \(p. 642\)](#).

Topics

- [Overview of monitoring metrics in Amazon RDS \(p. 511\)](#)
- [Viewing instance status and recommendations \(p. 515\)](#)
- [Viewing metrics in the Amazon RDS console \(p. 525\)](#)
- [Monitoring Amazon RDS metrics with Amazon CloudWatch \(p. 528\)](#)
- [Monitoring DB load with Performance Insights on Amazon RDS \(p. 543\)](#)
- [Monitoring OS metrics with Enhanced Monitoring \(p. 600\)](#)
- [Metrics reference for Amazon RDS \(p. 609\)](#)

Overview of monitoring metrics in Amazon RDS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your AWS solutions. To more easily debug multi-point failures, we recommend that you collect monitoring data from all parts of your AWS solution.

Topics

- [Monitoring plan \(p. 511\)](#)
- [Performance baseline \(p. 511\)](#)
- [Performance guidelines \(p. 511\)](#)
- [Monitoring tools \(p. 512\)](#)

Monitoring plan

Before you start monitoring Amazon RDS, create a monitoring plan. This plan should answer the following questions:

- What are your monitoring goals?
- Which resources will you monitor?
- How often will you monitor these resources?
- Which monitoring tools will you use?
- Who will perform the monitoring tasks?
- Whom should be notified when something goes wrong?

Performance baseline

To achieve your monitoring goals, you need to establish a baseline. To do this, measure performance under different load conditions at various times in your Amazon RDS environment. You can monitor metrics such as the following:

- Network throughput
- Client connections
- I/O for read, write, or metadata operations
- Burst credit balances for your DB instances

We recommend that you store historical performance data for Amazon RDS. Using the stored data, you can compare current performance against past trends. You can also distinguish normal performance patterns from anomalies, and devise techniques to address issues.

Performance guidelines

In general, acceptable values for performance metrics depend on what your application is doing relative to your baseline. Investigate consistent or trending variances from your baseline. The following metrics are often the source of performance issues:

- **High CPU or RAM consumption** – High values for CPU or RAM consumption might be appropriate, if they're in keeping with your goals for your application (like throughput or concurrency) and are expected.

- **Disk space consumption** – Investigate disk space consumption if space used is consistently at or above 85 percent of the total disk space. See if it is possible to delete data from the instance or archive data to a different system to free up space.
- **Network traffic** – For network traffic, talk with your system administrator to understand what expected throughput is for your domain network and internet connection. Investigate network traffic if throughput is consistently lower than expected.
- **Database connections** – If you see high numbers of user connections and also decreases in instance performance and response time, consider constraining database connections. The best number of user connections for your DB instance varies based on your instance class and the complexity of the operations being performed. To determine the number of database connections, associate your DB instance with a parameter group where the `User_Connections` parameter is set to a value other than 0 (unlimited). You can either use an existing parameter group or create a new one. For more information, see [Working with parameter groups \(p. 289\)](#).
- **IOPS metrics** – The expected values for IOPS metrics depend on disk specification and server configuration, so use your baseline to know what is typical. Investigate if values are consistently different than your baseline. For best IOPS performance, make sure that your typical working set fits into memory to minimize read and write operations.

When performance falls outside your established baseline, you might need to make changes to optimize your database availability for your workload. For example, you might need to change the instance class of your DB instance. Or you might need to change the number of DB instances and read replicas that are available for clients.

Monitoring tools

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your other AWS solutions. AWS provides various monitoring tools to watch Amazon RDS, report when something is wrong, and take automatic actions when appropriate.

Topics

- [Automated monitoring tools \(p. 512\)](#)
- [Manual monitoring tools \(p. 513\)](#)

Automated monitoring tools

We recommend that you automate monitoring tasks as much as possible.

Topics

- [Amazon RDS instance status and recommendations \(p. 512\)](#)
- [Amazon CloudWatch metrics for Amazon RDS \(p. 513\)](#)
- [Amazon RDS Performance Insights and operating-system monitoring \(p. 513\)](#)
- [Integrated services \(p. 513\)](#)

Amazon RDS instance status and recommendations

You can use the following automated tools to watch Amazon RDS and report when something is wrong:

- **Amazon RDS instance status** — View details about the current status of your instance by using the Amazon RDS console, the AWS CLI, or the RDS API.
- **Amazon RDS recommendations** — Respond to automated recommendations for database resources, such as DB instances, read replicas, and DB parameter groups. For more information, see [Viewing Amazon RDS recommendations \(p. 520\)](#).

Amazon CloudWatch metrics for Amazon RDS

Amazon RDS integrates with Amazon CloudWatch for additional monitoring capabilities.

- **Amazon CloudWatch** – This service monitors your AWS resources and the applications you run on AWS in real time. You can use the following Amazon CloudWatch features with Amazon RDS:
 - **Amazon CloudWatch metrics** – Amazon RDS automatically sends metrics to CloudWatch every minute for each active database. You don't get additional charges for Amazon RDS metrics in CloudWatch. For more information, see [Monitoring Amazon RDS metrics with Amazon CloudWatch \(p. 528\)](#).
 - **Amazon CloudWatch alarms** – You can watch a single Amazon RDS metric over a specific time period. You can then perform one or more actions based on the value of the metric relative to a threshold that you set. For more information, see [Monitoring Amazon RDS metrics with Amazon CloudWatch \(p. 528\)](#).

Amazon RDS Performance Insights and operating-system monitoring

You can use the following automated tools to monitor Amazon RDS performance:

- **Amazon RDS Performance Insights** – Assess the load on your database, and determine when and where to take action. For more information, see [Monitoring DB load with Performance Insights on Amazon RDS \(p. 543\)](#).
- **Amazon RDS Enhanced Monitoring** – Look at metrics in real time for the operating system. For more information, see [Monitoring OS metrics with Enhanced Monitoring \(p. 600\)](#).

Integrated services

The following AWS services are integrated with Amazon RDS:

- *Amazon EventBridge* is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. For more information, see [Monitoring Amazon RDS events \(p. 646\)](#).
- *Amazon CloudWatch Logs* lets you monitor, store, and access your log files from Amazon RDS instances, CloudTrail, and other sources. For more information, see [Monitoring Amazon RDS log files \(p. 680\)](#).
- *AWS CloudTrail* captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. For more information, see [Monitoring Amazon RDS API calls in AWS CloudTrail \(p. 725\)](#).
- *Database Activity Streams* is an Amazon RDS feature that provides a near-real-time stream of the activity in your Oracle DB instance. For more information, see [Monitoring Amazon RDS for Oracle with Database Activity Streams \(p. 729\)](#).

Manual monitoring tools

You need to manually monitor those items that the CloudWatch alarms don't cover. The Amazon RDS, CloudWatch, AWS Trusted Advisor and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on your DB instance.

- From the Amazon RDS console, you can monitor the following items for your resources:
 - The number of connections to a DB instance
 - The amount of read and write operations to a DB instance
 - The amount of storage that a DB instance is currently using
 - The amount of memory and CPU being used for a DB instance

- The amount of network traffic to and from a DB instance
- From the Trusted Advisor dashboard, you can review the following cost optimization, security, fault tolerance, and performance improvement checks:
 - Amazon RDS Idle DB Instances
 - Amazon RDS Security Group Access Risk
 - Amazon RDS Backups
 - Amazon RDS Multi-AZ

For more information on these checks, see [Trusted Advisor best practices \(checks\)](#).

- CloudWatch home page shows:
 - Current alarms and status
 - Graphs of alarms and resources
 - Service health status

In addition, you can use CloudWatch to do the following:

- Create [customized dashboards](#) to monitor the services that you care about.
- Graph metric data to troubleshoot issues and discover trends.
- Search and browse all your AWS resource metrics.
- Create and edit alarms to be notified of problems.

Viewing instance status and recommendations

Using the Amazon RDS console, you can quickly access the status of your DB instance and respond to Amazon RDS recommendations.

Topics

- [Viewing Amazon RDS DB instance status \(p. 516\)](#)
- [Viewing Amazon RDS recommendations \(p. 520\)](#)

Viewing Amazon RDS DB instance status

The status of a DB instance indicates the health of the DB instance. You can use the following procedures to view the DB instance status in the Amazon RDS console, the AWS CLI command, or the API operation.

Note

Amazon RDS also uses another status called *maintenance status*, which is shown in the **Maintenance** column of the Amazon RDS console. This value indicates the status of any maintenance patches that need to be applied to a DB instance. Maintenance status is independent of DB instance status. For more information about maintenance status, see [Applying updates for a DB instance \(p. 352\)](#).

Find the possible status values for DB instances in the following table. This table also shows whether you will be billed for the DB instance and storage, billed only for storage, or not billed. For all DB instance statuses, you are always billed for backup usage.

DB instance status	Billed	Description
Available	Billed	The DB instance is healthy and available.
Backing-up	Billed	The DB instance is currently being backed up.
Configuring-enhanced-monitoring	Billed	Enhanced Monitoring is being enabled or disabled for this DB instance.
Configuring-iam-database-auth	Billed	AWS Identity and Access Management (IAM) database authentication is being enabled or disabled for this DB instance.
Configuring-log-exports	Billed	Publishing log files to Amazon CloudWatch Logs is being enabled or disabled for this DB instance.
Converting-to-vpc	Billed	The DB instance is being converted from a DB instance that is not in an Amazon Virtual Private Cloud (Amazon VPC) to a DB instance that is in an Amazon VPC.
Creating	Not billed	The DB instance is being created. The DB instance is inaccessible while it is being created.
Deleting	Not billed	The DB instance is being deleted.
Failed	Not billed	The DB instance has failed and Amazon RDS can't recover it. Perform a point-in-time restore to the latest restorable time of the DB instance to recover the data.
Inaccessible-encryption-credentials	Not billed	The AWS KMS key used to encrypt or decrypt the DB instance can't be accessed or recovered.
Inaccessible-encryption-credentials-recoverable	Billed for storage	The KMS key used to encrypt or decrypt the DB instance can't be accessed. However, if the KMS key is active, restarting the DB instance can recover it. For more information, see Encrypting a DB instance (p. 2001) .
Incompatible-network	Not billed	Amazon RDS is attempting to perform a recovery action on a DB instance but can't do so because the VPC is in a state that prevents the action from being completed. This status can occur if, for example, all available IP addresses in a subnet are in use and Amazon RDS can't get an IP address for the DB instance.

DB instance status	Billed	Description
Incompatible-option-group	Billed	Amazon RDS attempted to apply an option group change but can't do so, and Amazon RDS can't roll back to the previous option group state. For more information, check the Recent Events list for the DB instance. This status can occur if, for example, the option group contains an option such as TDE and the DB instance doesn't contain encrypted information.
Incompatible-parameters	Billed	Amazon RDS can't start the DB instance because the parameters specified in the DB instance's DB parameter group aren't compatible with the DB instance. Revert the parameter changes or make them compatible with the DB instance to regain access to your DB instance. For more information about the incompatible parameters, check the Recent Events list for the DB instance.
Incompatible-restore	Not billed	Amazon RDS can't do a point-in-time restore. Common causes for this status include using temp tables, using MyISAM tables with MySQL, or using Aria tables with MariaDB.
Insufficient-capacity	Not billed	Amazon RDS can't create your instance because sufficient capacity isn't currently available. To create your DB instance in the same AZ with the same instance type, delete your DB instance, wait a few hours, and try to create again. Alternatively, create a new instance using a different instance class or AZ.
Maintenance	Billed	Amazon RDS is applying a maintenance update to the DB instance. This status is used for instance-level maintenance that RDS schedules well in advance.
Modifying	Billed	The DB instance is being modified because of a customer request to modify the DB instance.
Moving-to-vpc	Billed	The DB instance is being moved to a new Amazon Virtual Private Cloud (Amazon VPC).
Rebooting	Billed	The DB instance is being rebooted because of a customer request or an Amazon RDS process that requires the rebooting of the DB instance.
Resetting-master-credentials	Billed	The master credentials for the DB instance are being reset because of a customer request to reset them.
Renaming	Billed	The DB instance is being renamed because of a customer request to rename it.
Restore-error	Billed	The DB instance encountered an error attempting to restore to a point-in-time or from a snapshot.
Starting	Billed for storage	The DB instance is starting.
Stopped	Billed for storage	The DB instance is stopped.

DB instance status	Billed	Description
Stopping	Billed for storage	The DB instance is being stopped.
Storage-full	Billed	The DB instance has reached its storage capacity allocation. This is a critical status, and we recommend that you fix this issue immediately. To do so, scale up your storage by modifying the DB instance. To avoid this situation, set Amazon CloudWatch alarms to warn you when storage space is getting low.
Storage-optimization	Billed	Amazon RDS is optimizing the storage of your DB instance. The DB instance is fully operational. The storage optimization process is usually short, but can sometimes take up to and even beyond 24 hours.
Upgrading	Billed	The database engine version is being upgraded.

Console

To view the status of a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

The **Databases page** appears with the list of DB instances. For each DB instance , the status value is displayed.

Databases			
<input type="text"/> Filter by databases			
DB identifier	Role	Status	
database-1	Instance	Stopped	
database-2	Instance	Creating	
database-3	Instance	Available	
database-4	Instance	Configuring-enhanced-monitoring	
database-5	Instance		

CLI

To view DB instance and its status information by using the AWS CLI, use the [describe-db-instances](#) command. For example, the following AWS CLI command lists all the DB instances information .

```
aws rds describe-db-instances
```

To view a specific DB instance and its status, call the [describe-db-instances](#) command with the following option:

- **DBInstanceIdentifier** – The name of the DB instance.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

To view just the status of all the DB instances, use the following query in AWS CLI.

```
aws rds describe-db-instances --query 'DBInstances[*].  
[DBInstanceIdentifier,DBInstanceStatus]' --output table
```

API

To view the status of the DB instance using the Amazon RDS API, call the [DescribeDBInstances](#) operation.

Viewing Amazon RDS recommendations

Amazon RDS provides automated recommendations for database resources, such as DB instances, read replicas, and DB parameter groups. These recommendations provide best practice guidance by analyzing DB instance configuration, usage, and performance data.

You can find examples of these recommendations in the following table.

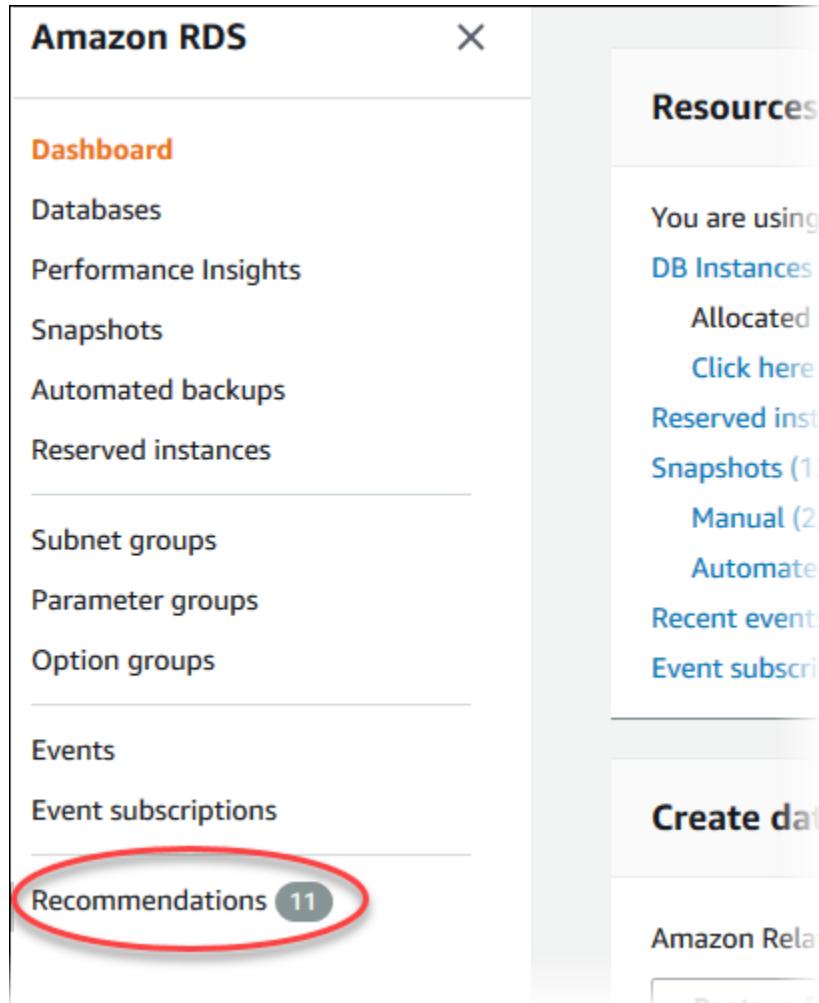

Type	Description	Recommendation	Additional information
Engine version outdated	Your DB instance is not running the latest minor engine version.	We recommend that you upgrade to the latest version because it contains the latest security fixes and other improvements.	Upgrading a DB instance engine version (p. 360)
Pending maintenance available	You have pending maintenance available on your DB instance.	We recommend that you perform the pending maintenance available on your DB instance. Updates to the operating system most often occur for security issues and should be done as soon as possible.	Maintaining a DB instance (p. 350)
Automated backups disabled	Your DB instance has automated backups disabled.	We recommend that you enable automated backups on your DB instance. Automated backups enable point-in-time recovery of your DB instance. You receive backup storage up to the storage size of your DB instance at no additional charge.	Working with backups (p. 427)
Magnetic volumes in use	Your DB instance is using magnetic storage.	Magnetic storage is not recommended for most DB instances. We recommend switching to General Purpose (SSD) storage or provisioned IOPS storage.	Amazon RDS DB instance storage (p. 64)
Enhanced Monitoring disabled	Your DB instance doesn't have Enhanced Monitoring enabled.	We recommend enabling Enhanced Monitoring. Enhanced Monitoring provides real-time operating system metrics for monitoring and troubleshooting.	Monitoring OS metrics with Enhanced Monitoring (p. 600)
Encryption disabled	Your DB instance doesn't have encryption enabled.	We recommend enabling encryption. You can encrypt your existing Amazon RDS DB instances by restoring from an encrypted snapshot.	Encrypting Amazon RDS resources (p. 2000)
Previous generation DB instance class in use	Your DB instance is running on a previous-generation DB instance class.	Previous-generation DB instance classes have been replaced by DB instance classes with better price, better performance, or both. We recommend running your DB instance on a later generation DB instance class.	DB instance classes (p. 10)
Huge pages not used for	The use_large_pages	For increased database scalability, we recommend setting	Turning on HugePages for an

Type	Description	Recommendation	Additional information
an Oracle DB instance	parameter is not set to ONLY in the DB parameter group used by your DB instance.	use_large_pages to ONLY in the DB parameter group used by your DB instance.	RDS for Oracle instance (p. 1610)
Nondefault custom memory parameters	Your DB parameter group sets memory parameters that diverge too much from the default values.	Settings that diverge too much from the default values can cause poor performance and errors. We recommend setting custom memory parameters to their default values in the DB parameter group used by the DB instance.	Working with parameter groups (p. 289)
Change buffering enabled for a MySQL DB instance	Your DB parameter group has change buffering enabled.	Change buffering allows a MySQL DB instance to defer some writes necessary to maintain secondary indexes. This configuration can improve performance slightly, but it can create a large delay in crash recovery. During crash recovery, the secondary index must be brought up to date. So, the benefits of change buffering are outweighed by the potentially very long crash recovery events. We recommend disabling change buffering.	Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog
Query cache enabled for a MySQL DB instance	Your DB parameter group has query cache parameter enabled.	The query cache can cause the DB instance to appear to stall when changes require the cache to be purged. Most workloads don't benefit from a query cache. The query cache was removed from MySQL version 8.0. We recommend that you disable the query cache parameter.	Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog
Logging to table	Your DB parameter group sets logging output to TABLE.	Setting logging output to TABLE uses more storage than setting this parameter to FILE. To avoid reaching the storage limit, we recommend setting the logging output parameter to FILE.	MySQL database log files (p. 700)

Amazon RDS generates recommendations for a resource when the resource is created or modified. Amazon RDS also periodically scans your resources and generates recommendations.

To view Amazon RDS recommendations

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Recommendations**.

The Recommendations page appears.

This screenshot shows the 'Recommendations' page. At the top, there are tabs for Active (2), Dismissed (0), Scheduled (0), and Applied (1). Below the tabs, there are two items listed under the 'Active' tab:

- ▶ Engine version outdated for DB instances (1)
DB instances that are not running the latest minor engine version. [Info](#)
- ▶ Enhanced monitoring disabled (1)
DB instances that don't have Enhanced Monitoring enabled. [Info](#)

3. On the **Recommendations** page, choose one of the following:

- **Active** – Shows the current recommendations that you can apply, dismiss, or schedule.
- **Dismissed** – Shows the recommendations that have been dismissed. When you choose **Dismissed**, you can apply these dismissed recommendations.
- **Scheduled** – Shows the recommendations that are scheduled but not yet applied. These recommendations will be applied in the next scheduled maintenance window.
- **Applied** – Shows the recommendations that are currently applied.

From any list of recommendations, you can open a section to view the recommendations in that section.

Recommendations

Active (2) Dismissed (0) Scheduled (0) Applied (1)

▼ Engine version outdated for DB instances (1)
DB instances that are not running the latest minor engine version. [Info](#)

▶ Enhanced monitoring disabled (1)
DB instances that don't have Enhanced Monitoring enabled. [Info](#)

From the **Preferences** window that appears, you can set display options. These options include the visible columns and the number of recommendations to display on the page.

4. (optional) Respond to your active recommendations as follows:
 - a. Choose **Active** and open one or more sections to view the recommendations in them.
 - b. Choose one or more recommendations and choose **Apply now** (to apply them immediately), **Schedule** (to apply them in next maintenance window), or **Dismiss**.

If the **Apply now** button appears for a recommendation but is unavailable (grayed out), the DB instance is not available. You can apply recommendations immediately only if the DB instance

status is **available**. For example, you can't apply recommendations immediately to the DB instance if its status is **modifying**. In this case, wait for the DB instance to be available and then apply the recommendation.

If the **Apply now** button doesn't appear for a recommendation, you can't apply the recommendation using the **Recommendations** page. You can modify the DB instance to apply the recommendation manually.

For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

Note

When you choose **Apply now**, a brief DB instance outage might result.

Viewing metrics in the Amazon RDS console

Amazon RDS integrates with Amazon CloudWatch to display a variety of RDS DB instance metrics in the RDS console. For descriptions of these metrics, see [Metrics reference for Amazon RDS \(p. 609\)](#).

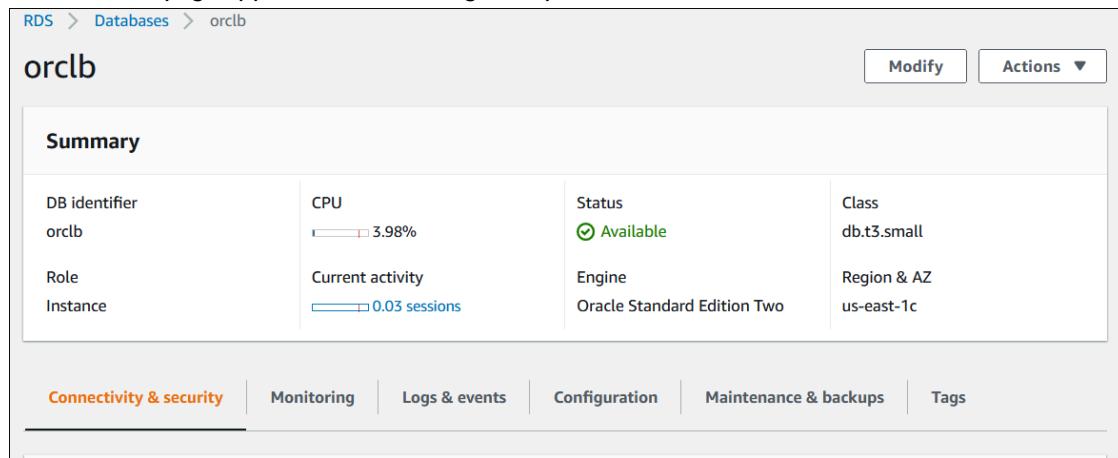

The **Monitoring** tab for your RDS DB instance shows the following categories of metrics:

- **CloudWatch** – Shows the Amazon CloudWatch metrics for that you can access in the RDS console. You can also access these metrics in the CloudWatch console. Each metric includes a graph that shows the metric monitored over a specific time span. For a list of CloudWatch metrics, see [Amazon CloudWatch metrics for Amazon RDS \(p. 609\)](#).
- **Enhanced monitoring** – Shows a summary of operating-system metrics when your RDS DB instance has turned on Enhanced Monitoring. RDS delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. Each OS metric includes a graph showing the metric monitored over a specific time span. For an overview, see [Monitoring OS metrics with Enhanced Monitoring \(p. 600\)](#). For a list of Enhanced Monitoring metrics, see [OS metrics in Enhanced Monitoring \(p. 633\)](#).
- **OS Process list** – Shows details for each process running in your DB instance.
- **Performance Insights** – Opens the Amazon RDS Performance Insights dashboard for a DB instance. For an overview of Performance Insights, see [Monitoring DB load with Performance Insights on Amazon RDS \(p. 543\)](#). For a list of Performance Insights metrics, see [Amazon CloudWatch metrics for Performance Insights \(p. 617\)](#).

To view metrics for your DB instance in the RDS console

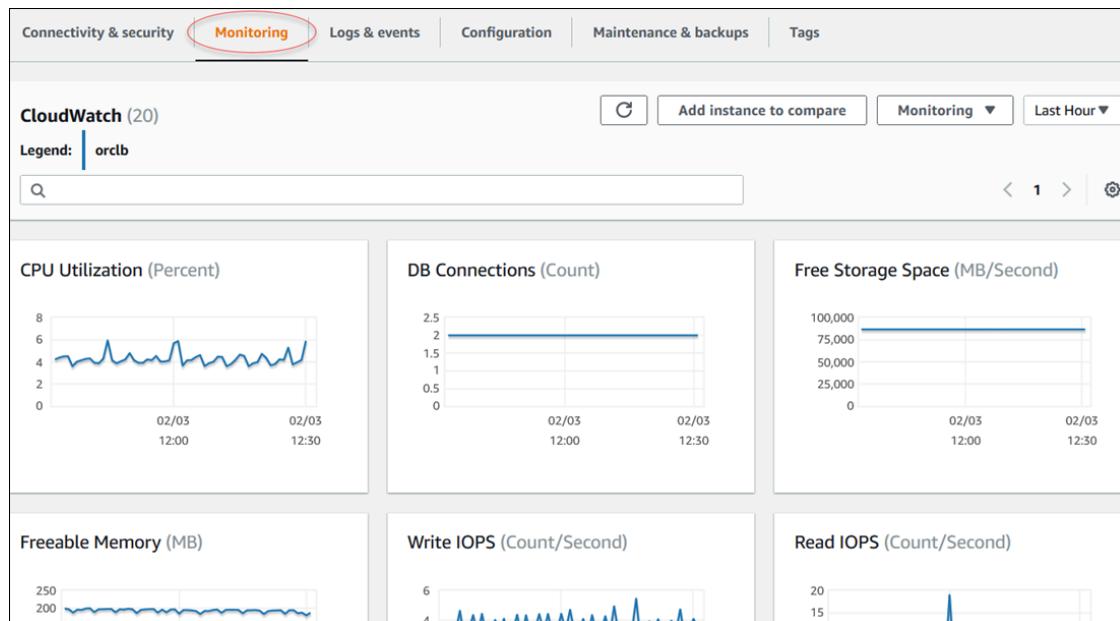

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that you want to monitor.

The database page appears. The following example shows an Oracle database named orclb.

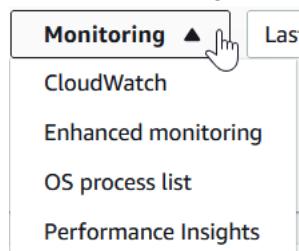

4. Scroll down and choose **Monitoring**.

The monitoring section appears. By default, CloudWatch metrics are shown. For descriptions of these metrics, see [Amazon CloudWatch metrics for Amazon RDS \(p. 609\)](#).

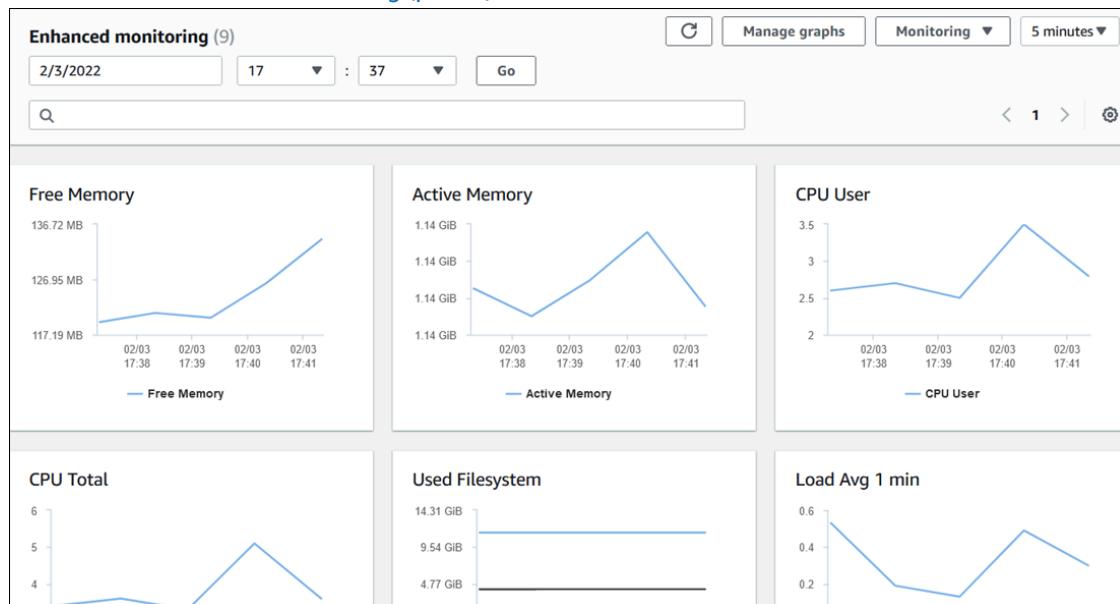

- Choose **Monitoring** to see the metric categories.

- Choose the category of metrics that you want to see.

The following example shows Enhanced Monitoring metrics. For descriptions of these metrics, see [OS metrics in Enhanced Monitoring \(p. 633\)](#).

Tip

To choose the time range of the metrics represented by the graphs, you can use the time range list.

To bring up a more detailed view, you can choose any graph. You can also apply metric-specific filters to the data.

Monitoring Amazon RDS metrics with Amazon CloudWatch

Amazon CloudWatch is a metrics repository. The repository collects and processes raw data from Amazon RDS into readable, near real-time metrics. For a complete list of Amazon RDS metrics sent to CloudWatch, see [Metrics reference for Amazon RDS](#).

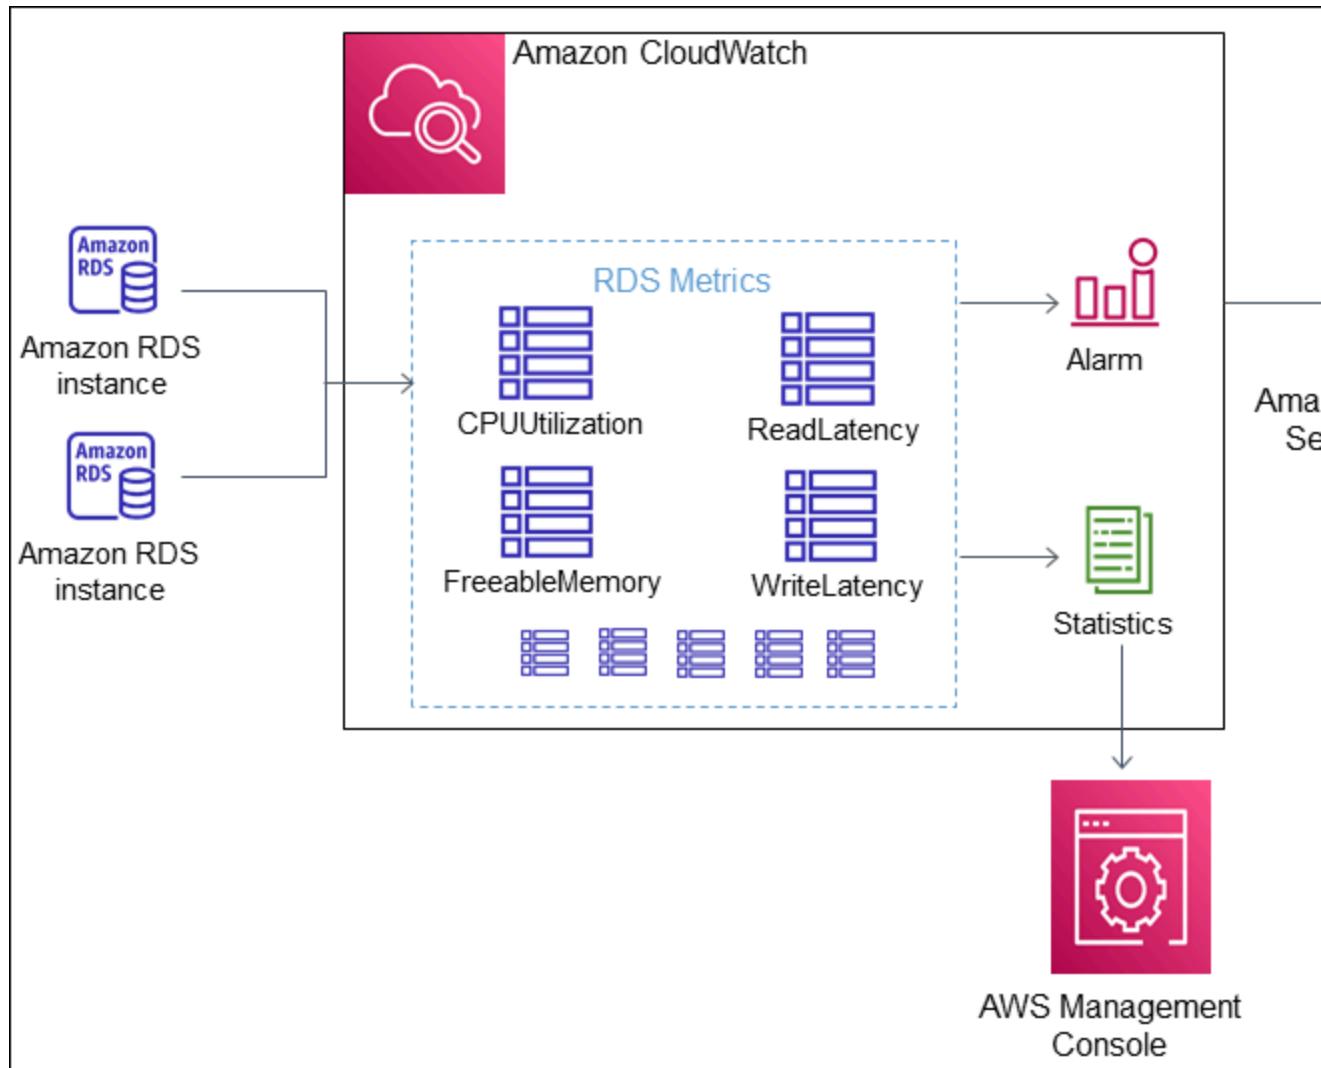

Topics

- [Overview of Amazon RDS and Amazon CloudWatch \(p. 529\)](#)
- [Viewing DB instance metrics in the CloudWatch console and AWS CLI \(p. 530\)](#)
- [Creating CloudWatch alarms to monitor Amazon RDS \(p. 535\)](#)
- [Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag \(p. 536\)](#)

Overview of Amazon RDS and Amazon CloudWatch

By default, Amazon RDS automatically sends metric data to CloudWatch in 1-minute periods. For example, the CPUUtilization metric records the percentage of CPU utilization for a DB instance over time. Data points with a period of 60 seconds (1 minute) are available for 15 days. This means that you can access historical information and see how your web application or service is performing.

As shown in the following diagram, you can set up alarms for your CloudWatch metrics. For example, you might create an alarm that signals when the CPU utilization for an instance is over 70%. You can configure Amazon Simple Notification Service to email you when the threshold is passed.

Amazon RDS publishes the following types of metrics to Amazon CloudWatch:

- Metrics for your RDS DB instances

For a table of these metrics, see [Amazon CloudWatch metrics for Amazon RDS \(p. 609\)](#).

- Performance Insights metrics

For a table of these metrics, see [Amazon CloudWatch metrics for Performance Insights \(p. 617\)](#) and [Performance Insights counter metrics \(p. 618\)](#).

- Enhanced Monitoring metrics (published to Amazon CloudWatch Logs)

For a table of these metrics, see [OS metrics in Enhanced Monitoring \(p. 633\)](#).

- Usage metrics for the Amazon RDS service quotas in your AWS account

For a table of these metrics, see [Amazon CloudWatch usage metrics for Amazon RDS \(p. 615\)](#). For more information about Amazon RDS quotas, see [Quotas and constraints for Amazon RDS \(p. 2135\)](#).

For more information about CloudWatch, see [What is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*. For more information about CloudWatch metrics retention, see [Metrics retention](#).

Viewing DB instance metrics in the CloudWatch console and AWS CLI

Following, you can find details about how to view metrics for your DB instance using CloudWatch. For information on monitoring metrics for your DB instance's operating system in real time using CloudWatch Logs, see [Monitoring OS metrics with Enhanced Monitoring \(p. 600\)](#).

When you use Amazon RDS resources, Amazon RDS sends metrics and dimensions to Amazon CloudWatch every minute. You can use the following procedures to view the metrics for Amazon RDS in the CloudWatch console and CLI.

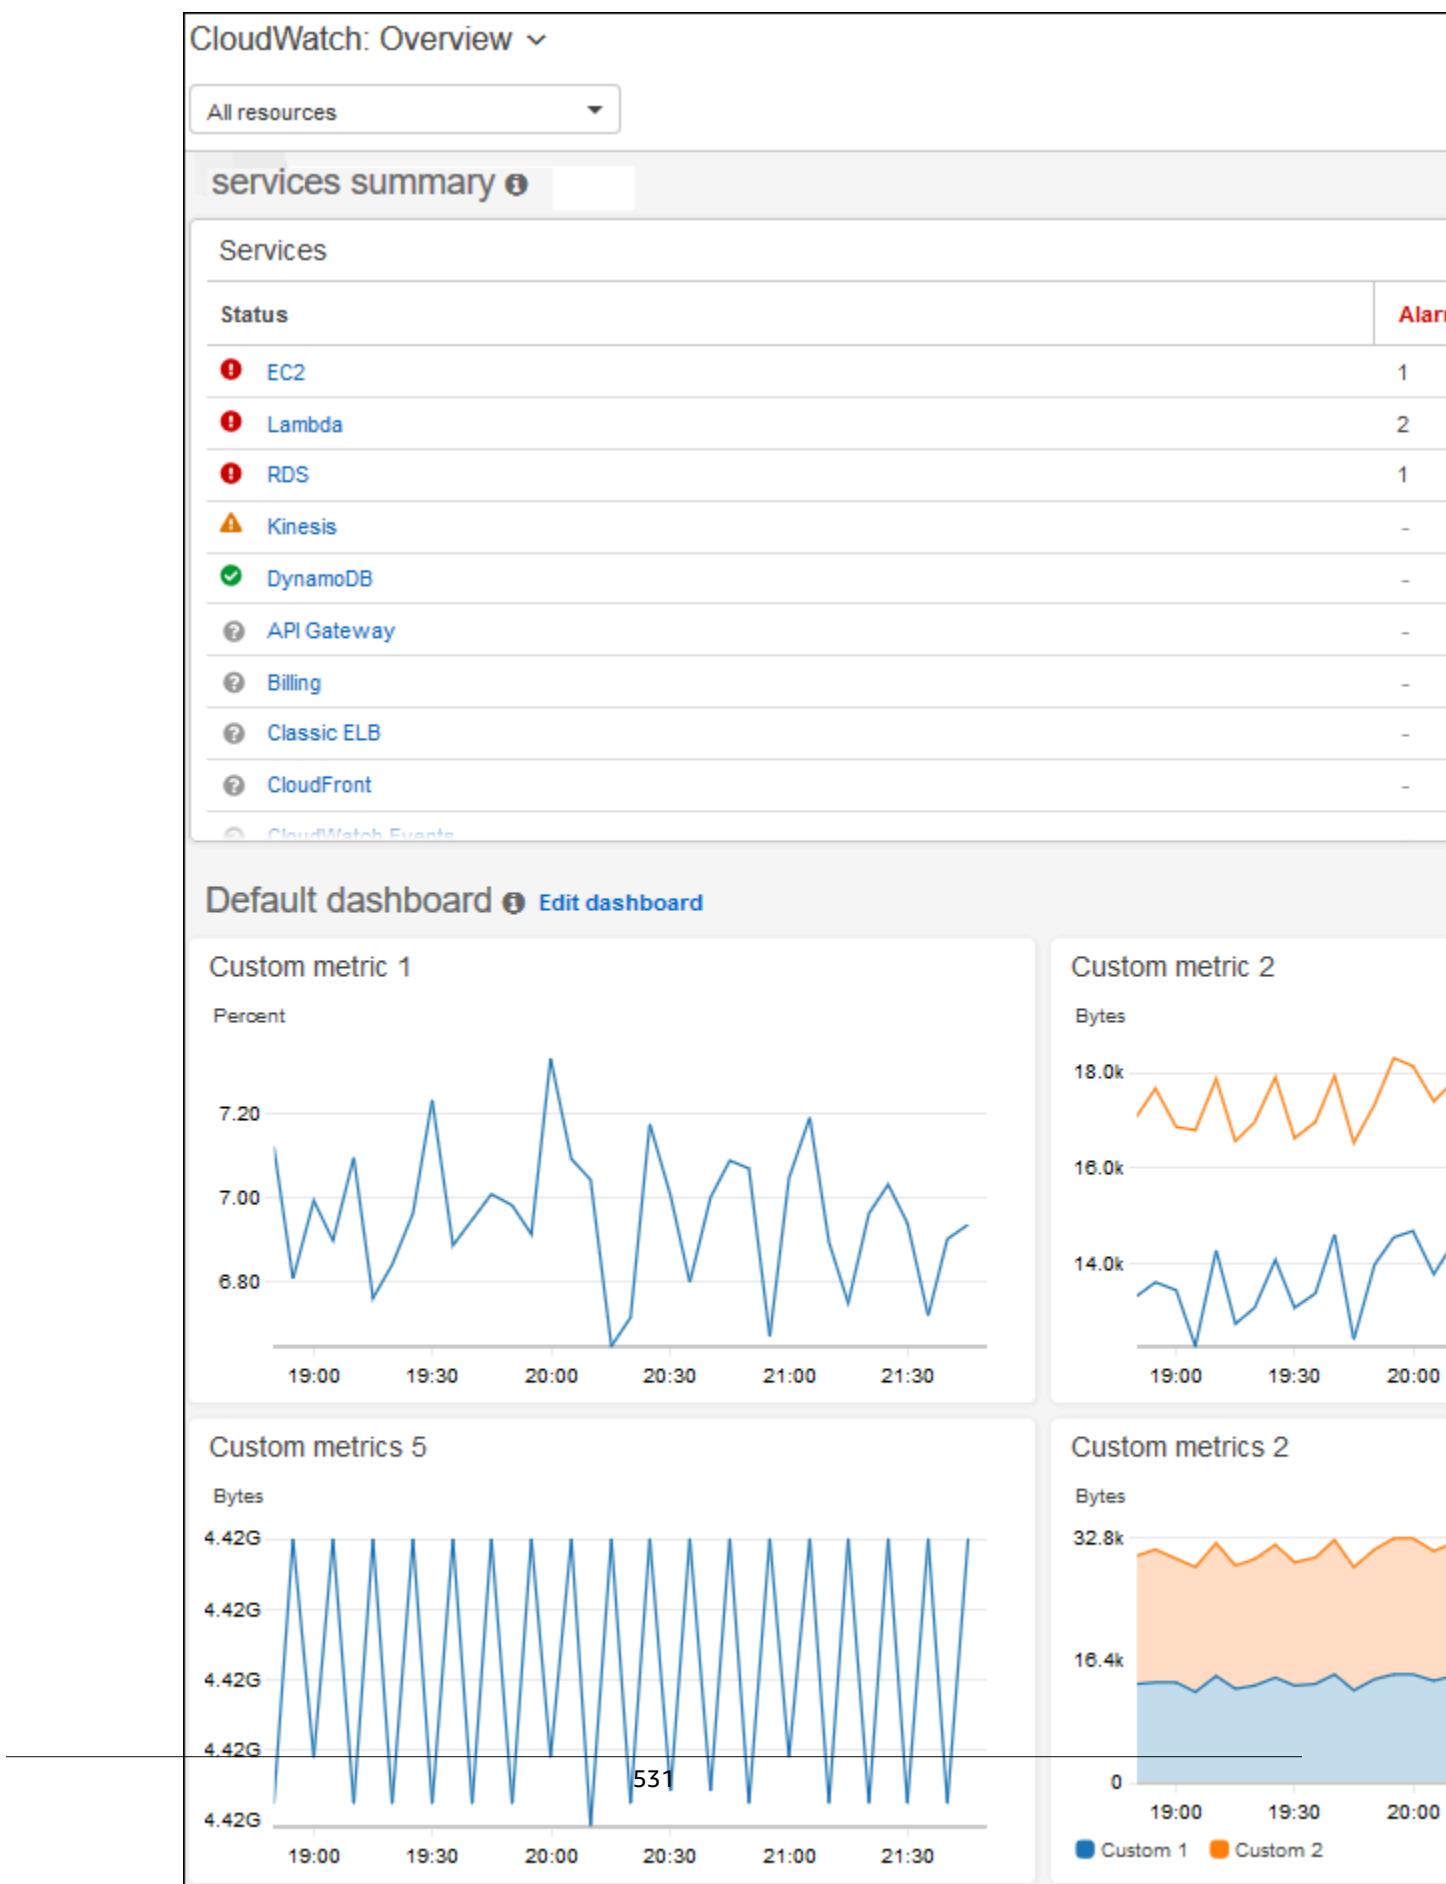

Console

To view metrics using the Amazon CloudWatch console

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.

The CloudWatch overview home page appears.

2. If necessary, change the AWS Region. From the navigation bar, choose the AWS Region where your AWS resources are. For more information, see [Regions and endpoints](#).
3. In the navigation pane, choose **Metrics** and then **All metrics**.

The screenshot shows the 'All metrics' view in the CloudWatch Metrics console. At the top, there are tabs: 'Browse' (which is selected), 'Query', 'Graphed metrics', 'Options', 'Source', and 'Add math'. Below the tabs, it says 'Metrics (1301)' and has a 'Graph with SQL' button. A search bar says 'Search for any metric, dimension or resource id' with a dropdown set to 'N. Virginia'. There are several cards representing different metric namespaces: EBS (9), EC2 (17), Events, Lambda (26), Logs (35), RDS (circled in red), S3 (8), SSM Run Command (3), and Usage.

4. Scroll down and choose the **RDS** metric namespace.

The page displays the Amazon RDS dimensions. For descriptions of these dimensions, see [Amazon CloudWatch dimensions for Amazon RDS \(p. 616\)](#).

The screenshot shows the 'RDS' metric namespace view. At the top, there are tabs: 'Browse' (selected), 'Query', 'Graphed metrics', 'Options', 'Source', and 'Add math'. Below the tabs, it says 'Metrics (1152)' and has a 'Graph with SQL' button. A search bar says 'Search for any metric, dimension or resource id' with a dropdown set to 'N. Virginia'. The path 'All > RDS' is shown. There are several cards representing dimensions: DBClusterIdentifier, Role (153), DbClusterIdentifier, EngineName (6), Per-Database Metrics (332), By Database Class (191), Across All Databases (114), and By Database Engine.

5. Choose a metric dimension, for example **By Database Class**.

Browse Query Graphed metrics (1) Options Source Add math ▾ Add query ▾

Metrics (191) [Info](#)

N. Virginia ▾ All > RDS > By Database Class Search for any metric, dimension or resource id

	Metric name

<input type="checkbox"/>	db.r6g.large ▾
<input type="checkbox"/>	db.r6g.large ▾
<input type="checkbox"/>	db.r6g.large ▾

6. Do any of the following actions:

- To sort the metrics, use the column heading.
- To graph a metric, select the check box next to the metric.
- To filter by resource, choose the resource ID, and then choose **Add to search**.
- To filter by metric, choose the metric name, and then choose **Add to search**.

The following example filters on the **db.t3.medium** class and graphs the **CPUUtilization** metric.

AWS CLI

To obtain metric information by using the AWS CLI, use the CloudWatch command [list-metrics](#). In the following example, you list all metrics in the AWS/RDS namespace.

```
aws cloudwatch list-metrics --namespace AWS/RDS
```

To obtain metric statistics, use the command [get-metric-statistics](#). The following command gets CPUUtilization statistics for instance *my-instance* over the specific 24-hour period, with a 5-minute granularity.

Example

For Linux, macOS, or Unix:

```
aws cloudwatch get-metric-statistics --namespace AWS/RDS \
    --metric-name CPUUtilization \
    --start-time 2021-12-15T00:00:00Z \
    --end-time 2021-12-16T00:00:00Z \
    --period 360 \
    --statistics Minimum \
    --dimensions Name=DBInstanceIdentifier,Value=my-instance
```

For Windows:

```
aws cloudwatch get-metric-statistics --namespace AWS/RDS ^
    --metric-name CPUUtilization ^
    --start-time 2021-12-15T00:00:00Z ^
    --end-time 2021-12-16T00:00:00Z ^
    --period 360 ^
    --statistics Minimum ^
    --dimensions Name=DBInstanceIdentifier,Value=my-instance
```

Sample output appears as follows:

```
{
  "Datapoints": [
    {
      "Timestamp": "2021-12-15T18:00:00Z",
      "Minimum": 8.7,
      "Unit": "Percent"
    },
    {
      "Timestamp": "2021-12-15T23:54:00Z",
      "Minimum": 8.12486458559024,
      "Unit": "Percent"
    },
    {
      "Timestamp": "2021-12-15T17:24:00Z",
      "Minimum": 8.841666666666667,
      "Unit": "Percent"
    },
    ...
    {
      "Timestamp": "2021-12-15T22:48:00Z",
      "Minimum": 8.366248354248954,
      "Unit": "Percent"
    }
  ],
  "Label": "CPUUtilization"
```

}

For more information, see [Getting statistics for a metric](#) in the *Amazon CloudWatch User Guide*.

Creating CloudWatch alarms to monitor Amazon RDS

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period that you specify. The alarm can also perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

Alarms invoke actions for sustained state changes only. CloudWatch alarms don't invoke actions simply because they are in a particular state. The state must have changed and have been maintained for a specified number of time periods. The following procedures show how to create alarms for Amazon RDS.

To set alarms using the CloudWatch console

1. Sign in to the AWS Management Console and open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.

2. Choose **Alarms, All alarms**.

Choose **Create an alarm**.

This action launches a wizard.

3. Choose **Select metric**.

4. In **Browse**, choose **RDS**.

5. Search for the metric that you want to place an alarm on. For example, search for **CPUUtilization**. To display only Amazon RDS metrics, search for the identifier of your resource.

6. Choose the metric to create an alarm on. Then choose **Select metric**.

7. In **Conditions**, define the alarm condition. Then choose **Next**.

For example, you can specify that the alarm should be set when CPU utilization is over 75%.

8. Choose your notification method. Then choose **Next**.

For example, to configure CloudWatch to send you an email when the alarm state is reached, do the following:

1. Choose **Create new topic** (if one doesn't exist).

2. Enter a topic name.

3. Enter the email endpoints.

The email addresses must be verified before they receive notifications. Emails are only sent when the alarm enters an alarm state. If this alarm state change happens before the email addresses are verified, the addresses don't receive a notification.

4. Choose **Create topic**.

5. Choose **Next**.

9. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose **Next**.

10. Preview the alarm that you're about to create. Then choose **Create alarm**.

To set an alarm using the AWS CLI

- Call [put-metric-alarm](#). For more information, see [AWS CLI Command Reference](#).

To set an alarm using the CloudWatch API

- Call [PutMetricAlarm](#). For more information, see [Amazon CloudWatch API Reference](#)

For more information about setting up Amazon SNS topics and creating alarms, see [Using Amazon CloudWatch alarms](#).

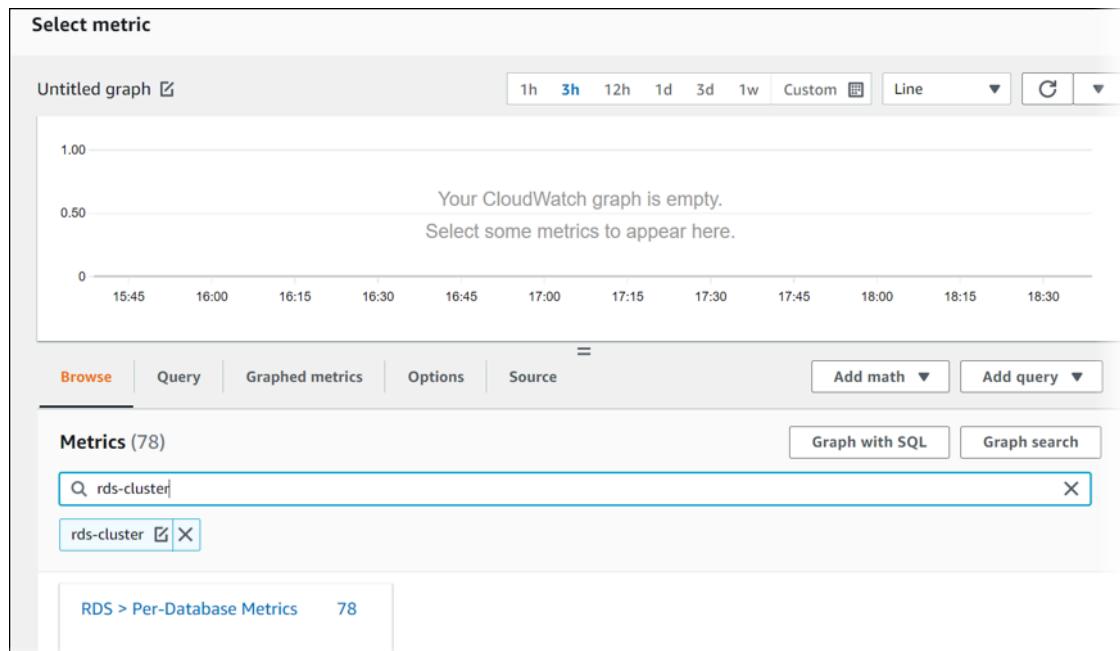

Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag

You can create an Amazon CloudWatch alarm that sends an Amazon SNS message when replica lag for a Multi-AZ DB cluster has exceeded a threshold. An alarm watches the `ReplicaLag` metric over a time period that you specify. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

To set a CloudWatch alarm for Multi-AZ DB cluster replica lag

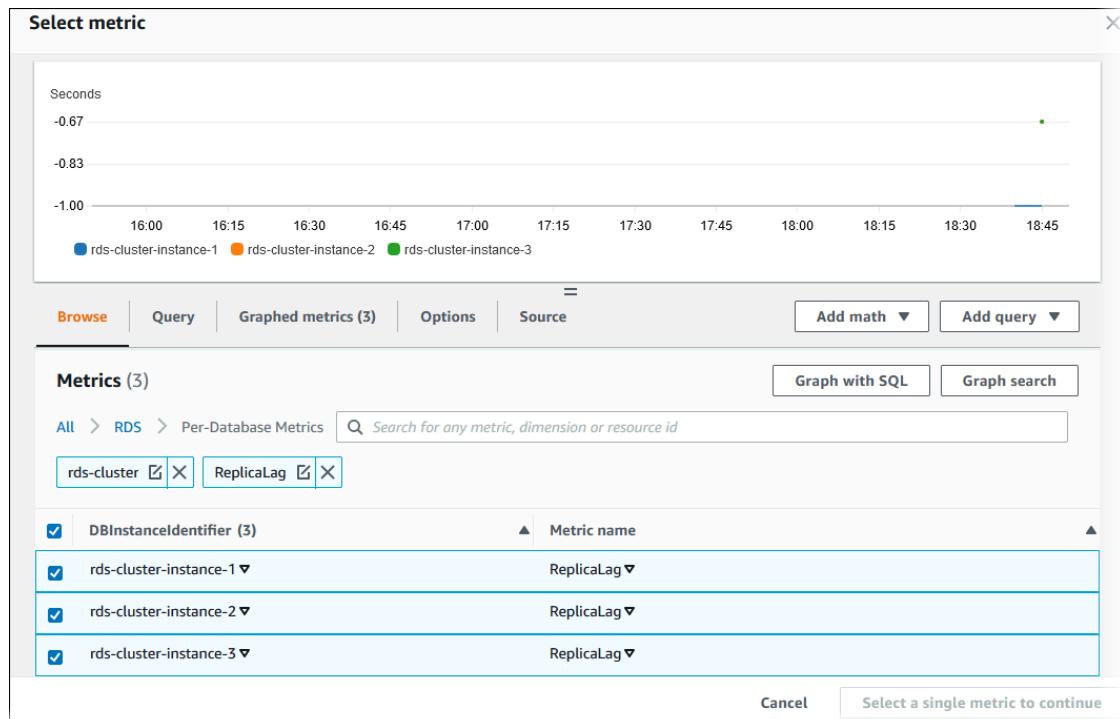

- Sign in to the AWS Management Console and open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
- In the navigation pane, choose **Alarms, All alarms**.
- Choose **Create alarm**.
- On the **Specify metric and conditions** page, choose **Select metric**.
- In the search box, enter the name of your Multi-AZ DB cluster and press Enter.

The following image shows the **Select metric** page with a Multi-AZ DB cluster named `rds-cluster` entered.

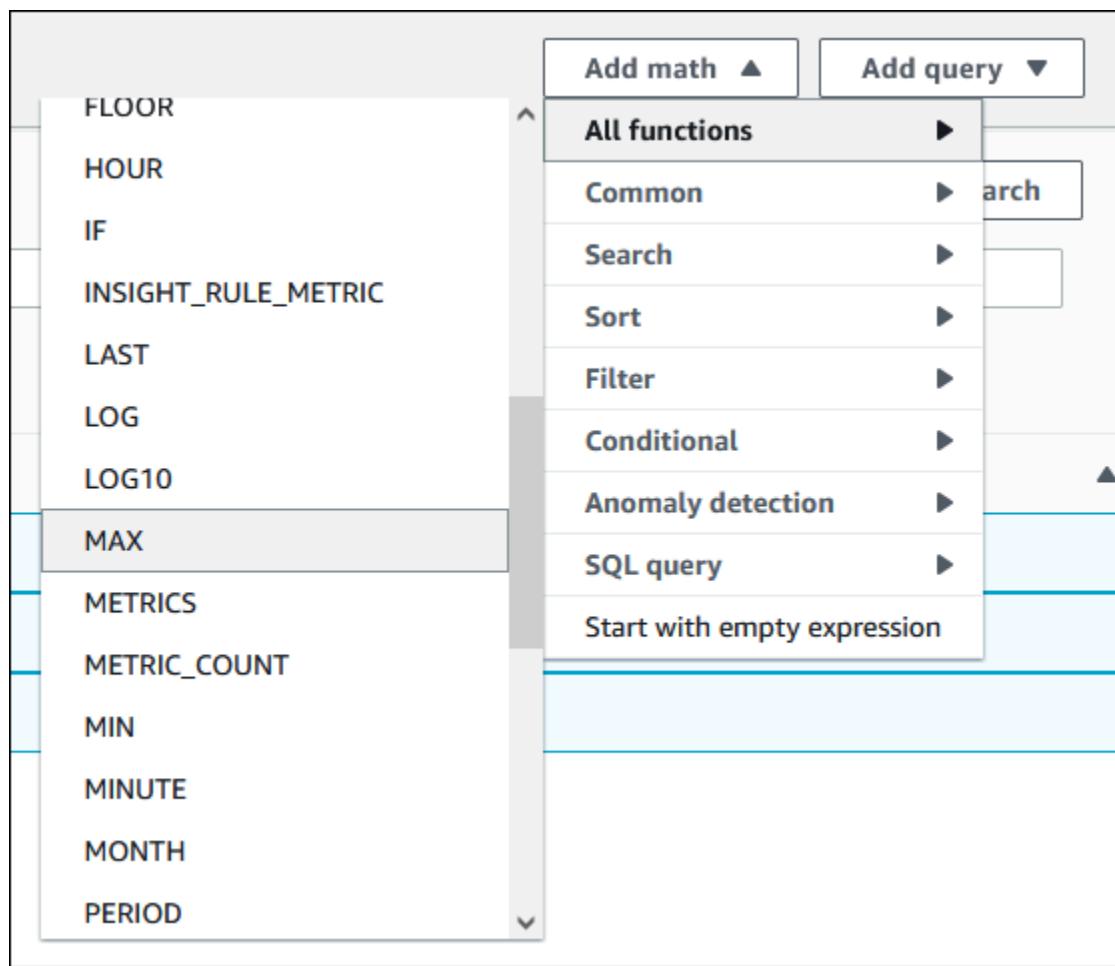

- Choose **RDS, Per-Database Metrics**.
- In the search box, enter **ReplicaLag** and press Enter, then select each DB instance in the DB cluster.

The following image shows the **Select metric** page with the DB instances selected for the `ReplicaLag` metric.

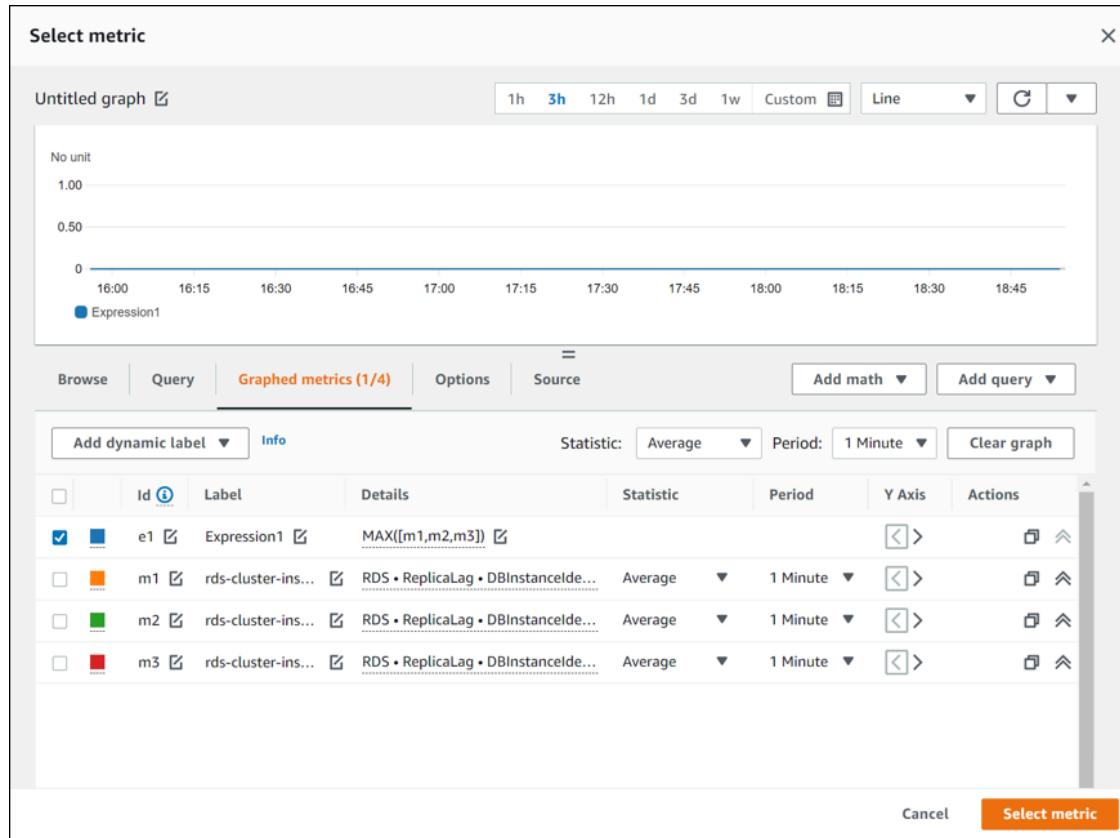

This alarm considers the replica lag for all three of the DB instances in the Multi-AZ DB cluster. The alarm responds when any DB instance exceeds the threshold. It uses a math expression that returns the maximum value of the three metrics. Start by sorting by metric name, and then choose all three **ReplicaLag** metrics.

8. From Add math, choose All functions, MAX.

9. Choose the **Graphed metrics** tab, and edit the details for **Expression1** to **MAX([m1,m2,m3])**.
10. For all three **ReplicaLag** metrics, change the **Period** to **1 minute**.
11. Clear selection from all metrics except for **Expression1**.

The **Select metric** page should look similar to the following image.

12. Choose **Select metric**.
13. On the **Specify metric and conditions** page, change the label to a meaningful name, such as **ClusterReplicaLag**, and enter a number of seconds in **Define the threshold value**. For this tutorial, enter **1200** seconds (20 minutes). You can adjust this value for your workload requirements.

The **Specify metric and conditions** page should look similar to the following image.

Monitoring DB load with Performance Insights on Amazon RDS

Performance Insights expands on existing Amazon RDS monitoring features to illustrate and help you analyze your database performance. With the Performance Insights dashboard, you can visualize the database load on your Amazon RDS DB instance load and filter the load by waits, SQL statements, hosts, or users. For information about using Performance Insights with Amazon DocumentDB, see [Amazon DocumentDB Developer Guide](#).

Topics

- [Overview of Performance Insights on Amazon RDS \(p. 543\)](#)
- [Turning Performance Insights on and off \(p. 549\)](#)
- [Turning on the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL \(p. 553\)](#)
- [Configuring access policies for Performance Insights \(p. 556\)](#)
- [Analyzing metrics with the Performance Insights dashboard \(p. 559\)](#)
- [Retrieving metrics with the Performance Insights API \(p. 584\)](#)
- [Logging Performance Insights calls using AWS CloudTrail \(p. 598\)](#)

Overview of Performance Insights on Amazon RDS

By default, Performance Insights is turned on in the console create wizard for all Amazon RDS engines. If you have more than one database on a DB instance, Performance Insights aggregates performance data.

You can find an overview of Performance Insights for Amazon RDS in the following video.

Using Performance Insights to Analyze Performance of Amazon Aurora PostgreSQL

Important

The following topics describe using Amazon RDS Performance Insights with non-Aurora DB engines. For information about using Amazon RDS Performance Insights with Amazon Aurora, see [Using Amazon RDS Performance Insights](#) in the [Amazon Aurora User Guide](#).

Topics

- [Database load \(p. 543\)](#)
- [Maximum CPU \(p. 547\)](#)
- [Amazon RDS DB engine, Region, and instance class support for Performance Insights \(p. 547\)](#)
- [Pricing and data retention for Performance Insights \(p. 548\)](#)

Database load

Database load (DB load) measures the level of activity in your database. The key metric in Performance Insights is DBLoad, which is collected every second.

Topics

- [Active sessions \(p. 544\)](#)
- [Average active sessions \(p. 544\)](#)
- [Average active executions \(p. 544\)](#)
- [Dimensions \(p. 545\)](#)

Active sessions

A *database session* represents an application's dialogue with a relational database. An *active session* is a connection that has submitted work to the DB engine and is waiting for a response.

A session is active when it's either running on CPU or waiting for a resource to become available so that it can proceed. For example, an active session might wait for a page to be read into memory, and then consume CPU while it reads data from the page.

Average active sessions

The *average active sessions (AAS)* is the unit for the DBLoad metric in Performance Insights. To get the average active sessions, Performance Insights samples the number of sessions concurrently running a query. The AAS is the total number of sessions divided by the total number of samples for a specific time period. The following table shows 5 consecutive samples of a running query.

Sample	Number of sessions running query	AAS	Calculation
1	2	2	2 sessions / 1 sample
2	0	1	2 sessions / 2 samples
3	4	2	6 sessions / 3 samples
4	0	1.5	6 sessions / 4 samples
5	4	2	10 sessions / 5 samples

In the preceding example, the DB load for the time interval was 2 AAS. This measurement means that, on average, 2 sessions were active at a time during the time period when the 5 samples were taken.

An analogy for DB load is activity in a warehouse. Suppose that the warehouse employs 100 workers. If 1 order comes in, 1 worker fulfills the order while the other workers are idle. If 100 orders come in, all 100 workers fulfill orders simultaneously. If you periodically sample how many workers are active over a given time period, you can calculate the average number of active workers. The calculation shows that, on average, N workers are busy fulfilling orders at any given time. If the average was 50 workers yesterday and 75 workers today, the activity level in the warehouse increased. In the same way, DB load increases as session activity increases.

Average active executions

The *average active executions (AAE)* per second is related to AAS. To calculate the AAE, Performance Insights divides the total execution time of a query by the time interval. The following table shows the AAE calculation for the same query in the preceding table.

Elapsed time (sec)	Total execution time (sec)	AAE	Calculation
60	120	2	120 execution seconds/60 elapsed seconds
120	120	1	120 execution seconds/120 elapsed seconds

Elapsed time (sec)	Total execution time (sec)	AAE	Calculation
180	380	2.11	380 execution seconds/180 elapsed seconds
240	380	1.58	380 execution seconds/240 elapsed seconds
300	600	2	600 execution seconds/300 elapsed seconds

In most cases, the AAS and AAE for a query are approximately the same. However, because the inputs to the calculations are different data sources, the calculations often vary slightly.

Dimensions

The db.load metric is different from the other time-series metrics because you can break it into subcomponents called *dimensions*. You can think of dimensions as "slice by" categories for the different characteristics of the DBLoad metric.

When you are diagnosing performance issues, the following dimensions are often the most useful:

Topics

- [Wait events \(p. 545\)](#)
- [Top SQL \(p. 546\)](#)
- [Plans \(p. 546\)](#)

For a complete list of dimensions for the Amazon RDS engines, see [DB load sliced by dimensions \(p. 564\)](#).

Wait events

A *wait event* causes a SQL statement to wait for a specific event to happen before it can continue running. Wait events are an important dimension, or category, for DB load because they indicate where work is impeded.

Every active session is either running on the CPU or waiting. For example, sessions consume CPU when they search memory for a buffer, perform a calculation, or run procedural code. When sessions aren't consuming CPU, they might be waiting for a memory buffer to become free, a data file to be read, or a log to be written to. The more time that a session waits for resources, the less time it runs on the CPU.

When you tune a database, you often try to find out the resources that sessions are waiting for. For example, two or three wait events might account for 90 percent of DB load. This measure means that, on average, active sessions are spending most of their time waiting for a small number of resources. If you can find out the cause of these waits, you can attempt a solution.

Consider the analogy of a warehouse worker. An order comes in for a book. The worker might be delayed in fulfilling the order. For example, a different worker might be currently restocking the shelves, a trolley might not be available. Or the system used to enter the order status might be slow. The longer the worker waits, the longer it takes to fulfill the order. Waiting is a natural part of the warehouse workflow, but if wait time becomes excessive, productivity decreases. In the same way, repeated or lengthy session

waits can degrade database performance. For more information, see [Tuning with wait events for Aurora PostgreSQL](#) and [Tuning with wait events for Aurora MySQL](#) in the *Amazon Aurora User Guide*.

Wait events vary by DB engine:

- For information about all MariaDB and MySQL wait events, see [Wait Event Summary Tables](#) in the MySQL documentation.
- For information about all PostgreSQL wait events, see [The Statistics Collector > Wait Event tables](#) in the PostgreSQL documentation.
- For information about all Oracle wait events, see [Descriptions of Wait Events](#) in the Oracle documentation.
- For information about all SQL Server wait events, see [Types of Waits](#) in the SQL Server documentation.

Note

For Oracle, background processes sometimes do work without an associated SQL statement. In these cases, Performance Insights reports the type of background process concatenated with a colon and the wait class associated with that background process. Types of background process include LGWR, ARC0, PMON, and so on.

For example, when the archiver is performing I/O, the Performance Insights report for it is similar to ARC1: System I/O. Occasionally, the background process type is also missing, and Performance Insights only reports the wait class, for example :System I/O.

Top SQL

Where wait events show bottlenecks, top SQL shows which queries are contributing the most to DB load. For example, many queries might be currently running on the database, but a single query might consume 99 percent of the DB load. In this case, the high load might indicate a problem with the query.

By default, the Performance Insights console displays top SQL queries that are contributing to the database load. The console also shows relevant statistics for each statement. To diagnose performance problems for a specific statement, you can examine its execution plan.

Plans

An *execution plan*, also called simply a *plan*, is a sequence of steps that access data. For example, a plan for joining tables t1 and t2 might loop through all rows in t1 and compare each row to a row in t2. In a relational database, an *optimizer* is built-in code that determines the most efficient plan for a SQL query.

For Oracle DB instances, Performance Insights collects execution plans automatically. To diagnose SQL performance problems, examine the captured plans for high-resource Oracle SQL queries. The plans show how Oracle Database has parsed and run queries.

To learn how to analyze DB load using plans, see [Analyzing Oracle execution plans using the Performance Insights dashboard \(p. 581\)](#).

Plan capture

Every five minutes, Performance Insights identifies the most resource-intensive Oracle queries and captures their plans. Thus, you don't need to manually collect and manage a huge number of plans. Instead, you can use the **Top SQL** tab to focus on the plans for the most problematic queries.

Note

Performance Insights doesn't capture plans for queries whose text exceeds the maximum collectable query text limit. For more information, see [Accessing more SQL text in the Performance Insights dashboard \(p. 576\)](#).

The retention period for execution plans is the same as for your Performance Insights data. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see [Pricing and data retention for Performance Insights \(p. 548\)](#).

Digest queries

The **Top SQL** tab shows digest queries by default. A digest query doesn't itself have a plan, but all queries that use literal values have plans. For example, a digest query might include the text WHERE `email`=? . The digest might contain two queries, one with the text WHERE email=user1@example.com and another with WHERE email=user2@example.com . Each of these literal queries might include multiple plans.

If you select a digest query, the console shows all plans for child statements of the selected digest. Thus, you don't need to look through all the child statements to find the plan. You might see plans that aren't in the displayed list of top 10 child statements. The console shows plans for all child queries for which plans have been collected, regardless of whether the queries are in the top 10.

Maximum CPU

In the dashboard, the **Database load** chart collects, aggregates, and displays session information. To see whether active sessions are exceeding the maximum CPU, look at their relationship to the **Max vCPU** line. The **Max vCPU** value is determined by the number of vCPU (virtual CPU) cores for your DB instance.

One process can run on a vCPU at a time. If the number of processes exceed the number of vCPUs, the processes start queuing. When the queuing increase, the performance is impacted. If the DB load is often above the **Max vCPU** line, and the primary wait state is CPU, the CPU is overloaded. In this case, you might want to throttle connections to the instance, tune any SQL queries with a high CPU load, or consider a larger instance class. High and consistent instances of any wait state indicate that there might be bottlenecks or resource contention issues to resolve. This can be true even if the DB load doesn't cross the **Max vCPU** line.

Amazon RDS DB engine, Region, and instance class support for Performance Insights

Following, you can find the Amazon RDS DB engines that support Performance Insights.

Note

For Amazon Aurora, see [Amazon Aurora DB engine support for Performance Insights in Amazon Aurora User Guide](#).

Amazon RDS DB engine	Supported engine versions and Regions	Instance class restrictions
Amazon RDS for MariaDB	For more information on version and Region availability of Performance Insights with RDS for MariaDB, see Performance Insights (p. 110) .	Performance Insights isn't supported for the following instance classes: <ul style="list-style-type: none">• db.t2.micro• db.t2.small• db.t3.micro• db.t3.small The db.t4g.micro and db.t4g.small instance classes require 10.6 and higher.

Amazon RDS DB engine	Supported engine versions and Regions	Instance class restrictions
RDS for MySQL	For more information on version and Region availability of Performance Insights with RDS for MySQL, see Performance Insights (p. 110) .	Performance Insights isn't supported for the following instance classes: <ul style="list-style-type: none"> • db.t2.micro • db.t2.small • db.t3.micro • db.t3.small The db.t4g instance classes require 8.0.25 and higher version 8.
Amazon RDS for Microsoft SQL Server	For more information on version and Region availability of Performance Insights with RDS for SQL Server, see Performance Insights (p. 110) .	N/A
Amazon RDS for PostgreSQL	For more information on version and Region availability of Performance Insights with RDS for PostgreSQL, see Performance Insights (p. 110) .	N/A
Amazon RDS for Oracle	For more information on version and Region availability of Performance Insights with RDS for Oracle, see Performance Insights (p. 110) .	N/A

Pricing and data retention for Performance Insights

By default, Performance Insights offers a free tier that includes 7 days of performance data history and 1 million API requests per month. You can also purchase longer retention periods. For complete pricing information, see [Performance Insights Pricing](#).

In the RDS console, you can choose any of the following retention periods for your Performance Insights data:

- **Default (7 days)**
- ***n* months**, where *n* is a number from 1–24

Performance Insights [Info](#)

Turn on Performance Insights [Info](#)

To learn how to set a retention period using the AWS CLI, see [AWS CLI \(p. 551\)](#).

Turning Performance Insights on and off

You can turn on Performance Insights for your DB instance or Multi-AZ DB cluster when you create it. If needed, you can turn it off later. Turning Performance Insights on and off doesn't cause downtime, a reboot, or a failover.

Note

Performance Schema is an optional performance tool used by Amazon RDS for MariaDB or MySQL. If you turn Performance Schema on or off, you need to reboot. If you turn Performance Insights on or off, however, you don't need to reboot. For more information, see [Turning on the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL \(p. 553\)](#).

The Performance Insights agent consumes limited CPU and memory on the DB host. When the DB load is high, the agent limits the performance impact by collecting data less frequently.

Console

In the console, you can turn Performance Insights on or off when you create or modify a DB instance or Multi-AZ DB cluster.

Turning Performance Insights on or off when creating a DB instance or Multi-AZ DB cluster

When you create a new DB instance or Multi-AZ DB cluster, turn on Performance Insights by choosing **Enable Performance Insights** in the **Performance Insights** section. Or choose **Disable Performance Insights**. For more information, see the following topics:

- To create a DB instance, follow the instructions for your DB engine in [Creating an Amazon RDS DB instance \(p. 230\)](#).
- To create a Multi-AZ DB cluster, follow the instructions for your DB engine in [Creating a Multi-AZ DB cluster \(p. 252\)](#).

The following screenshot shows the **Performance Insights** section.

If you choose **Enable Performance Insights**, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see [Pricing and data retention for Performance Insights \(p. 548\)](#).
- **AWS KMS key** – Specify your AWS KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see [Configuring an AWS KMS policy for Performance Insights \(p. 558\)](#).

Turning Performance Insights on or off when modifying a DB instance or Multi-AZ DB cluster

In the console, you can modify a DB instance or Multi-AZ DB cluster to turn Performance Insights on or off.

To turn Performance Insights on or off for a DB instance or Multi-AZ DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases**.
3. Choose a DB instance or Multi-AZ DB cluster, and choose **Modify**.
4. In the **Performance Insights** section, choose either **Enable Performance Insights** or **Disable Performance Insights**.

If you choose **Enable Performance Insights**, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see [Pricing and data retention for Performance Insights \(p. 548\)](#).
 - **AWS KMS key** – Specify your KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see [Encrypting Amazon RDS resources \(p. 2000\)](#).
5. Choose **Continue**.
 6. For **Scheduling of Modifications**, choose **Apply immediately**. If you choose **Apply during the next scheduled maintenance window**, your instance ignores this setting and turns on Performance Insights immediately.
 7. Choose **Modify instance**.

AWS CLI

When you use the [create-db-instance](#) AWS CLI command, turn on Performance Insights by specifying `--enable-performance-insights`. Or turn off Performance Insights by specifying `--no-enable-performance-insights`.

You can also specify these values using the following AWS CLI commands:

- [create-db-instance-read-replica](#)
- [modify-db-instance](#)
- [restore-db-instance-from-s3](#)
- [create-db-cluster](#) (Multi-AZ DB cluster)
- [modify-db-cluster](#) (Multi-AZ DB cluster)

The following procedure describes how to turn Performance Insights on or off for an existing DB instance using the AWS CLI.

To turn Performance Insights on or off for a DB instance using the AWS CLI

- Call the [modify-db-instance](#) AWS CLI command and supply the following values:
 - `--db-instance-identifier` – The name of the DB instance.
 - `--enable-performance-insights` to turn on or `--no-enable-performance-insights` to turn off

The following example turns on Performance Insights for `sample-db-instance`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier sample-db-instance \
  --enable-performance-insights
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier sample-db-instance ^
```

```
--enable-performance-insights
```

When you turn on Performance Insights in the CLI, you can optionally specify the number of days to retain Performance Insights data with the `--performance-insights-retention-period` option. You can specify 7, *month* * 31 (where *month* is a number from 1–23), or 731. For example, if you want to retain your performance data for 3 months, specify 93, which is 3 * 31. The default is 7 days. For more information about retention periods, see [Pricing and data retention for Performance Insights \(p. 548\)](#).

The following example turns on Performance Insights for `sample-db-instance` and specifies that Performance Insights data is retained for 93 days (3 months).

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier sample-db-instance \
  --enable-performance-insights \
  --performance-insights-retention-period 93
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier sample-db-instance ^
  --enable-performance-insights ^
  --performance-insights-retention-period 93
```

If you specify a retention period such as 94 days, which isn't a valid value, RDS issues an error.

```
An error occurred (InvalidParameterValue) when calling the CreateDBInstance operation:
Invalid Performance Insights retention period. Valid values are: [7, 31, 62, 93, 124, 155,
186, 217,
248, 279, 310, 341, 372, 403, 434, 465, 496, 527, 558, 589, 620, 651, 682, 713, 731]
```

RDS API

When you create a new DB instance using the [CreateDBInstance](#) operation Amazon RDS API operation, turn on Performance Insights by setting `EnablePerformanceInsights` to `True`. To turn off Performance Insights, set `EnablePerformanceInsights` to `False`.

You can also specify the `EnablePerformanceInsights` value using the following API operations:

- [ModifyDBInstance](#)
- [CreateDBInstanceReadReplica](#)
- [RestoreDBInstanceFromS3](#)
- [CreateDBCluster](#) (Multi-AZ DB cluster)
- [ModifyDBCluster](#) (Multi-AZ DB cluster)

When you turn on Performance Insights, you can optionally specify the amount of time, in days, to retain Performance Insights data with the `PerformanceInsightsRetentionPeriod` parameter. You can specify 7, *month* * 31 (where *month* is a number from 1–23), or 731. For example, if you want to retain your performance data for 3 months, specify 93, which is 3 * 31. The default is 7 days. For more information about retention periods, see [Pricing and data retention for Performance Insights \(p. 548\)](#).

Turning on the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL

The Performance Schema is an optional feature for monitoring Amazon RDS for MariaDB or MySQL runtime performance at a low level of detail. The Performance Schema is designed to have minimal impact on database performance. Performance Insights is a separate feature that you can use with or without the Performance Schema.

Topics

- [Overview of the Performance Schema \(p. 553\)](#)
- [Performance Insights and the Performance Schema \(p. 553\)](#)
- [Automatic management of the Performance Schema by Performance Insights \(p. 554\)](#)
- [Effect of a reboot on the Performance Schema \(p. 554\)](#)
- [Determining whether Performance Insights is managing the Performance Schema \(p. 555\)](#)
- [Configuring the Performance Schema for automatic management \(p. 555\)](#)

Overview of the Performance Schema

The Performance Schema monitors events in MariaDB and MySQL databases. An *event* is a database server action that consumes time and has been instrumented so that timing information can be collected. Examples of events include the following:

- Function calls
- Waits for the operating system
- Stages of SQL execution
- Groups of SQL statements

The PERFORMANCE_SCHEMA storage engine is a mechanism for implementing the Performance Schema feature. This engine collects event data using instrumentation in the database source code. The engine stores events in memory-only tables in the performance_schema database. You can query performance_schema just as you can query any other tables. For more information, see [MySQL Performance Schema](#) in the *MySQL Reference Manual*.

Performance Insights and the Performance Schema

Performance Insights and the Performance Schema are separate features, but they are connected. The behavior of Performance Insights for Amazon RDS for MariaDB or MySQL depends on whether the Performance Schema is turned on, and if so, whether Performance Insights manages the Performance Schema automatically. The following table describes the behavior.

Performance Schema turned on	Performance Insights management mode	Performance Insights behavior
Yes	Automatic	<ul style="list-style-type: none">• Collects detailed, low-level monitoring information• Collects active session metrics every second• Displays DB load categorized by detailed wait events, which you can use to identify bottlenecks
Yes	Manual	<ul style="list-style-type: none">• Collects wait events and per-SQL metrics

Performance Schema turned on	Performance Insights management mode	Performance Insights behavior
		<ul style="list-style-type: none"> Collects active session metrics every five seconds instead of every second Reports user states such as inserting and sending, which don't help you identify bottlenecks
No	N/A	<ul style="list-style-type: none"> Doesn't collect wait events, per-SQL metrics, or other detailed, low-level monitoring information Collects active session metrics every five seconds instead of every second Reports user states such as inserting and sending, which don't help you identify bottlenecks

Automatic management of the Performance Schema by Performance Insights

When you create an Amazon RDS for MariaDB or MySQL DB instance with Performance Insights turned on, the Performance Schema is also turned on. In this case, Performance Insights automatically manages your Performance Schema parameters. This is the recommended configuration.

Note

Automatic management of the Performance Schema isn't supported for the t4g.medium instance class.

For automatic management of the Performance Schema, the following conditions must be true:

- The `performance_schema` parameter is set to `0`.
- The **Source** is set to `system`, which is the default.

If you change the `performance_schema` parameter value manually, and then later want to change to automatic management, see [Configuring the Performance Schema for automatic management \(p. 555\)](#).

Important

When Performance Insights turns on the Performance Schema, it doesn't change the parameter group values. However, the values are changed on the DB instances that are running. The only way to see the changed values is to run the `SHOW GLOBAL VARIABLES` command.

Effect of a reboot on the Performance Schema

Performance Insights and the Performance Schema differ in their requirements for DB instance reboots:

Performance Schema

To turn this feature on or off, you must reboot the DB instance.

Performance Insights

To turn this feature on or off, you don't need to reboot the DB instance.

If the Performance Schema isn't currently turned on, and you turn on Performance Insights without rebooting the DB instance, the Performance Schema won't be turned on.

Determining whether Performance Insights is managing the Performance Schema

To find out whether Performance Insights is currently managing the Performance Schema for major engine versions 5.6, 5.7, and 8.0, review the following table.

Setting of performance_schema parameter	Setting of the Source column	Performance Insights is managing the Performance Schema?
0	system	Yes
0 or 1	user	No

To determine whether Performance Insights is managing the Performance Schema automatically

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Parameter groups**.
3. Select the name of the parameter group for your DB instance.
4. Enter **performance_schema** in the search bar.
5. Check whether **Source** is the system default and **Values** is **0**. If so, Performance Insights is managing the Performance Schema automatically. If not, Performance Insights isn't managing the Performance Schema automatically.

The screenshot shows the 'Parameters' section of the AWS RDS Parameter Groups configuration. A search bar at the top contains 'performance_schema'. Below it, a table lists parameters. The 'performance_schema' parameter is selected, showing its current value as '0' in the 'Values' dropdown, which is highlighted with a red box. The 'Source' dropdown also has a red box around its value 'user'.

Name	Values	Allowed values	Modifiable	Source
performance_schema	0	0, 1	true	user

Configuring the Performance Schema for automatic management

Assume that Performance Insights is turned on for your DB instance or Multi-AZ DB cluster but isn't currently managing the Performance Schema. If you want to allow Performance Insights to manage the Performance Schema automatically, complete the following steps.

To configure the Performance Schema for automatic management

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Parameter groups**.
3. Select the name of the parameter group for your DB instance or Multi-AZ DB cluster.
4. Enter **performance_schema** in the search bar.
5. Select the **performance_schema** parameter.
6. Choose **Edit parameters**.
7. Select the **performance_schema** parameter.

8. In **Values**, choose **0**.
9. Choose **Reset** and then **Reset parameters**.
10. Reboot the DB instance or Multi-AZ DB cluster.

Important

Whenever you turn the Performance Schema on or off, make sure to reboot the DB instance or Multi-AZ DB cluster.

For more information about modifying instance parameters, see [Modifying parameters in a DB parameter group \(p. 294\)](#). For more information about the dashboard, see [Analyzing metrics with the Performance Insights dashboard \(p. 559\)](#). For more information about the MySQL performance schema, see [MySQL 8.0 Reference Manual](#).

Configuring access policies for Performance Insights

To access Performance Insights, a principal must have the appropriate permissions from AWS Identity and Access Management (IAM). You can grant access in the following ways:

- Attach the `AmazonRDSPerformanceInsightsReadOnly` managed policy to an IAM user or role.
- Create a custom IAM policy and attach it to an IAM user or role.

If you specified a customer managed key when you turned on Performance Insights, make sure that users in your account have the `kms:Decrypt` and `kms:GenerateDataKey` permissions on the KMS key.

Attaching the `AmazonRDSPerformanceInsightsReadOnly` policy to an IAM principal

`AmazonRDSPerformanceInsightsReadOnly` is an AWS-managed policy that grants access to all read-only operations of the Amazon RDS Performance Insights API. Currently, all operations in this API are read-only.

If you attach `AmazonRDSPerformanceInsightsReadOnly` to an IAM user or role, the recipient can use Performance Insights with other console features.

Creating a custom IAM policy for Performance Insights

For users who don't have the `AmazonRDSPerformanceInsightsReadOnly` policy, you can grant access to Performance Insights by creating or modifying a user-managed IAM policy. When you attach the policy to an IAM user or role, the recipient can use Performance Insights.

To create a custom policy

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Create Policy** page, choose the **JSON** tab.
5. Copy and paste the following text, replacing `us-east-1` with the name of your AWS Region and `111122223333` with your customer account number.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "rds:DescribePerformanceInsights",  
            "Resource": "arn:aws:rds:us-east-1:111122223333:*:performance-insights/*"  
        }  
    ]  
}
```

```

        "Action": "rds:DescribeDBInstances",
        "Resource": "*"
    },
    {
        "Effect": "Allow",
        "Action": "rds:DescribeDBClusters",
        "Resource": "*"
    },
    {
        "Effect": "Allow",
        "Action": "pi:DescribeDimensionKeys",
        "Resource": "arn:aws:pi:us-east-1:111122223333:metrics/rds/*"
    },
    {
        "Effect": "Allow",
        "Action": "pi:GetDimensionKeyDetails",
        "Resource": "arn:aws:pi:us-east-1:111122223333:metrics/rds/*"
    },
    {
        "Effect": "Allow",
        "Action": "pi:GetResourceMetadata",
        "Resource": "arn:aws:pi:us-east-1:111122223333:metrics/rds/*"
    },
    {
        "Effect": "Allow",
        "Action": "pi:GetResourceMetrics",
        "Resource": "arn:aws:pi:us-east-1:111122223333:metrics/rds/*"
    },
    {
        "Effect": "Allow",
        "Action": "pi>ListAvailableResourceDimensions",
        "Resource": "arn:aws:pi:us-east-1:111122223333:metrics/rds/*"
    },
    {
        "Effect": "Allow",
        "Action": "pi>ListAvailableResourceMetrics",
        "Resource": "arn:aws:pi:us-east-1:111122223333:metrics/rds/*"
    }
]
}

```

6. Choose **Review policy**.
7. Provide a name for the policy and optionally a description, and then choose **Create policy**.

You can now attach the policy to an IAM user or role. The following procedure assumes that you already have an IAM user available for this purpose.

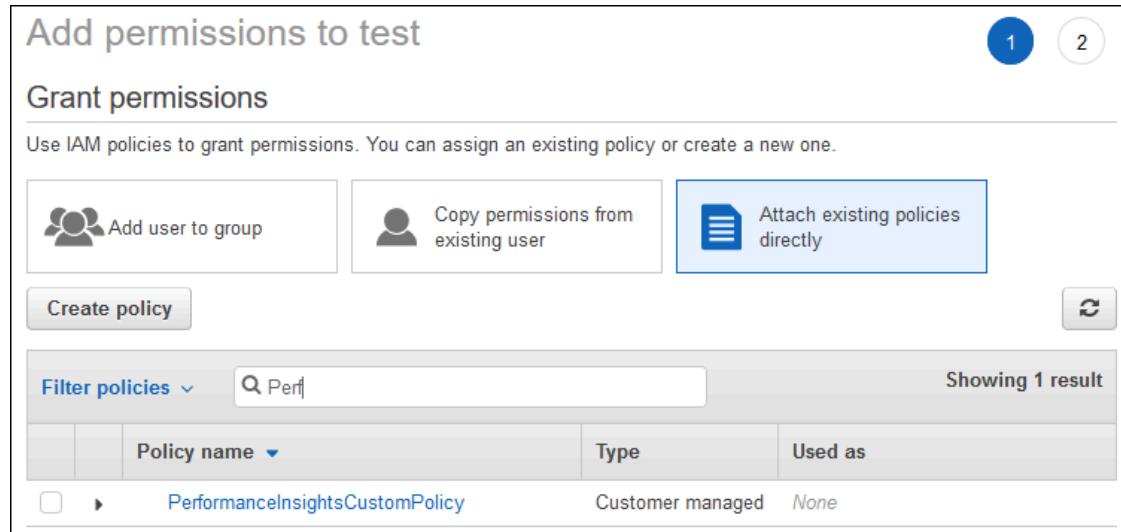

To attach the policy to an IAM user

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose an existing user from the list.

Important

To use Performance Insights, make sure that you have access to Amazon RDS in addition to the custom policy. For example, the `AmazonRDSPerformanceInsightsReadOnly` predefined policy provides read-only access to Amazon RDS. For more information, see [Managing access using policies \(p. 2018\)](#).

4. On the **Summary** page, choose **Add permissions**.
5. Choose **Attach existing policies directly**. For **Search**, type the first few characters of your policy name, as shown following.

6. Choose your policy, and then choose **Next: Review**.
7. Choose **Add permissions**.

Configuring an AWS KMS policy for Performance Insights

Performance Insights uses an AWS KMS key to encrypt sensitive data. When you enable Performance Insights through the API or the console, you can do either of the following:

- Choose the default AWS managed key.

Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.

- Choose a customer managed key.

If you specify a customer managed key, users in your account that call the Performance Insights API need the `kms:Decrypt` and `kms:GenerateDataKey` permissions on the KMS key. You can configure these permissions through IAM policies. However, we recommend that you manage these permissions through your KMS key policy. For more information, see [Using key policies in AWS KMS](#).

Example

The following example shows how to add statements to your KMS key policy. These statements allow access to Performance Insights. Depending on how you use the KMS key, you might want to change some restrictions. Before adding statements to your policy, remove all comments.

```
{
  "Version" : "2012-10-17",
  "Id" : "your-policy",
  "Statement" : [ {
    //This represents a statement that currently exists in your policy.
  }
  ....,
  //Starting here, add new statement to your policy for Performance Insights.
  //We recommend that you add one new statement for every RDS instance
{
    "Sid" : "Allow viewing RDS Performance Insights",
    "Effect": "Allow",
  }
}
```

```
"Principal": {  
    "AWS": [  
        //One or more principals allowed to access Performance Insights  
        "arn:aws:iam::444455556666:role/Role1"  
    ]  
},  
"Action": [  
    "kms:Decrypt",  
    "kms:GenerateDataKey"  
],  
"Resource": "*",  
"Condition" : {  
    "StringEquals" : {  
        //Restrict access to only RDS APIs (including Performance Insights).  
        //Replace region with your AWS Region.  
        //For example, specify us-west-2.  
        "kms:ViaService" : "rds.region.amazonaws.com"  
    },  
    "ForAnyValue:StringEquals": {  
        //Restrict access to only data encrypted by Performance Insights.  
        "kms:EncryptionContext:aws:pi:service": "rds",  
        "kms:EncryptionContext:service": "pi",  
  
        //Restrict access to a specific RDS instance.  
        //The value is a DbiResourceId.  
        "kms:EncryptionContext:aws:rds:db-id": "db-AAAAABBBBBCCCCDDDDDEEEEEE"  
    }  
}  
}
```

Analyzing metrics with the Performance Insights dashboard

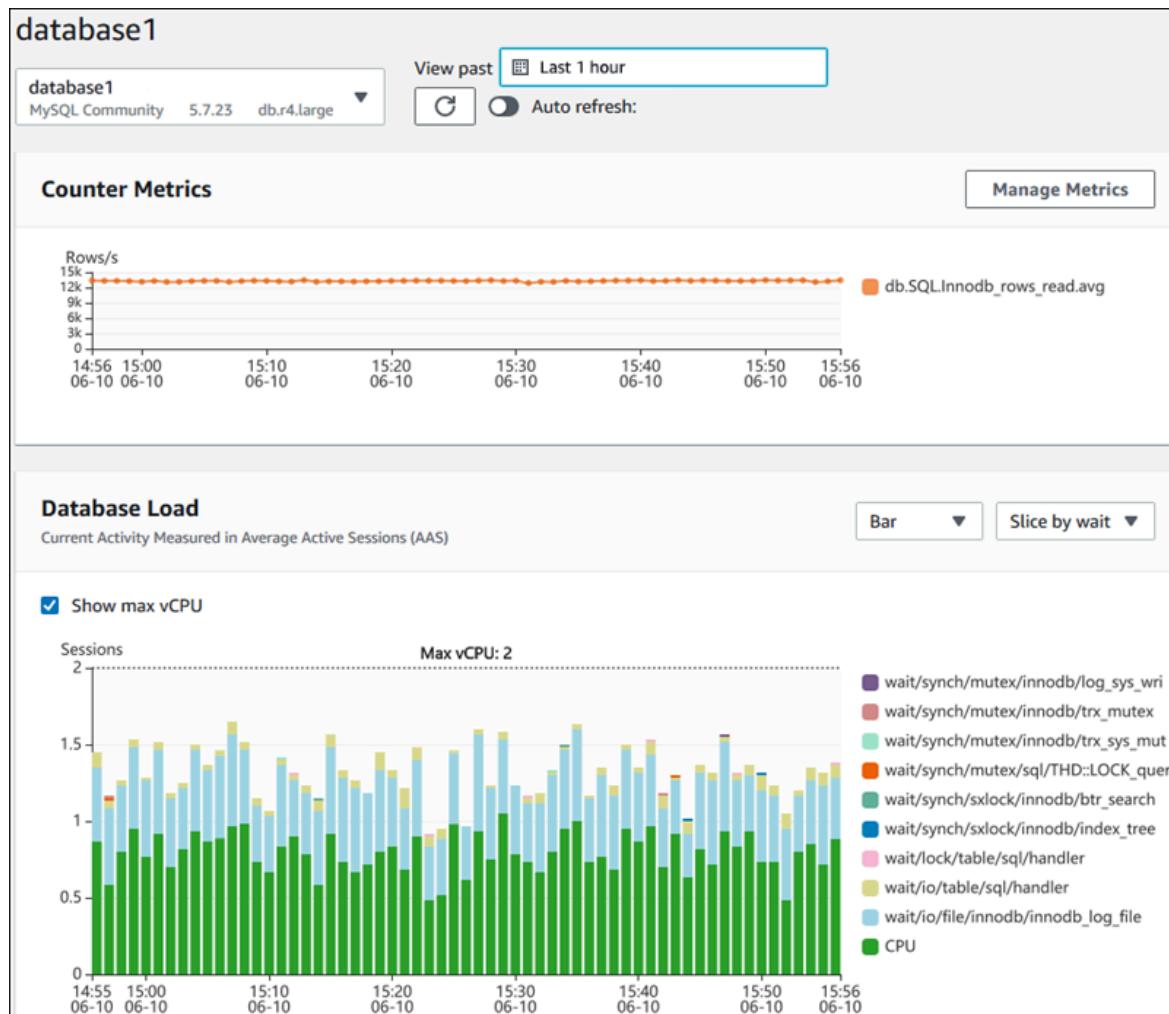

The Performance Insights dashboard contains database performance information to help you analyze and troubleshoot performance issues. On the main dashboard page, you can view information about the database load. You can "slice" DB load by dimensions such as wait events or SQL.

Performance Insights dashboard

- [Overview of the Performance Insights dashboard \(p. 559\)](#)
- [Accessing the Performance Insights dashboard \(p. 567\)](#)
- [Analyzing DB load by wait events \(p. 569\)](#)
- [Analyzing queries in the Performance Insights dashboard \(p. 570\)](#)
- [Analyzing Oracle execution plans using the Performance Insights dashboard \(p. 581\)](#)

Overview of the Performance Insights dashboard

The dashboard is the easiest way to interact with Performance Insights. The following example shows the dashboard for a MySQL DB instance.

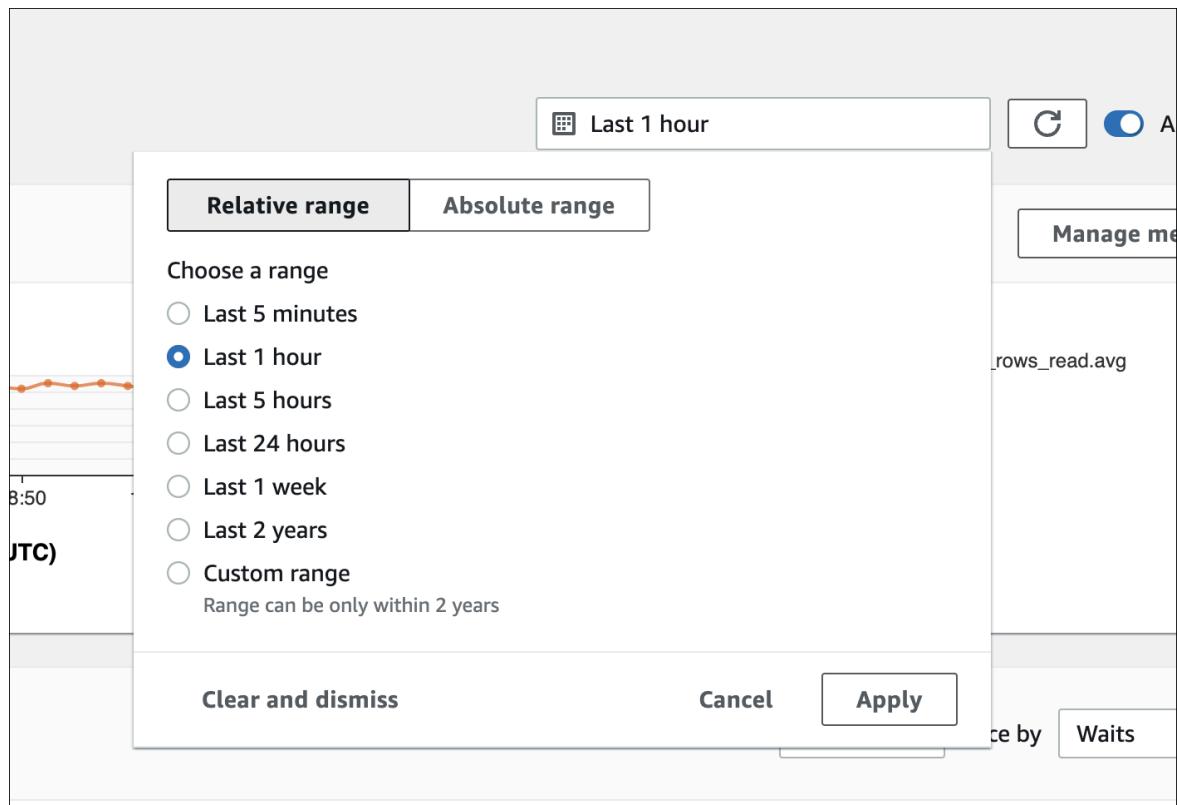

Topics

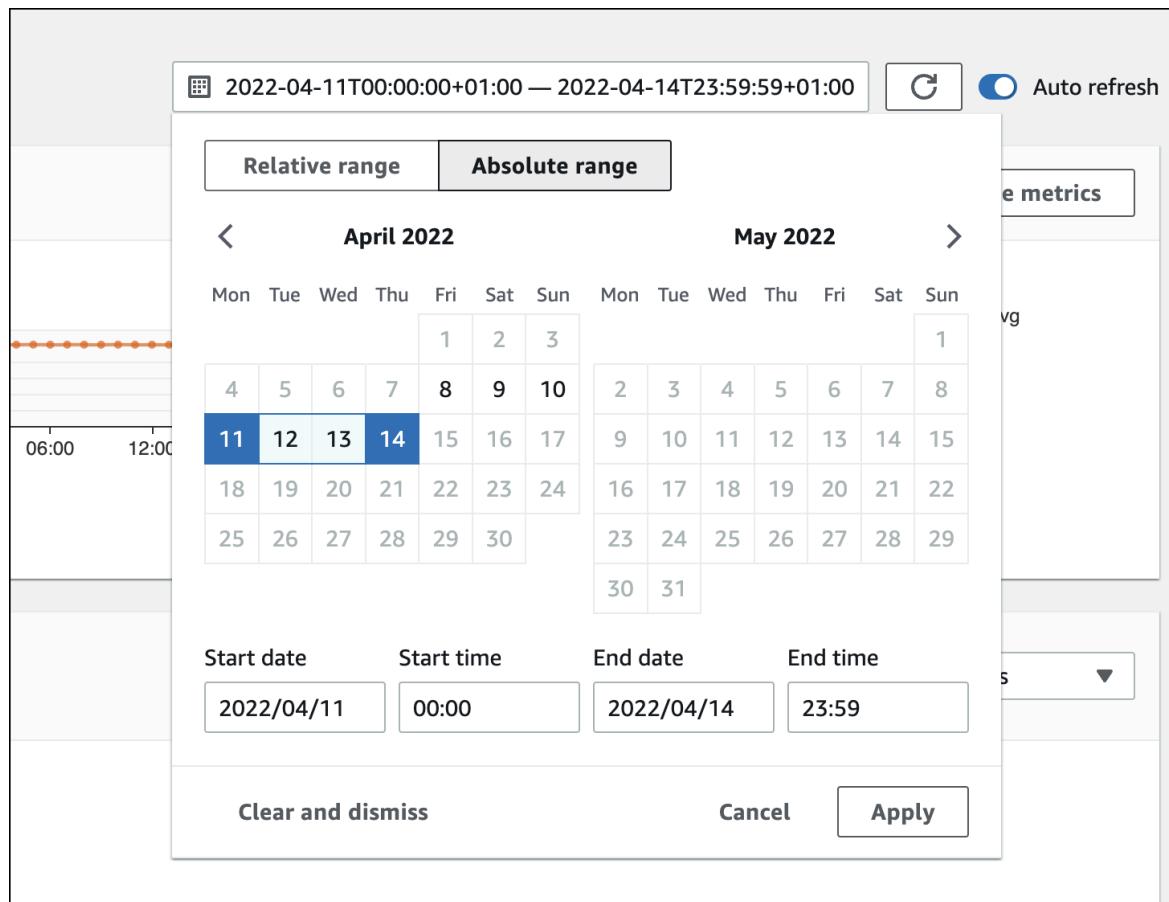

- [Time range filter \(p. 560\)](#)
- [Counter metrics chart \(p. 562\)](#)
- [Database load chart \(p. 564\)](#)
- [Top dimensions table \(p. 566\)](#)

Time range filter

By default, the Performance Insights dashboard shows DB load for the last hour. You can adjust this range to be as short as 5 minutes or as long as 2 years. You can also select a custom relative range.

You can select an absolute range with a beginning and ending date and time. The following example shows the time range beginning at midnight on 4/11/22 and ending at 11:59 PM on 4/14/22.

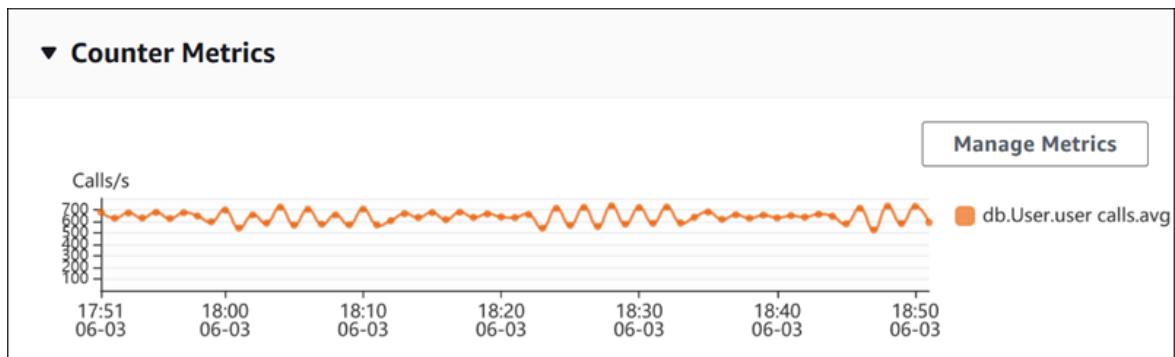

Counter metrics chart

With counter metrics, you can customize the Performance Insights dashboard to include up to 10 additional graphs. These graphs show a selection of dozens of operating system and database performance metrics. You can correlate this information with DB load to help identify and analyze performance problems.

The **Counter metrics** chart displays data for performance counters. The default metrics depend on the DB engine:

- MySQL and MariaDB – db.SQL.Innodb_rows_read.avg
- Oracle – db.User.user_calls.avg
- Microsoft SQL Server – db.Databases.Active_Transactions(_Total).avg
- PostgreSQL – db.Transactions.xact_commit.avg

To change the performance counters, choose **Manage Metrics**. You can select multiple **OS metrics** or **Database metrics**, as shown in the following screenshot. To see details for any metric, hover over the metric name.

This screenshot shows the 'Select metrics shown on the graph' dialog. It includes a search bar, tabs for 'OS metrics' (0) and 'Database metrics' (1), and a 'Clear all selections' button. The 'Database metrics' tab is selected. The interface is organized into sections: 'User' (with 'user calls' checked), 'Redo' (empty), 'Cache' (empty), and 'SQL' (empty). At the bottom are 'Cancel' and 'Update graph' buttons.

Select metrics shown on the graph

Check the metrics that you want to see on the Performance Insights dashboard.

Find metrics

OS metrics (0) Database metrics (1) Clear all selections

CPU used by this session SQL*Net roundtrips to/from client bytes received via SQL*Net from client
 user commits logons cumulative user calls
 bytes sent via SQL*Net to client user rollbacks

redo size

Cache

physical read bytes db block gets DBWR checkpoints
 physical reads consistent gets from cache db block gets from cache
 consistent gets

SQL

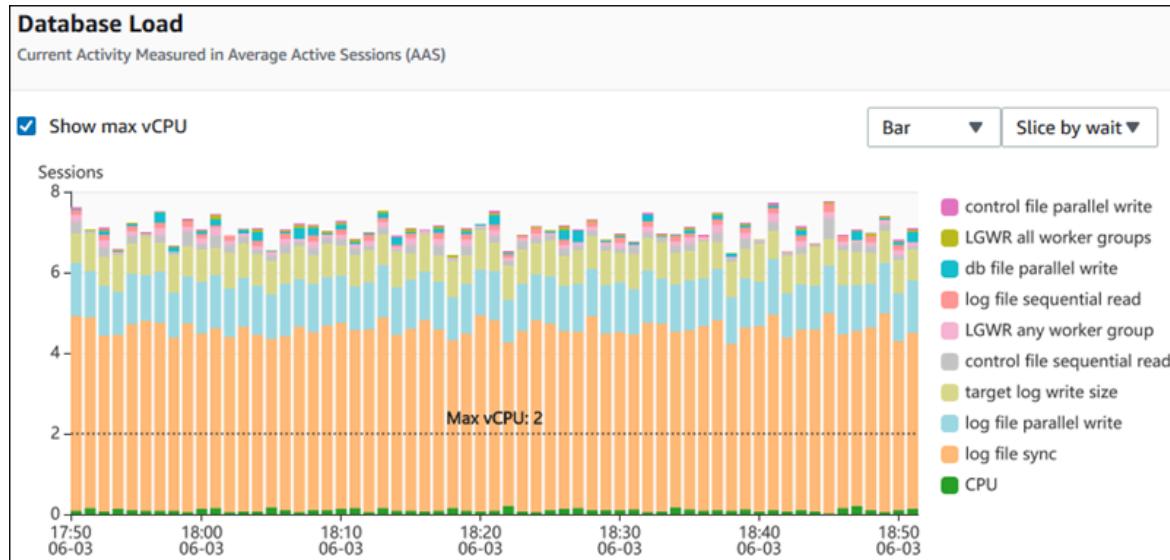

parse count (total) parse count (hard) table scan rows gotten
 sorts (memory) sorts (disk) sorts (rows)

Cancel Update graph

For descriptions of the counter metrics that you can add for each DB engine, see [Performance Insights counter metrics \(p. 618\)](#).

Database load chart

The **Database load** chart shows how the database activity compares to DB instance capacity as represented by the **Max vCPU** line. By default, the stacked line chart represents DB load as average active sessions per unit of time. The DB load is sliced (grouped) by wait states.

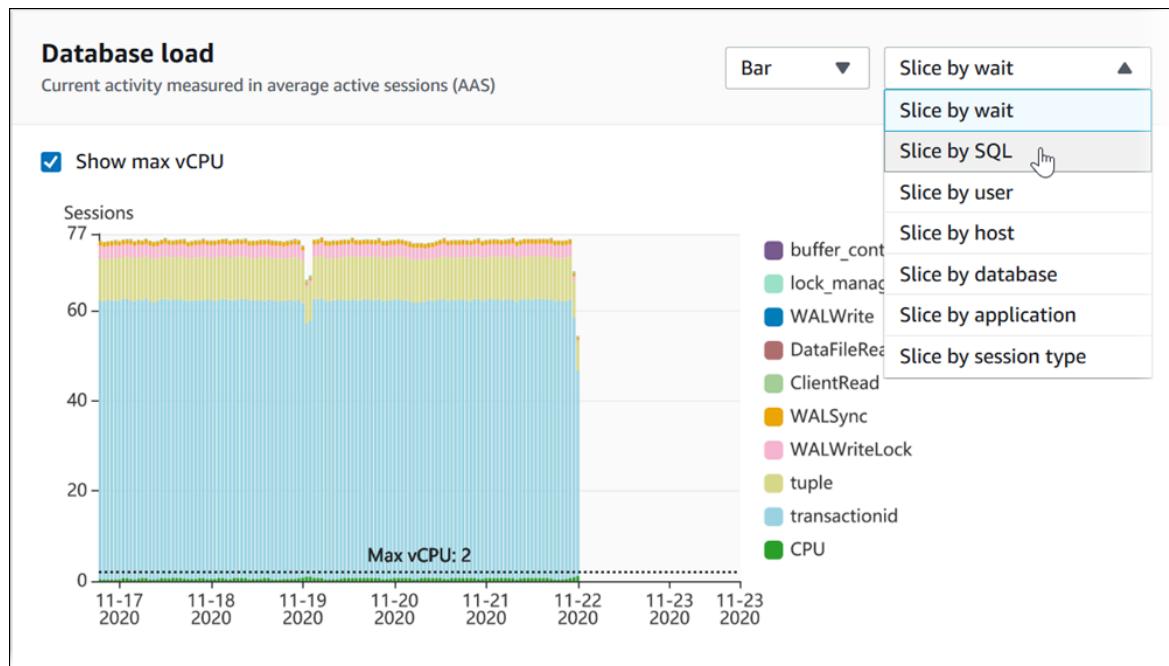

DB load sliced by dimensions

You can choose to display load as active sessions grouped by any supported dimensions. The following table shows which dimensions are supported for the different engines.

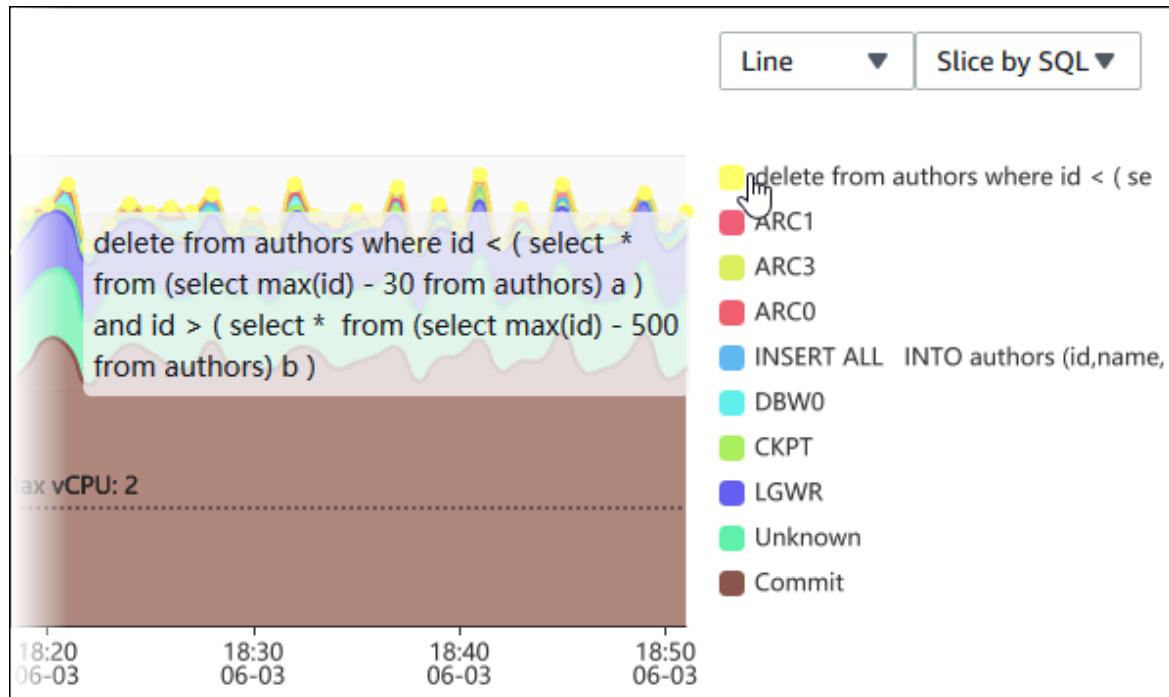

Dimension	Oracle	SQL Server	PostgreSQL	MySQL
Host	Yes	Yes	Yes	Yes
SQL	Yes	Yes	Yes	Yes
User	Yes	Yes	Yes	Yes
Waits	Yes	Yes	Yes	Yes
Plans	Yes	No	No	No
Application	No	No	Yes	No
Database	No	No	Yes	Yes
Session type	No	No	Yes	No

The following image shows the dimensions for a PostgreSQL DB instance.

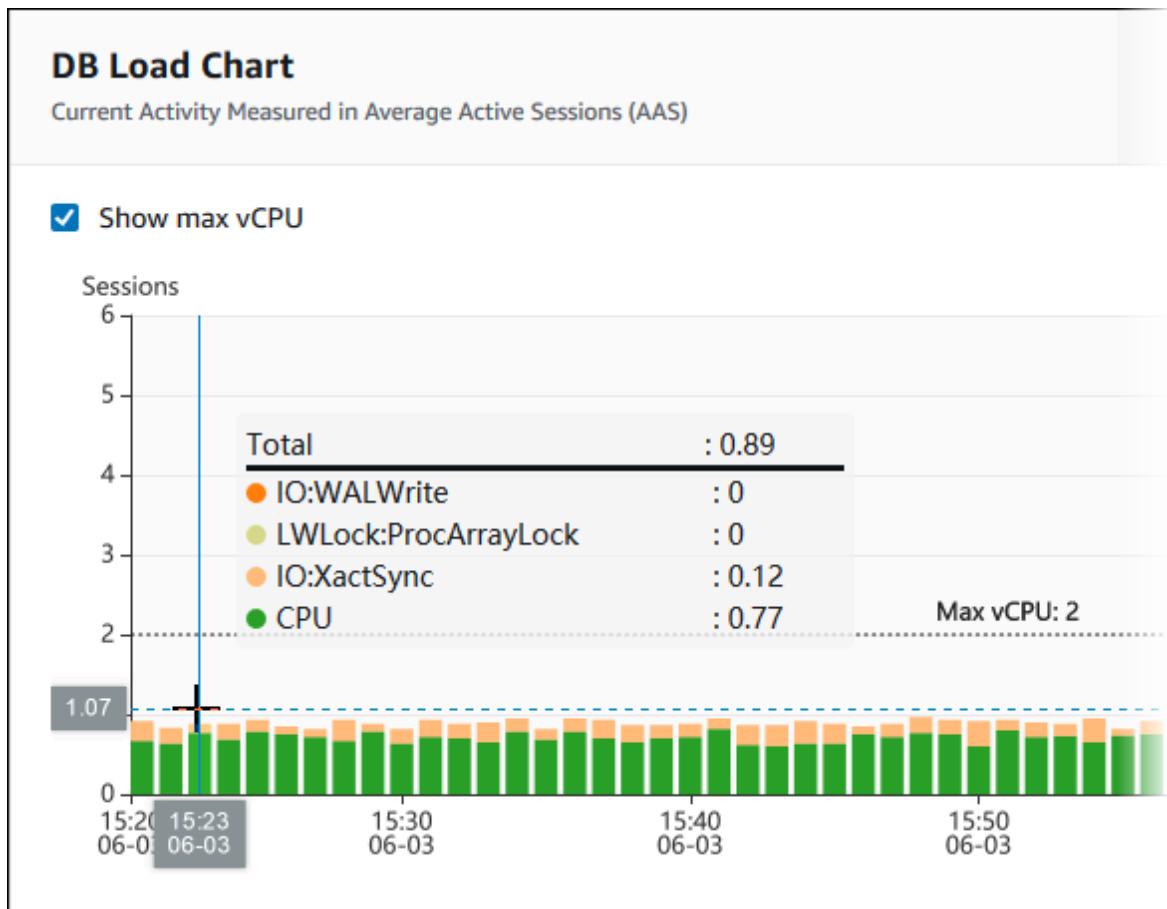

DB load details for a dimension item

To see details about a DB load item within a dimension, hover over the item name. The following image shows details for a SQL statement.

To see details for any item for the selected time period in the legend, hover over that item.

Top dimensions table

The Top dimensions table slices DB load by different dimensions. A dimension is a category or "slice by" for different characteristics of DB load. If the dimension is SQL, **Top SQL** shows the SQL statements that contribute the most to DB load.

Top waits	Top SQL	Top hosts	Top users	Top connections	Top databases	Top applications	Top session types
Top SQL (0) Learn more							
<input type="text"/> Find SQL statements							
Load by waits (AAS)				SQL statements			

Choose any of the following dimension tabs.

Tab	Description	Supported engines
Top SQL	The SQL statements that are currently running	All
Top waits	The event for which the database backend is waiting	All

Tab	Description	Supported engines
Top hosts	The host name of the connected client	All
Top users	The user logged in to the database	All
Top databases	The name of the database to which the client is connected	PostgreSQL, MySQL, and MariaDB only
Top applications	The name of the application that is connected to the database	PostgreSQL only
Top session types	The type of the current session	PostgreSQL only

To learn how to analyze queries by using the **Top SQL** tab, see [Overview of the Top SQL tab \(p. 571\)](#).

Accessing the Performance Insights dashboard

To access the Performance Insights dashboard, use the following procedure.

To view the Performance Insights dashboard in the AWS Management Console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

The Performance Insights dashboard is shown for that DB instance.

For DB instances with Performance Insights turned on, you can also reach the dashboard by choosing the **Sessions** item in the list of DB instances. Under **Current activity**, the **Sessions** item shows the database load in average active sessions over the last five minutes. The bar graphically shows the load. When the bar is empty, the DB instance is idle. As the load increases, the bar fills with blue. When the load passes the number of virtual CPUs (vCPUs) on the DB instance class, the bar turns red, indicating a potential bottleneck.

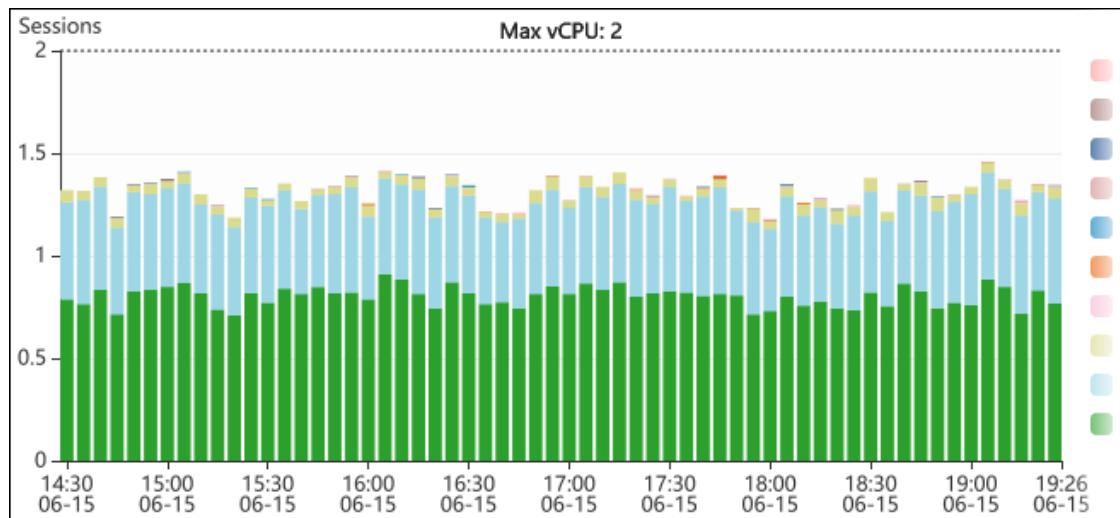

Databases		Group resources	Actions	Restore from S3	Create database
<input type="checkbox"/>	DB identifier	<input checked="" type="radio"/> Filter databases			
<input type="checkbox"/>	database1	MySQL Community	<div style="width: 45.51%;">45.51%</div>	<div style="width: 1.34%;">1.34 Sessions</div>	
<input type="checkbox"/>	database2	Oracle Enterprise Edition	<div style="width: 55.41%;">55.41%</div>	<div style="width: 3.48%;">3.48 Sessions</div>	
<input type="checkbox"/>	database3	Oracle Enterprise Edition	<div style="width: 1.02%;">1.02%</div>	<div style="width: 0%;">0 Connections</div>	

4. (Optional) Choose **View past** in the upper right and specify a different relative or absolute time interval.

In the following example, the DB load is shown for the last 5 hours.

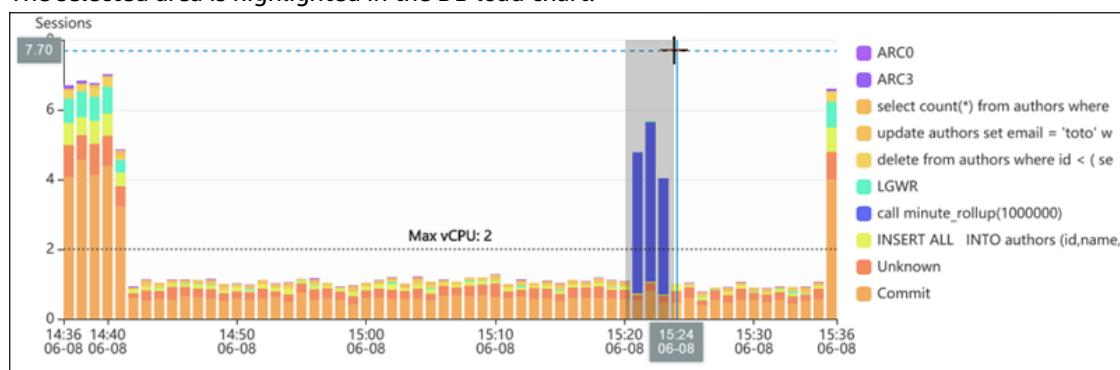

In the following screenshot, the DB load interval is 5 hours.

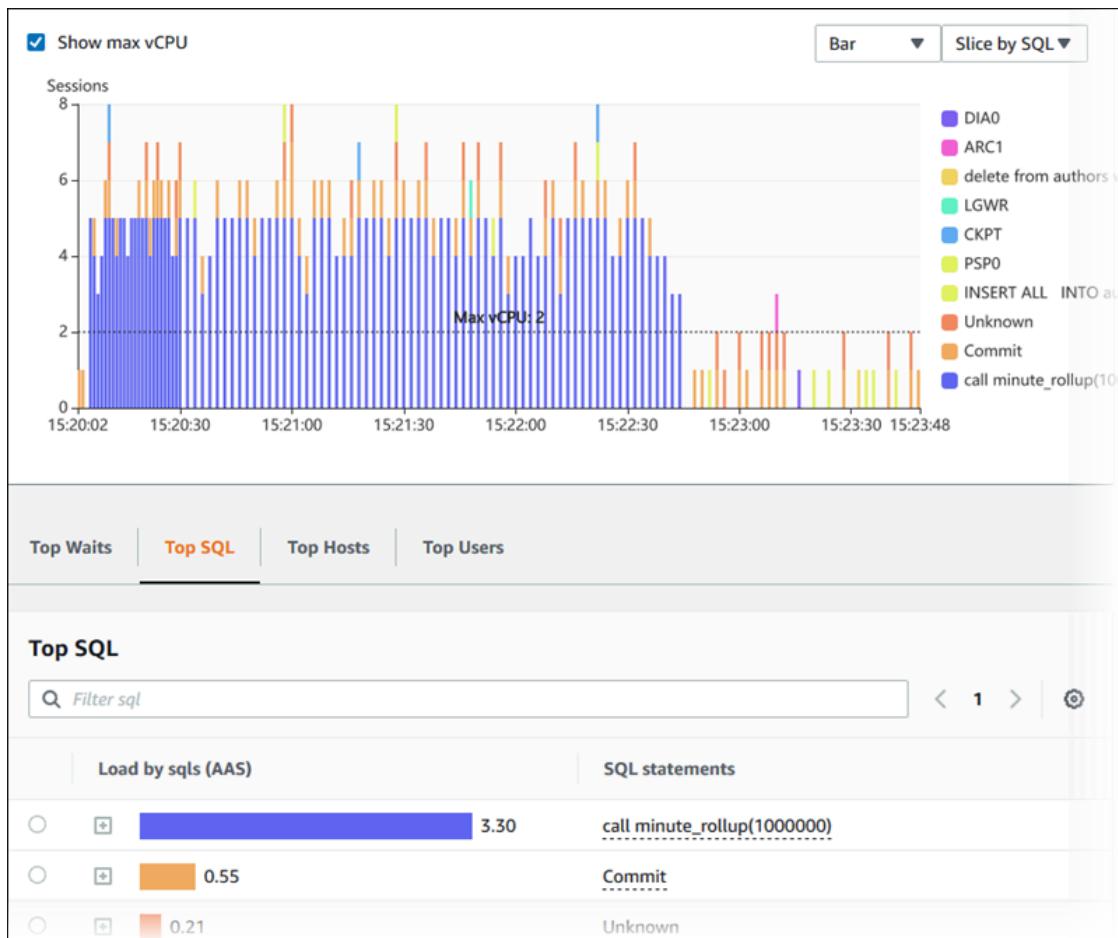

5. (Optional) To zoom in on a portion of the DB load chart, choose the start time and drag to the end of the time period you want.

The selected area is highlighted in the DB load chart.

When you release the mouse, the DB load chart zooms in on the selected AWS Region, and the **Top dimensions** table is recalculated.

6. (Optional) To refresh your data automatically, enable **Auto refresh**.

The Performance Insight dashboard automatically refreshes with new data. The refresh rate depends on the amount of data displayed:

- 5 minutes refreshes every 5 seconds.
- 1 hour refreshes every minute.
- 5 hours refreshes every minute.
- 24 hours refreshes every 5 minutes.
- 1 week refreshes every hour.

Analyzing DB load by wait events

If the **Database load** chart shows a bottleneck, you can find out where the load is coming from. To do so, look at the top load items table below the **Database load** chart. Choose a particular item, like a SQL query or a user, to drill down into that item and see details about it.

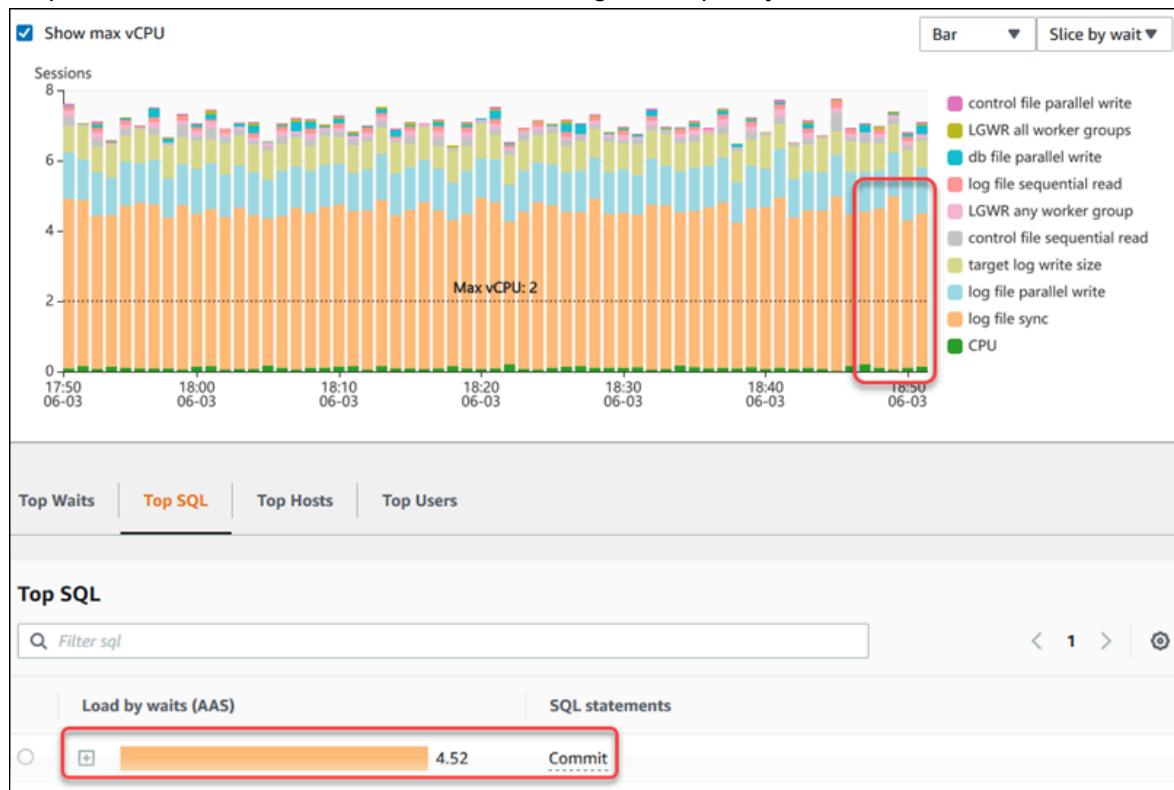

DB load grouped by waits and top SQL queries is the default Performance Insights dashboard view. This combination typically provides the most insight into performance issues. DB load grouped by waits

shows if there are any resource or concurrency bottlenecks in the database. In this case, the **SQL** tab of the top load items table shows which queries are driving that load.

Your typical workflow for diagnosing performance issues is as follows:

1. Review the **Database load** chart and see if there are any incidents of database load exceeding the **Max CPU** line.
2. If there is, look at the **Database load** chart and identify which wait state or states are primarily responsible.
3. Identify the digest queries causing the load by seeing which of the queries the **SQL** tab on the top load items table are contributing most to those wait states. You can identify these by the **DB Load by Wait** column.
4. Choose one of these digest queries in the **SQL** tab to expand it and see the child queries that it is composed of.

For example, in the dashboard following, **log file sync** waits account for most of the DB load. The **LGWR all worker groups** wait is also high. The **Top SQL** chart shows what is causing the **log file sync** waits: frequent COMMIT statements. In this case, committing less frequently will reduce DB load.

Analyzing queries in the Performance Insights dashboard

In the Amazon RDS Performance Insights dashboard, you can find information about running and recent queries in the **Top SQL** tab in the **Top dimensions** table. You can use this information to tune your queries.

Note

RDS for SQL Server doesn't show SQL-level statistics.

Topics

- [Overview of the Top SQL tab \(p. 571\)](#)
- [Accessing more SQL text in the Performance Insights dashboard \(p. 576\)](#)
- [Viewing SQL statistics in the Performance Insights dashboard \(p. 578\)](#)

Overview of the Top SQL tab

By default, the **Top SQL** tab shows the 25 queries that are contributing the most to DB load. To help tune your queries, you can analyze information such as the query text and SQL statistics. You can also choose the statistics that you want to appear in the **Top SQL** tab.

Topics

- [SQL text \(p. 571\)](#)
- [SQL statistics \(p. 572\)](#)
- [Load by waits \(AAS\) \(p. 573\)](#)
- [SQL information \(p. 573\)](#)
- [Preferences \(p. 574\)](#)

SQL text

By default, each row in the **Top SQL** table shows 500 bytes of text for each statement.

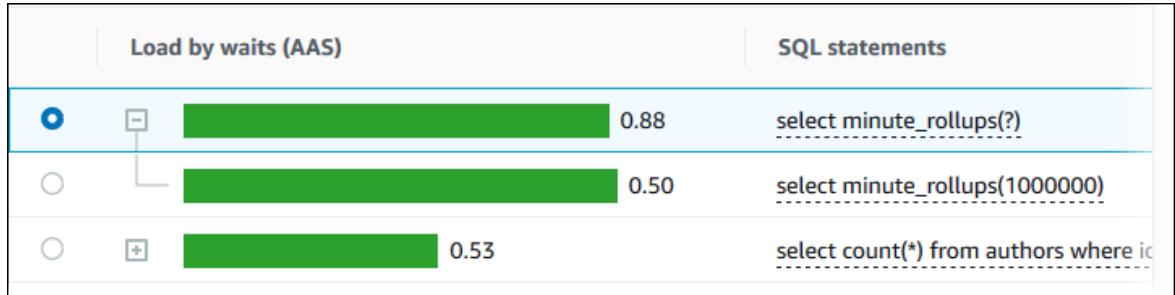

Top SQL (10) Learn more	
<input type="text"/> Find SQL statements	
Load by waits (AAS)	SQL statements
2.00	SELECT SEAT_LEVEL, SEAT_SECTION, SEAT_ROW FROM (SELECT SEAT_LEVEL, SEAT_SECTION, S...
1.71	select p.full_name, SUM(t.id) from ticket_purchase_hist h, person p, sporting_e...
1.17	SELECT MIN(SPORTING_EVENT_TICKET_ID), MAX(SPORTING_EVENT_TICKET_ID) FROM TICKET...
0.54	SELECT MAX(SPORTING_EVENT_TICKET_ID) FROM TICKET_PURCHASE_HIST WHERE SPORTING_EV...
0.15	DECLARE SqlDevBind1Z_1 VARCHAR2(32767):=SqlDevBind1ZInit1; SqlDevBind1Z_2 VARCH...
0.11	SELECT SUM(PURCHASE_PRICE) FROM TICKET_PURCHASE_HIST
0.08	UPDATE SPORTING_EVENT_TICKET SET TICKETHOLDER_ID = :B2 WHERE ID = :B1
0.04	SELECT * FROM SPORTING_EVENT_TICKET WHERE SPORTING_EVENT_ID = :B4 AND SEAT_LEVEL...

To learn how to see more than the default 500 bytes of SQL text, see [Accessing more SQL text in the Performance Insights dashboard \(p. 576\)](#).

A *SQL digest* is a composite of multiple actual queries that are structurally similar but might have different literal values. The digest replaces hardcoded values with a question mark. For example, a digest might be `SELECT * FROM emp WHERE lname= ?`. This digest might include the following child queries:

```
SELECT * FROM emp WHERE lname = 'Sanchez'  
SELECT * FROM emp WHERE lname = 'Olagappan'  
SELECT * FROM emp WHERE lname = 'Wu'
```

To see the literal SQL statements in a digest, select the query, and then choose the plus symbol (+). In the following example, the selected query is a digest.

Note

A SQL digest groups similar SQL statements, but doesn't redact sensitive information.

Performance Insights can show Oracle SQL text as **Unknown**. The text has this status in the following situations:

- An Oracle database user other than SYS is active but not currently executing SQL. For example, when a parallel query completes, the query coordinator waits for helper processes to send their session statistics. For the duration of the wait, the query text shows **Unknown**.
- For an RDS for Oracle instance on Standard Edition 2, Oracle Resource Manager limits the number of parallel threads. The background process doing this work causes the query text to show as **Unknown**.

SQL statistics

SQL statistics are performance-related metrics about SQL queries. For example, Performance Insights might show executions per second or rows processed per second. Performance Insights collects statistics for only the most common queries. Typically, these match the top queries by load shown in the Performance Insights dashboard.

Every line in the **Top SQL** table shows relevant statistics for the SQL statement or digest, as shown in the following example.

Top SQL		Filter sql	<	1	>	①
	Load by waits (AAS)	SQL statements		calls/sec	rows/sec	
○	0.88	select minute_rollups(?)		0.06	0.06	
○	0.53	select count(*) from authors where id < (select max(id) - 31 from authors) and ...		33.68	101.04	
○	0.17	WITH cte AS (SELECT id FROM authors LIMIT ?) UPDATE ...		33.68	33.68	
○	0.08	delete from authors where id < (select * from (select max(id) - ? from authors) ...		33.68	303.13	
○	0.07	INSERT INTO authors (id,name,email) VALUES (nextval(?),?,(nextval(?),? ,...)		33.68	303.13	
○	0.06	select count(*) from authors where id < (select max(id) - 31 from authors) and ...		0.00	0.00	

Performance Insights can report **0.00** and **- (unknown)** for SQL statistics. This situation occurs under the following conditions:

- Only one sample exists. For example, Performance Insights calculates rates of change for RDS PostgreSQL queries based on multiple samples from the pg_stats_statements view. When a workload runs for a short time, Performance Insights might collect only one sample, which means that it can't calculate a rate of change. The unknown value is represented with a dash (-).
- Two samples have the same values. Performance Insights can't calculate a rate of change because no change has occurred, so it reports the rate as **0.00**.
- An RDS PostgreSQL statement lacks a valid identifier. PostgreSQL creates a identifier for a statement only after parsing and analysis. Thus, a statement can exist in the PostgreSQL internal in-memory

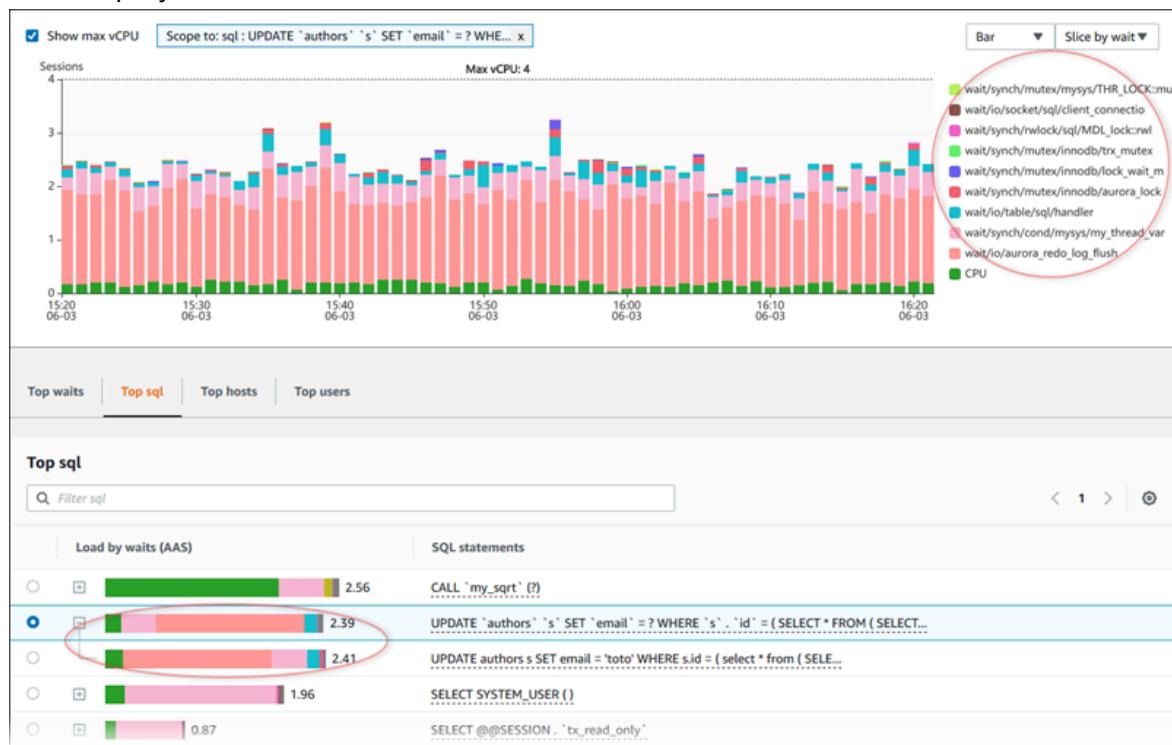

structures with no identifier. Because Performance Insights samples internal in-memory structures once per second, low-latency queries might appear for only a single sample. If the query identifier isn't available for this sample, Performance Insights can't associate this statement with its statistics. The unknown value is represented with a dash (-).

For a description of the SQL statistics for the Amazon RDS engines, see [SQL statistics for Performance Insights \(p. 628\)](#).

Load by waits (AAS)

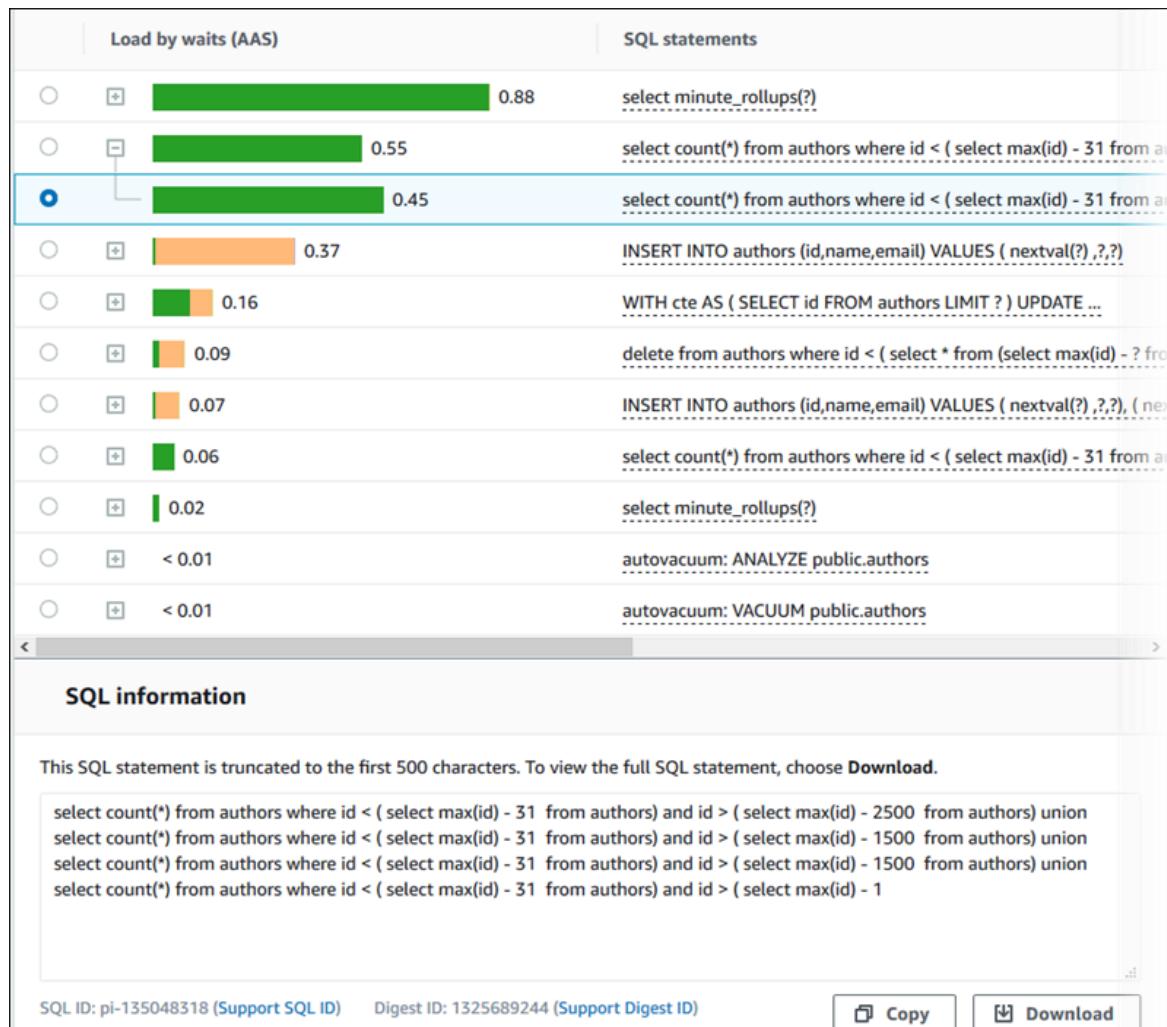

In **Top SQL**, the **Load by waits (AAS)** column illustrates the percentage of the database load associated with each top load item. This column reflects the load for that item by whatever grouping is currently selected in the **DB Load Chart**.

For example, you might group the **DB load** chart by wait states. You examine SQL queries in the top load items table. In this case, the **DB Load by Waits** bar is sized, segmented, and color-coded to show how much of a given wait state that query is contributing to. It also shows which wait states are affecting the selected query.

SQL information

In the **Top SQL** table, you can open a statement to view its information. The information appears in the bottom pane.

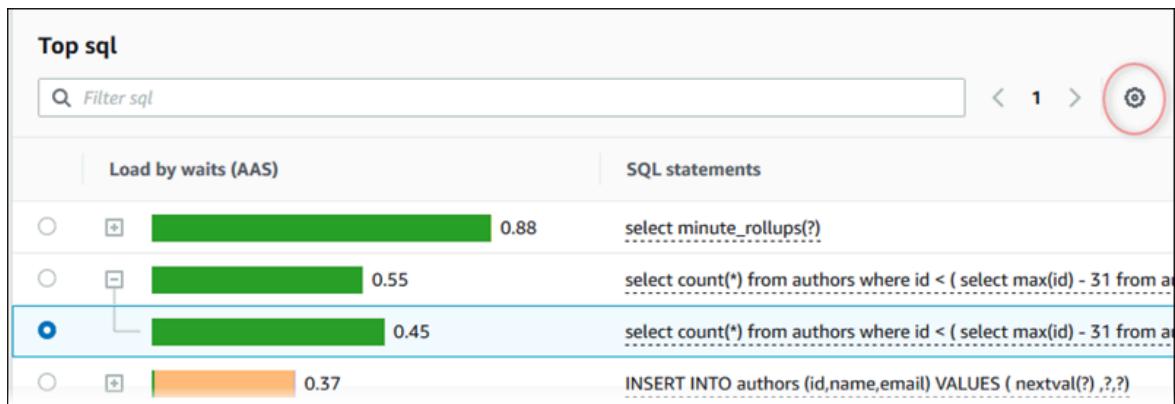

The following types of identifiers (IDs) that are associated with SQL statements:

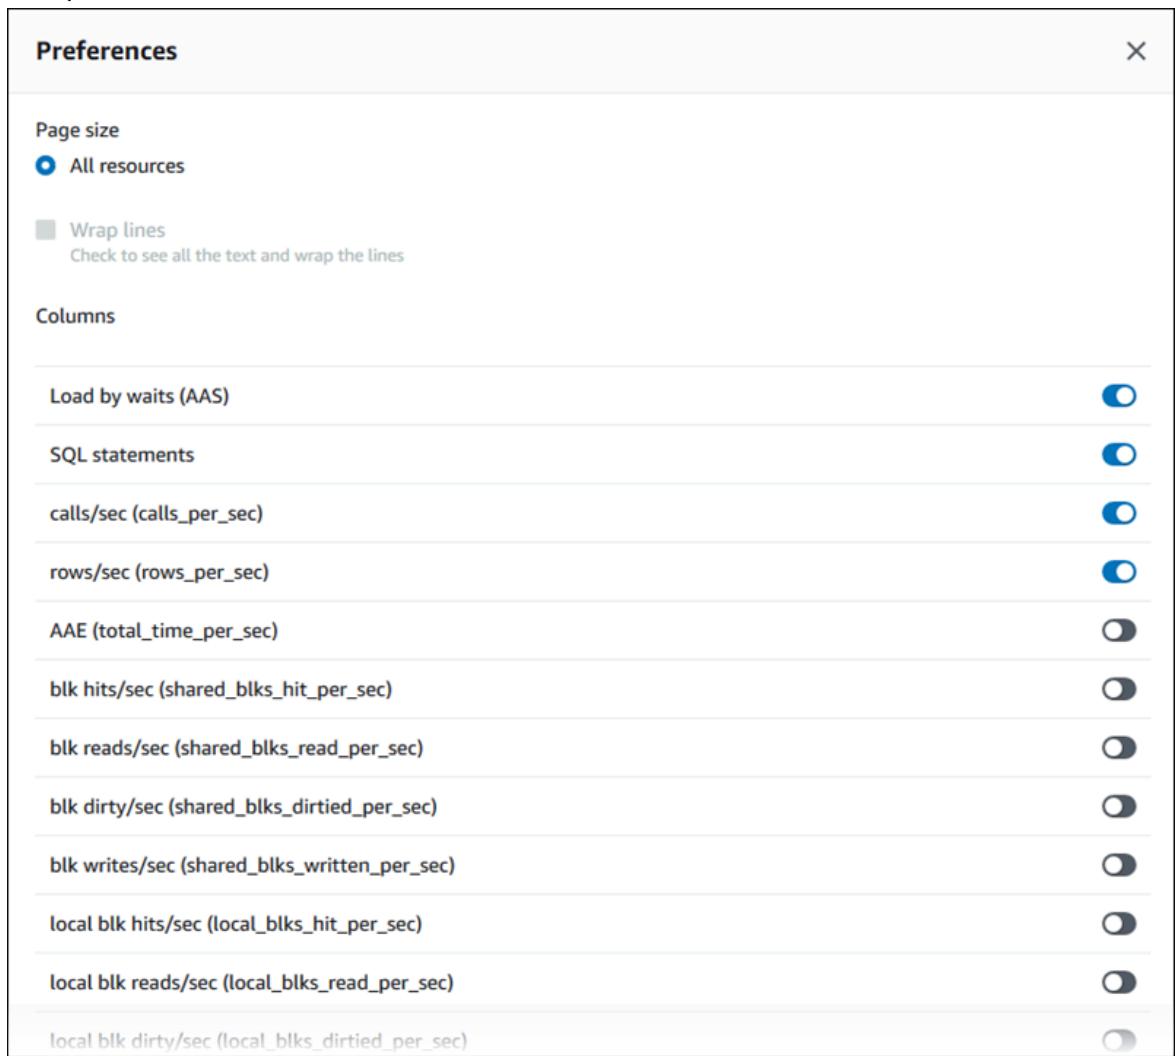

- **Support SQL ID** – A hash value of the SQL ID. This value is only for referencing a SQL ID when you are working with AWS Support. AWS Support doesn't have access to your actual SQL IDs and SQL text.
- **Support Digest ID** – A hash value of the digest ID. This value is only for referencing a digest ID when you are working with AWS Support. AWS Support doesn't have access to your actual digest IDs and SQL text.

Preferences

You can control the statistics displayed in the **Top SQL** tab by choosing the **Preferences** icon.

When you choose the **Preferences** icon, the **Preferences** window opens. The following screenshot is an example of the **Preferences** window.

To enable the statistics that you want to appear in the **Top SQL** tab, use your mouse to scroll to the bottom of the window, and then choose **Continue**.

For more information about per-second or per-call statistics for the Amazon RDS engines, see the engine specific SQL statistics section in [SQL statistics for Performance Insights \(p. 628\)](#)

Accessing more SQL text in the Performance Insights dashboard

By default, each row in the **Top SQL** table shows 500 bytes of SQL text for each SQL statement.

When a SQL statement exceeds 500 bytes, you can view more text in the **SQL text** section below the **Top SQL** table. In this case, the maximum length for the text displayed in **SQL text** is 4 KB. This limit is introduced by the console and is subject to the limits set by the database engine. To save the text shown in **SQL text**, choose **Download**.

Topics

- [Text size limits for Amazon RDS engines \(p. 576\)](#)
- [Setting the SQL text limit for Amazon RDS for PostgreSQL DB instances \(p. 576\)](#)
- [Viewing and downloading SQL text in the Performance Insights dashboard \(p. 577\)](#)

Text size limits for Amazon RDS engines

When you download SQL text, the database engine determines its maximum length. You can download SQL text up to the following per-engine limits.

DB engine	Maximum length of downloaded text
Amazon RDS for MySQL and MariaDB	1,024 bytes
Amazon RDS for Microsoft SQL Server	4,096 characters
Amazon RDS for Oracle	1,000 bytes

The **SQL text** section of the Performance Insights console displays up to the maximum that the engine returns. For example, if MySQL returns at most 1 KB to Performance Insights, it can only collect and show 1 KB, even if the original query is larger. Thus, when you view the query in **SQL text** or download it, Performance Insights returns the same number of bytes.

If you use the AWS CLI or API, Performance Insights doesn't have the 4 KB limit enforced by the console. `DescribeDimensionKeys` and `GetResourceMetrics` return at most 500 bytes. `GetDimensionKeyDetails` returns the full query, but the size is subject to the engine limit.

Setting the SQL text limit for Amazon RDS for PostgreSQL DB instances

Amazon RDS for PostgreSQL handles text differently. You can set the text size limit with the DB instance parameter `track_activity_query_size`. This parameter has the following characteristics:

Default text size

On Amazon RDS for PostgreSQL version 9.6, the default setting for the `track_activity_query_size` parameter is 1,024 bytes. On Amazon RDS for PostgreSQL version 10 or higher, the default is 4,096 bytes.

Maximum text size

The limit for `track_activity_query_size` is 102,400 bytes for Amazon RDS for PostgreSQL version 12 and lower. The maximum is 1 MB for version 13 and higher.

If the engine returns 1 MB to Performance Insights, the console displays only the first 4 KB. If you download the query, you get the full 1 MB. In this case, viewing and downloading return different numbers of bytes. For more information about the `track_activity_query_size` DB instance parameter, see [Run-time Statistics](#) in the PostgreSQL documentation.

To increase the SQL text size, increase the `track_activity_query_size` limit. To modify the parameter, change the parameter setting in the parameter group that is associated with the Amazon RDS for PostgreSQL DB instance.

To change the setting when the instance uses the default parameter group

1. Create a new DB instance parameter group for the appropriate DB engine and DB engine version.
2. Set the parameter in the new parameter group.
3. Associate the new parameter group with the DB instance.

For information about setting a DB instance parameter, see [Modifying parameters in a DB parameter group \(p. 294\)](#).

Viewing and downloading SQL text in the Performance Insights dashboard

In the Performance Insights dashboard, you can view or download SQL text.

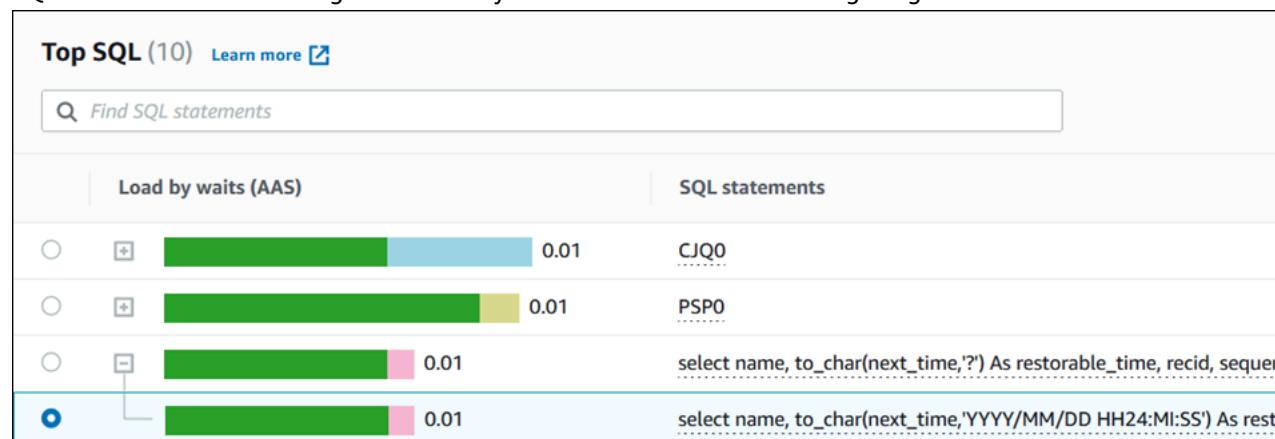

To view more SQL text in the Performance Insights dashboard

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

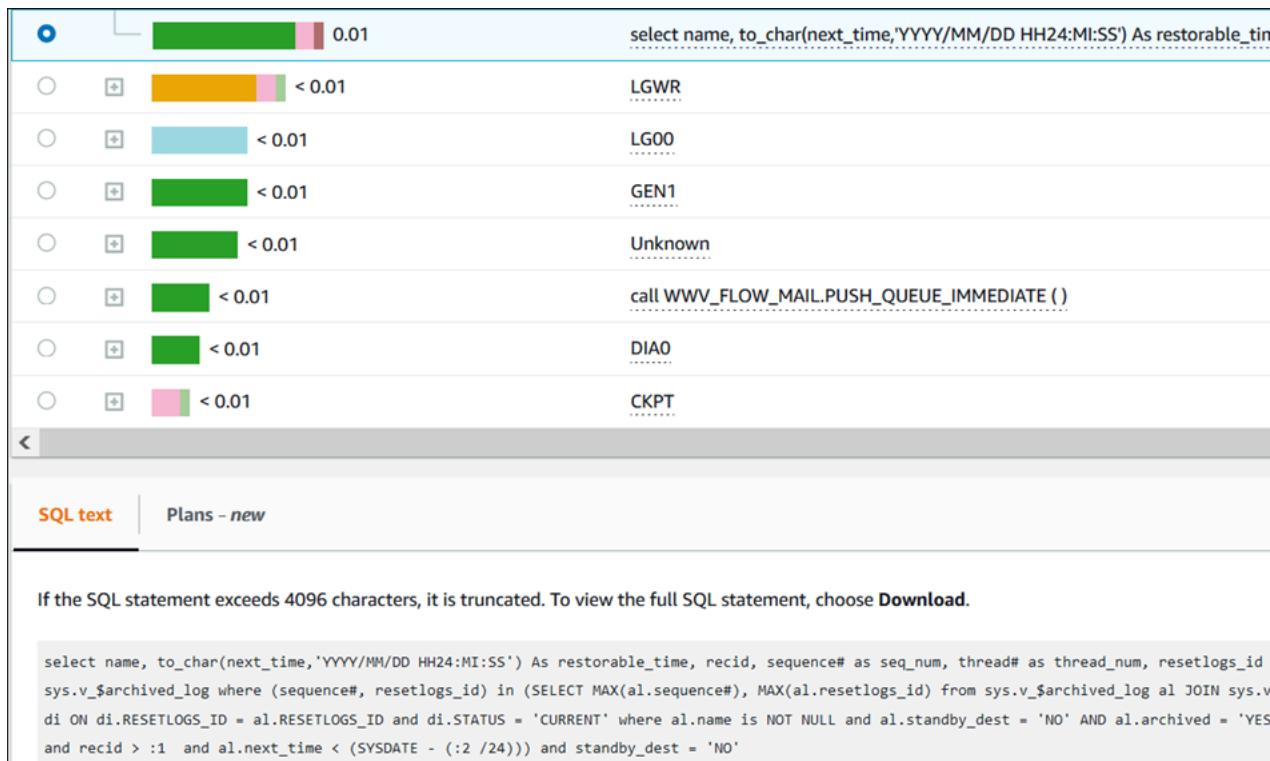

The Performance Insights dashboard is displayed for your DB instance.

4. Scroll down to the **Top SQL** tab.
5. Choose a SQL statement.

SQL statements with text larger than 500 bytes look similar to the following image.

6. Scroll down to the **SQL text** tab.

The Performance Insights dashboard can display up to 4,096 bytes for each SQL statement.

7. (Optional) Choose **Copy** to copy the displayed SQL statement, or choose **Download** to download the SQL statement to view the SQL text up to the DB engine limit.

Note

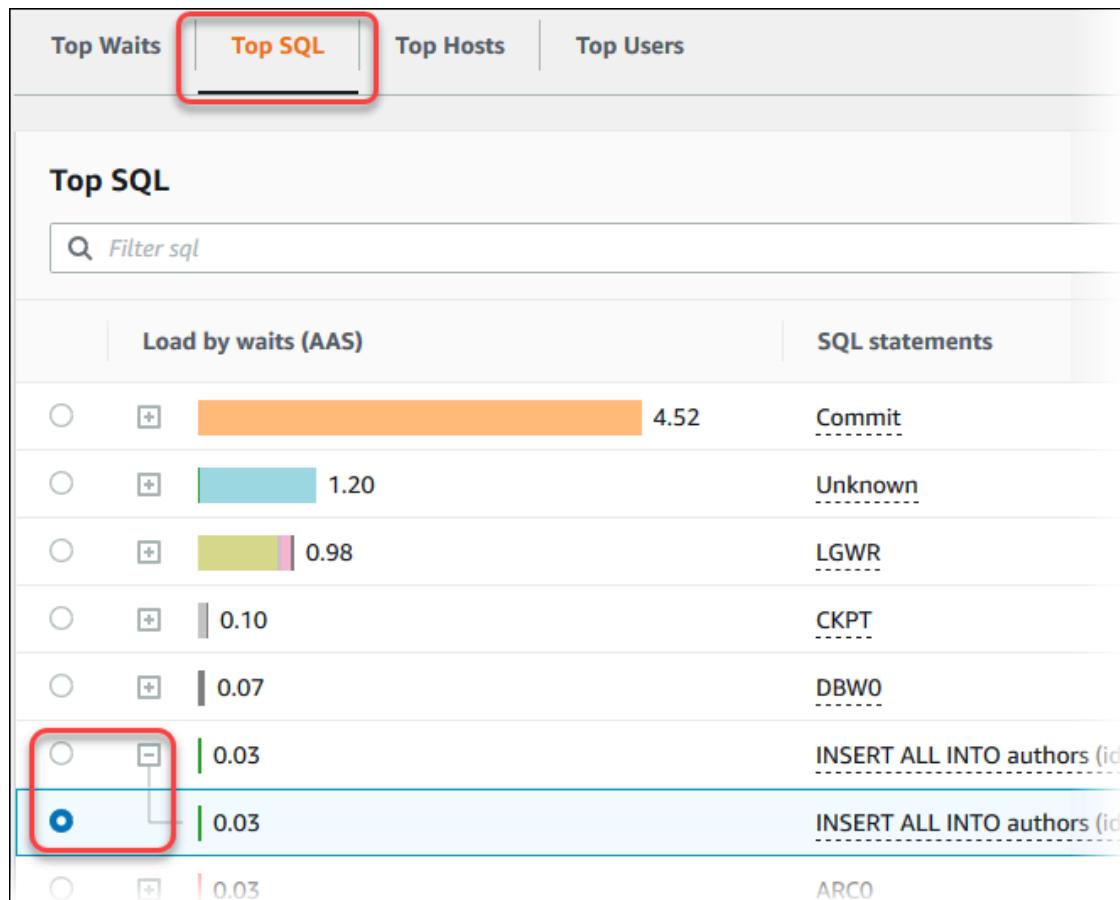

To copy or download the SQL statement, disable pop-up blockers.

Viewing SQL statistics in the Performance Insights dashboard

In the Performance Insights dashboard, SQL statistics are available in the **Top SQL** tab of the **Database load** chart.

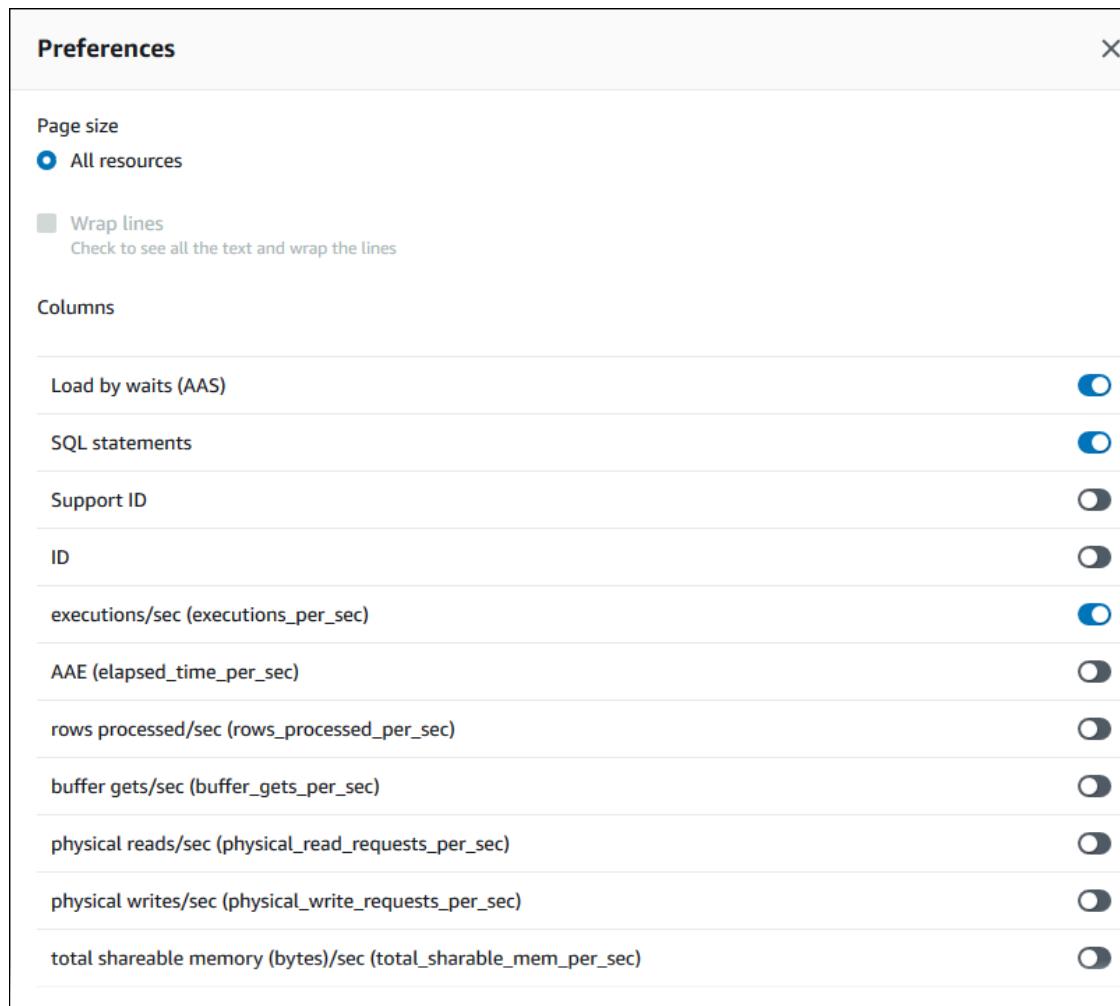

To view SQL statistics

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the left navigation pane, choose **Performance Insights**.
3. At the top of the page, choose the database whose SQL statistics you want to see.
4. Scroll to the bottom of the page and choose the **Top SQL** tab.
5. Choose an individual statement or digest query.

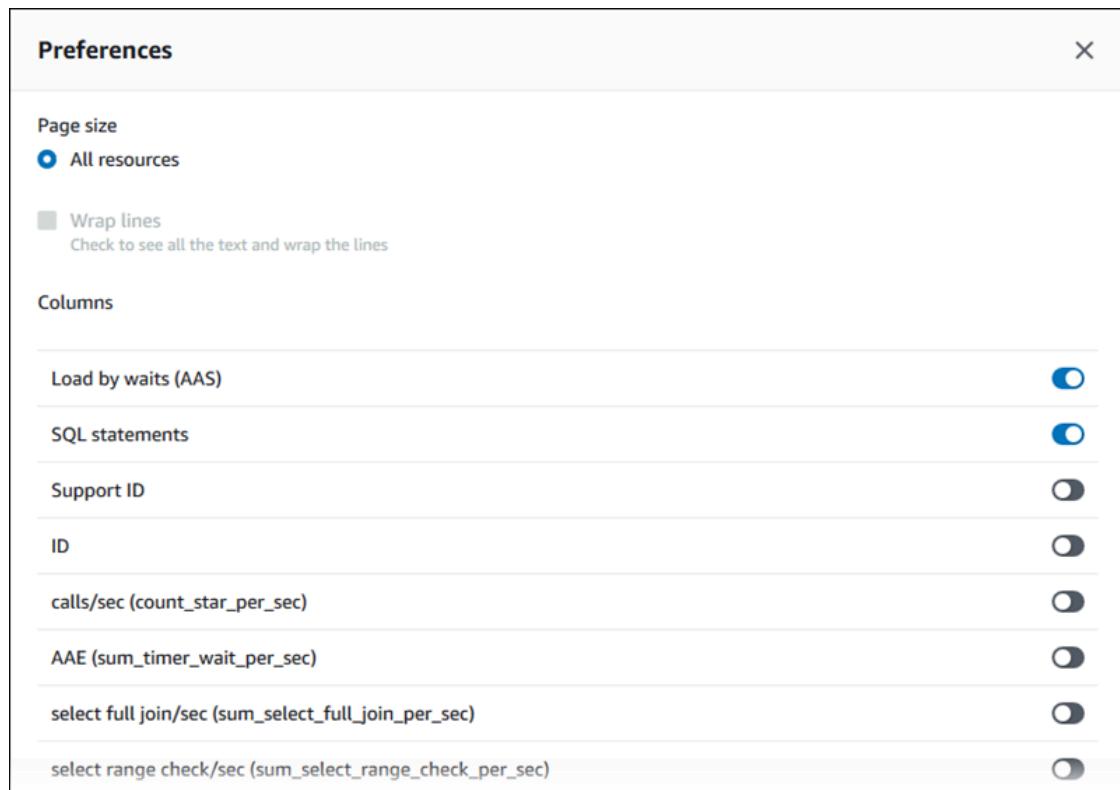

6. Choose which statistics to display by choosing the gear icon in the upper-right corner of the chart. For descriptions of the SQL statistics for the Amazon RDS engines, see [SQL statistics for Performance Insights \(p. 628\)](#).

The following example shows the statistics preferences for Oracle DB instances.

The following example shows the preferences for MariaDB and MySQL DB instances.

7. Choose Save to save your preferences.

The **Top SQL** table refreshes.

The following example shows statistics for an Oracle SQL query.

SQL statements	executions/sec	elapsed time (ms)
Commit	-	-
Unknown	-	-
LGWR	-	-
CKPT	-	-
DBWO	-	-
INSERT ALL INTO authors (id,name,email) VALUES (serial.nextval , 'Priya' , 'p@g...')	-	-
INSERT ALL INTO authors (id,name,email) VALUES (serial.nextval , 'Priya' , 'p@g...')	73.38	0.56
ARC0	-	-

Analyzing Oracle execution plans using the Performance Insights dashboard

When analyzing DB load on an Oracle Database, you might want to know which plans are contributing the most to DB load. For example, the top SQL statements at a given time might be using the plans shown in the following table.

Top SQL	Plan
SELECT SUM(amount_sold) FROM sales WHERE prod_id = 10	Plan A
SELECT SUM(amount_sold) FROM sales WHERE prod_id = 521	Plan B
SELECT SUM(s_total) FROM sales WHERE region = 10	Plan A
SELECT * FROM emp WHERE emp_id = 1000	Plan C
SELECT SUM(amount_sold) FROM sales WHERE prod_id = 72	Plan A

With the plan feature of Performance Insights, you can do the following:

- Find out which plans are used by the top SQL queries.

For example, you might find out that most of the DB load is generated by queries using plan A and plan B, with only a small percentage using plan C.

- Compare different plans for the same query.

In the preceding example, three queries are identical except for the product ID. Two queries use plan A, but one query uses plan B. To see the difference in the two plans, you can use Performance Insights.

- Find out when a query switched to a new plan.

You might see that a query used plan A and then switched to plan B at a certain time. Was there a change in the database at this point? For example, if a table is empty, the optimizer might choose a full table scan. If the table is loaded with a million rows, the optimizer might switch to an index range scan.

- Drill down to the specific steps of a plan with the highest cost.

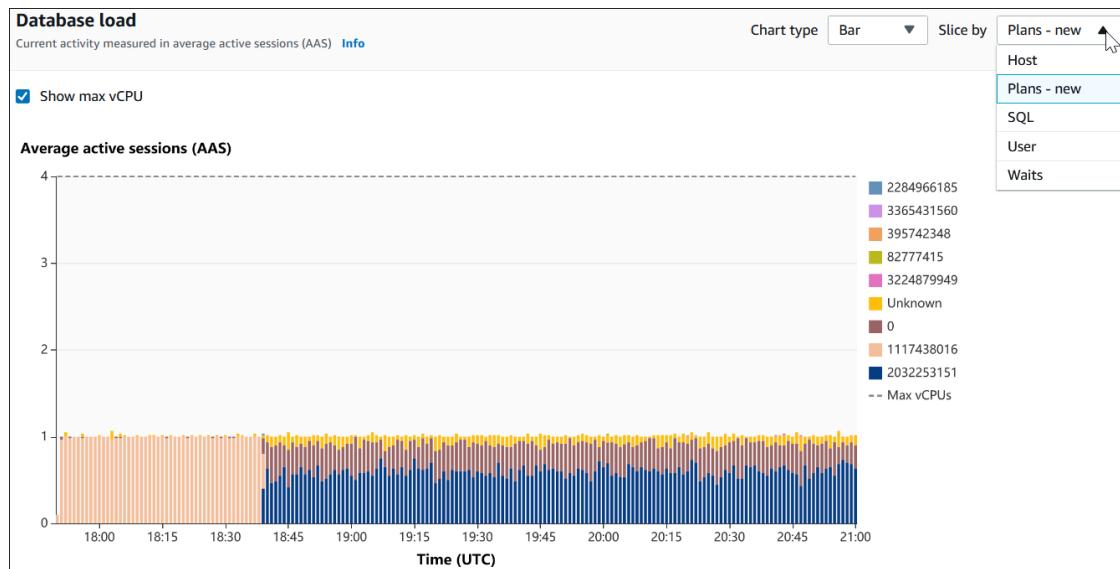

For example, the for a long-running query might show a missing a join condition in an equijoin. This missing condition forces a Cartesian join, which joins all rows of two tables.

You can perform the preceding tasks by using the plan capture feature of Performance Insights. Just as you can slice Oracle queries by wait events and top SQL, you can slice them by the plan dimension.

To analyze Oracle execution plans using the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose an Oracle DB instance. The Performance Insights dashboard is displayed for that DB instance.
4. In the **Database load (DB load)** section, choose **Plans** next to **Slice by**.

The Average active sessions chart shows the plans used by your top SQL statements. The plan hash values appear to the right of the color-coded squares. Each hash value uniquely identifies a plan.

5. Scroll down to the Top SQL tab.

In the following example, the top SQL digest has two plans. You can tell that it's a digest by the question mark in the statement.

Top SQL (10) Learn more				
Load by plans (AAS)		SQL statements	Execution...	Plans cou...
<input type="radio"/>	0.36	SELECT /* samedigest */ count(col1) FROM tab1 WHERE col1=?	1611.28	2 plans
<input type="radio"/>	0.24	DECLARE l_output NUMBER; BEGIN while true loop FOR i IN 1..2000 LOOP ...	0.00	0 plans
<input type="radio"/>	0.02	SELECT	0.00	0 plans
<input type="radio"/>	0.02	Unknown	0.00	0 plans
<input type="radio"/>	0.01	PL/SQL EXECUTE	0.00	0 plans
<input type="radio"/>	< 0.01	PSPO	0.00	0 plans
<input type="radio"/>	< 0.01	DIAO	0.00	0 plans
<input type="radio"/>	< 0.01	CKPT	0.00	0 plans
<input type="radio"/>	< 0.01	LGWR	0.00	0 plans
<input type="radio"/>	< 0.01	SELECT /* diffdigest1469 */ count(col1) FROM tab1 WHERE col1=?	7.74	1 plans

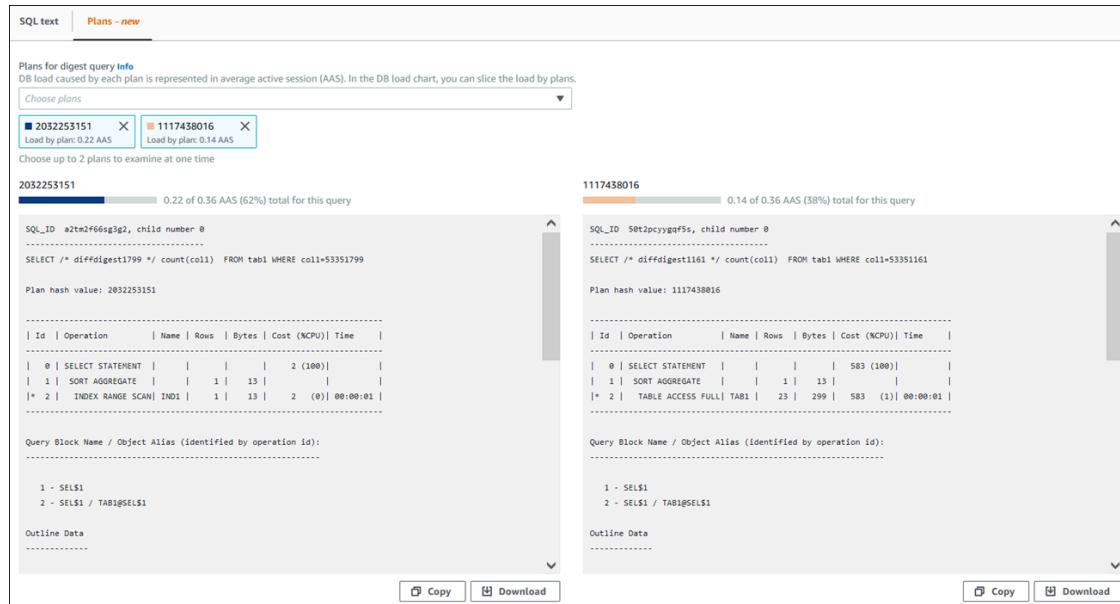

6. Choose the digest to expand it into its component statements.

In the following example, the SELECT statement is a digest query. The component queries in the digest use two different plans. The colors of the plans correspond to the database load chart. The total number of plans in the digest is shown in the second column.

Load by plans (AAS)		SQL statements	Execution...	Plans cou...
<input checked="" type="radio"/>	0.36	SELECT /* samedigest */ count(col1) FROM tab1 WHERE col1=?	1611.28	2 plans
<input type="radio"/>	< 0.01	SELECT /* samedigest */ count(col1) FROM tab1 WHERE col1=996827	7.43	1 plans
<input type="radio"/>	< 0.01	SELECT /* samedigest */ count(col1) FROM tab1 WHERE col1=9961296	6.81	0 plans
<input type="radio"/>	< 0.01	SELECT /* samedigest */ count(col1) FROM tab1 WHERE col1=996889	8.34	0 plans
<input type="radio"/>	< 0.01	SELECT /* samedigest */ count(col1) FROM tab1 WHERE col1=996503	8.67	0 plans

7. Scroll down and choose two Plans to compare from Plans for digest query list.

You can view either one or two plans for a query at a time. The following screenshot compares the two plans in the digest, with hash 2032253151 and hash 1117438016. In the following example, 62% of the average active sessions running this digest query are using the plan on the left, whereas 38% are using the plan on the right.

In this example, the plans differ in an important way. Step 2 in plan 2032253151 uses an index scan, whereas plan 1117438016 uses a full table scan. For a table with a large number of rows, a query of a single row is almost always faster with an index scan.

8. (Optional) Choose **Copy** to copy the plan to the clipboard, or **Download** to save the plan to your hard drive.

Retrieving metrics with the Performance Insights API

When Performance Insights is enabled, the API provides visibility into instance performance. Amazon CloudWatch Logs provides the authoritative source for vended monitoring metrics for AWS services.

Performance Insights offers a domain-specific view of database load measured as average active sessions (AAS). This metric appears to API consumers as a two-dimensional time-series dataset. The time dimension of the data provides DB load data for each time point in the queried time range. Each time point decomposes overall load in relation to the requested dimensions, such as SQL, Wait-event, User, or Host, measured at that time point.

Amazon RDS Performance Insights monitors your Amazon RDS DB instance so that you can analyze and troubleshoot database performance. One way to view Performance Insights data is in the AWS Management Console. Performance Insights also provides a public API so that you can query your own data. You can use the API to do the following:

- Offload data into a database
- Add Performance Insights data to existing monitoring dashboards
- Build monitoring tools

To use the Performance Insights API, enable Performance Insights on one of your Amazon RDS DB instances. For information about enabling Performance Insights, see [Turning Performance Insights on and off \(p. 549\)](#). For more information about the Performance Insights API, see the [Amazon RDS Performance Insights API Reference](#).

The Performance Insights API provides the following operations.

Performance Insights action	AWS CLI command	Description
DescribeDimensionKeys	<code>aws pi describe-dimension-keys</code>	Retrieves the top N dimension keys for a metric for a specific time period.
GetDimensionKeyDetails	<code>aws pi get-dimension-key-details</code>	Retrieves the attributes of the specified dimension group for a DB instance or data source. For example, if you specify a SQL ID, and if the dimension details are available, <code>GetDimensionKeyDetails</code> retrieves the full text of the dimension <code>db.sql.statement</code> associated with this ID. This operation is useful because <code>GetResourceMetrics</code> and <code>DescribeDimensionKeys</code> don't support retrieval of large SQL statement text.
GetResourceMetadata	<code>aws pi get-resource-metadata</code>	Retrieve the metadata for different features. For example, the metadata might indicate that a feature is turned on or off on a specific DB instance.
GetResourceMetrics	<code>aws pi get-resource-metrics</code>	Retrieves Performance Insights metrics for a set of data sources over a time period. You can provide specific dimension groups and dimensions, and provide aggregation and filtering criteria for each group.
ListAvailableResourceDimensions	<code>aws pi list-available-resource-dimensions</code>	Retrieve the dimensions that can be queried for each specified metric type on a specified instance.
ListAvailableResourceMetrics	<code>aws pi list-available-resource-metrics</code>	Retrieve all available metrics of the specified metric types that can be queried for a specified DB instance.

- [Retrieving time-series metrics \(p. 586\)](#)
- [AWS CLI examples for Performance Insights \(p. 587\)](#)

AWS CLI for Performance Insights

You can view Performance Insights data using the AWS CLI. You can view help for the AWS CLI commands for Performance Insights by entering the following on the command line.

```
aws pi help
```

If you don't have the AWS CLI installed, see [Installing the AWS Command Line Interface](#) in the *AWS CLI User Guide* for information about installing it.

Retrieving time-series metrics

The `GetResourceMetrics` operation retrieves one or more time-series metrics from the Performance Insights data. `GetResourceMetrics` requires a metric and time period, and returns a response with a list of data points.

For example, the AWS Management Console uses `GetResourceMetrics` to populate the **Counter Metrics** chart and the **Database Load** chart, as seen in the following image.

All metrics returned by `GetResourceMetrics` are standard time-series metrics, with the exception of `db.load`. This metric is displayed in the **Database Load** chart. The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called *dimensions*. In the previous image, `db.load` is broken down and grouped by the waits states that make up the `db.load`.

Note

`GetResourceMetrics` can also return the `db.sampleload` metric, but the `db.load` metric is appropriate in most cases.

For information about the counter metrics returned by `GetResourceMetrics`, see [Performance Insights counter metrics \(p. 618\)](#).

The following calculations are supported for the metrics:

- Average – The average value for the metric over a period of time. Append `.avg` to the metric name.
- Minimum – The minimum value for the metric over a period of time. Append `.min` to the metric name.
- Maximum – The maximum value for the metric over a period of time. Append `.max` to the metric name.
- Sum – The sum of the metric values over a period of time. Append `.sum` to the metric name.
- Sample count – The number of times the metric was collected over a period of time. Append `.sample_count` to the metric name.

For example, assume that a metric is collected for 300 seconds (5 minutes), and that the metric is collected one time each minute. The values for each minute are 1, 2, 3, 4, and 5. In this case, the following calculations are returned:

- Average – 3
- Minimum – 1
- Maximum – 5
- Sum – 15
- Sample count – 5

For information about using the `get-resource-metrics` AWS CLI command, see [get-resource-metrics](#).

For the `--metric-queries` option, specify one or more queries that you want to get results for. Each query consists of a mandatory `Metric` and optional `GroupBy` and `Filter` parameters. The following is an example of a `--metric-queries` option specification.

```
{  
    "Metric": "string",  
    "GroupBy": {  
        "Group": "string",  
        "Dimensions": ["string", ...],  
        "Limit": integer  
    },  
    "Filter": {"string": "string"  
    ...}
```

AWS CLI examples for Performance Insights

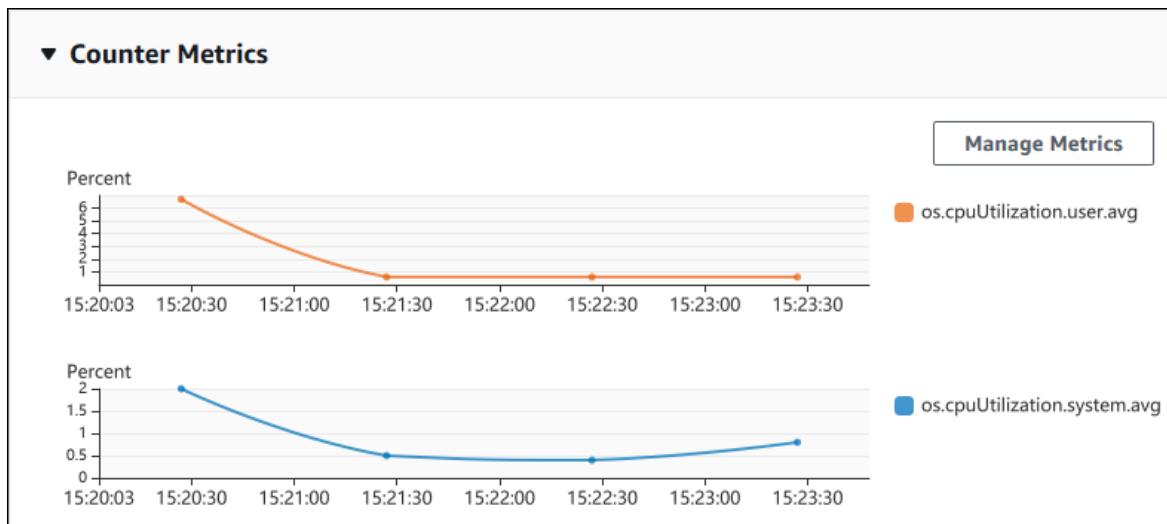

The following examples show how to use the AWS CLI for Performance Insights.

Topics

- [Retrieving counter metrics \(p. 587\)](#)
- [Retrieving the DB load average for top wait events \(p. 590\)](#)
- [Retrieving the DB load average for top SQL \(p. 592\)](#)
- [Retrieving the DB load average filtered by SQL \(p. 594\)](#)
- [Retrieving the full text of a SQL statement \(p. 597\)](#)

Retrieving counter metrics

The following screenshot shows two counter metrics charts in the AWS Management Console.

The following example shows how to gather the same data that the AWS Management Console uses to generate the two counter metric charts.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
--service-type RDS \
--identifier db-ID \
--start-time 2018-10-30T00:00:00Z \
--end-time 2018-10-30T01:00:00Z \
--period-in-seconds 60 \
--metric-queries '[{"Metric": "os.cpuUtilization.user.avg"}, {"Metric": "os.cpuUtilization.idle.avg"}]'
```

For Windows:

```
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-30T00:00:00Z ^
--end-time 2018-10-30T01:00:00Z ^
--period-in-seconds 60 ^
--metric-queries '[{"Metric": "os.cpuUtilization.user.avg"}, {"Metric": "os.cpuUtilization.idle.avg"}]'
```

You can also make a command easier to read by specifying a file for the `--metrics-query` option. The following example uses a file called `query.json` for the option. The file has the following contents.

```
[  
  {  
    "Metric": "os.cpuUtilization.user.avg"  
  },  
  {  
    "Metric": "os.cpuUtilization.idle.avg"  
  }]
```

Run the following command to use the file.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
--service-type RDS \
--identifier db-ID \
--start-time 2018-10-30T00:00:00Z \
--end-time 2018-10-30T01:00:00Z \
--period-in-seconds 60 \
--metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-30T00:00:00Z ^
--end-time 2018-10-30T01:00:00Z ^
--period-in-seconds 60 ^
--metric-queries file://query.json
```

The preceding example specifies the following values for the options:

- **--service-type** – RDS for Amazon RDS
- **--identifier** – The resource ID for the DB instance
- **--start-time** and **--end-time** – The ISO 8601 DateTime values for the period to query, with multiple supported formats

It queries for a one-hour time range:

- **--period-in-seconds** – 60 for a per-minute query
- **--metric-queries** – An array of two queries, each just for one metric.

The metric name uses dots to classify the metric in a useful category, with the final element being a function. In the example, the function is avg for each query. As with Amazon CloudWatch, the supported functions are min, max, total, and avg.

The response looks similar to the following.

```
{
  "Identifier": "db-XXX",
  "AlignedStartTime": 1540857600.0,
  "AlignedEndTime": 1540861200.0,
  "MetricList": [
    { //A list of key/datapoints
      "Key": {
        "Metric": "os.cpuUtilization.user.avg" //Metric1
      },
      "DataPoints": [
        //Each list of datapoints has the same timestamps and same number of items
        {
          "Timestamp": 1540857660.0, //Minute1
          "Value": 4.0
        },
        {
          "Timestamp": 1540857720.0, //Minute2
          "Value": 4.0
        },
        {
          "Timestamp": 1540857780.0, //Minute 3
          "Value": 10.0
        }
      ]
    }
  ]
}
```

```

        }
        //... 60 datapoints for the os.cpuUtilization.user.avg metric
    ],
    {
        "Key": {
            "Metric": "os.cpuUtilization.idle.avg" //Metric2
        },
        "DataPoints": [
            {
                "Timestamp": 1540857660.0, //Minute1
                "Value": 12.0
            },
            {
                "Timestamp": 1540857720.0, //Minute2
                "Value": 13.5
            },
            //... 60 datapoints for the os.cpuUtilization.idle.avg metric
        ]
    }
] //end of MetricList
} //end of response

```

The response has an `Identifier`, `AlignedStartTime`, and `AlignedEndTime`. Because the `--period-in-seconds` value was 60, the start and end times have been aligned to the minute. If the `--period-in-seconds` was 3600, the start and end times would have been aligned to the hour.

The `MetricList` in the response has a number of entries, each with a `Key` and a `DataPoints` entry. Each `DataPoint` has a `Timestamp` and a `Value`. Each `DataPoints` list has 60 data points because the queries are for per-minute data over an hour, with `Timestamp1/Minute1`, `Timestamp2/Minute2`, and so on, up to `Timestamp60/Minute60`.

Because the query is for two different counter metrics, there are two elements in the response `MetricList`.

Retrieving the DB load average for top wait events

The following example is the same query that the AWS Management Console uses to generate a stacked area line graph. This example retrieves the `db.load.avg` for the last hour with load divided according to the top seven wait events. The command is the same as the command in [Retrieving counter metrics \(p. 587\)](#). However, the `query.json` file has the following contents.

```
[
    {
        "Metric": "db.load.avg",
        "GroupBy": { "Group": "db.wait_event", "Limit": 7 }
    }
]
```

Run the following command.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
--service-type RDS \
--identifier db-ID \
--start-time 2018-10-30T00:00:00Z \
--end-time 2018-10-30T01:00:00Z \
--period-in-seconds 60 \
--metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-30T00:00:00Z ^
--end-time 2018-10-30T01:00:00Z ^
--period-in-seconds 60 ^
--metric-queries file://query.json
```

The example specifies the metric of db.load.avg and a GroupBy of the top seven wait events. For details about valid values for this example, see [DimensionGroup](#) in the *Performance Insights API Reference*.

The response looks similar to the following.

```
{
    "Identifier": "db-XXX",
    "AlignedStartTime": 1540857600.0,
    "AlignedEndTime": 1540861200.0,
    "MetricList": [
        { //A list of key/datapoints
            "Key": {
                //A Metric with no dimensions. This is the total db.load.avg
                "Metric": "db.load.avg"
            },
            "DataPoints": [
                //Each list of datapoints has the same timestamps and same number of items
                {
                    "Timestamp": 1540857660.0, //Minute1
                    "Value": 0.5166666666666667
                },
                {
                    "Timestamp": 1540857720.0, //Minute2
                    "Value": 0.3833333333333336
                },
                {
                    "Timestamp": 1540857780.0, //Minute 3
                    "Value": 0.2666666666666666
                }
                //... 60 datapoints for the total db.load.avg key
            ]
        },
        {
            "Key": {
                //Another key. This is db.load.avg broken down by CPU
                "Metric": "db.load.avg",
                "Dimensions": {
                    "db.wait_event.name": "CPU",
                    "db.wait_event.type": "CPU"
                }
            },
            "DataPoints": [
                {
                    "Timestamp": 1540857660.0, //Minute1
                    "Value": 0.35
                },
                {
                    "Timestamp": 1540857720.0, //Minute2
                    "Value": 0.15
                },
                //... 60 datapoints for the CPU key
            ]
        },
    ],
}
```

```
//... In total we have 8 key/datapoints entries, 1) total, 2-8) Top Wait Events
] //end of MetricList
} //end of response
```

In this response, there are eight entries in the MetricList. There is one entry for the total db.load.avg, and seven entries each for the db.load.avg divided according to one of the top seven wait events. Unlike in the first example, because there was a grouping dimension, there must be one key for each grouping of the metric. There can't be only one key for each metric, as in the basic counter metric use case.

Retrieving the DB load average for top SQL

The following example groups db.wait_events by the top 10 SQL statements. There are two different groups for SQL statements:

- db.sql – The full SQL statement, such as `select * from customers where customer_id = 123`
- db.sql_tokenized – The tokenized SQL statement, such as `select * from customers where customer_id = ?`

When analyzing database performance, it can be useful to consider SQL statements that only differ by their parameters as one logic item. So, you can use db.sql_tokenized when querying. However, especially when you're interested in explain plans, sometimes it's more useful to examine full SQL statements with parameters, and query grouping by db.sql. There is a parent-child relationship between tokenized and full SQL, with multiple full SQL (children) grouped under the same tokenized SQL (parent).

The command in this example is the similar to the command in [Retrieving the DB load average for top wait events \(p. 590\)](#). However, the query.json file has the following contents.

```
[  
  {  
    "Metric": "db.load.avg",  
    "GroupBy": { "Group": "db.sql_tokenized", "Limit": 10 }  
  }  
]
```

The following example uses db.sql_tokenized.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \  
  --service-type RDS \  
  --identifier db-ID \  
  --start-time 2018-10-29T00:00:00Z \  
  --end-time 2018-10-30T00:00:00Z \  
  --period-in-seconds 3600 \  
  --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^  
  --service-type RDS ^  
  --identifier db-ID ^  
  --start-time 2018-10-29T00:00:00Z ^  
  --end-time 2018-10-30T00:00:00Z ^
```

```
--period-in-seconds 3600 ^
--metric-queries file:///query.json
```

This example queries over 24 hours, with a one hour period-in-seconds.

The example specifies the metric of db.load.avg and a GroupBy of the top seven wait events. For details about valid values for this example, see [DimensionGroup](#) in the *Performance Insights API Reference*.

The response looks similar to the following.

```
{
    "AlignedStartTime": 1540771200.0,
    "AlignedEndTime": 1540857600.0,
    "Identifier": "db-XXX",

    "MetricList": [ //11 entries in the MetricList
        {
            "Key": { //First key is total
                "Metric": "db.load.avg"
            }
            "DataPoints": [ //Each DataPoints list has 24 per-hour Timestamps and a value
                {
                    "Value": 1.6964980544747081,
                    "Timestamp": 1540774800.0
                },
                //... 24 datapoints
            ]
        },
        {
            "Key": { //Next key is the top tokenized SQL
                "Dimensions": {
                    "db.sql_tokenized.statement": "INSERT INTO authors (id,name,email)
VALUES\n( nextval(?) ,?,?)",
                    "db.sql_tokenized.db_id": "pi-2372568224",
                    "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE"
                },
                "Metric": "db.load.avg"
            },
            "DataPoints": [ //... 24 datapoints
            ]
        },
        // In total 11 entries, 10 Keys of top tokenized SQL, 1 total key
    ] //End of MetricList
} //End of response
```

This response has 11 entries in the MetricList (1 total, 10 top tokenized SQL), with each entry having 24 per-hour DataPoints.

For tokenized SQL, there are three entries in each dimensions list:

- db.sql_tokenized.statement – The tokenized SQL statement.
- db.sql_tokenized.db_id – Either the native database ID used to refer to the SQL, or a synthetic ID that Performance Insights generates for you if the native database ID isn't available. This example returns the pi-2372568224 synthetic ID.
- db.sql_tokenized.id – The ID of the query inside Performance Insights.

In the AWS Management Console, this ID is called the Support ID. It's named this because the ID is data that AWS Support can examine to help you troubleshoot an issue with your database. AWS takes the security and privacy of your data extremely seriously, and almost all data is stored encrypted with your AWS KMS customer master key (CMK). Therefore, nobody inside AWS can look at this data. In

In the example preceding, both the `tokenized.statement` and the `tokenized.db_id` are stored encrypted. If you have an issue with your database, AWS Support can help you by referencing the Support ID.

When querying, it might be convenient to specify a Group in `GroupBy`. However, for finer-grained control over the data that's returned, specify the list of dimensions. For example, if all that is needed is the `db.sql_tokenized.statement`, then a `Dimensions` attribute can be added to the `query.json` file.

```
[  
  {  
    "Metric": "db.load.avg",  
    "GroupBy": {  
      "Group": "db.sql_tokenized",  
      "Dimensions": ["db.sql_tokenized.statement"],  
      "Limit": 10  
    }  
  }  
]
```

Retrieving the DB load average filtered by SQL

The preceding image shows that a particular query is selected, and the top average active sessions stacked area line graph is scoped to that query. Although the query is still for the top seven overall wait events, the value of the response is filtered. The filter causes it to take into account only sessions that are a match for the particular filter.

The corresponding API query in this example is similar to the command in [Retrieving the DB load average for top SQL \(p. 592\)](#). However, the `query.json` file has the following contents.

```
[  
  {  
    "Metric": "db.load.avg",  
    "GroupBy": { "Group": "db.wait_event", "Limit": 5 },  
    "Filter": { "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE" }  
}
```

]

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
--service-type RDS \
--identifier db-ID \
--start-time 2018-10-30T00:00:00Z \
--end-time 2018-10-30T01:00:00Z \
--period-in-seconds 60 \
--metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-30T00:00:00Z ^
--end-time 2018-10-30T01:00:00Z ^
--period-in-seconds 60 ^
--metric-queries file://query.json
```

The response looks similar to the following.

```
{
    "Identifier": "db-XXX",
    "AlignedStartTime": 1556215200.0,
    "MetricList": [
        {
            "Key": {
                "Metric": "db.load.avg"
            },
            "DataPoints": [
                {
                    "Timestamp": 1556218800.0,
                    "Value": 1.4878117913832196
                },
                {
                    "Timestamp": 1556222400.0,
                    "Value": 1.192823803967328
                }
            ]
        },
        {
            "Key": {
                "Metric": "db.load.avg",
                "Dimensions": {
                    "db.wait_event.type": "io",
                    "db.wait_event.name": "wait/io/aurora_redo_log_flush"
                }
            },
            "DataPoints": [
                {
                    "Timestamp": 1556218800.0,

                },
                {
                    "Timestamp": 1556222400.0,
                    "Value": 1.058051341890315
                }
            ]
        },
    ],
}
```

```
{
    "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
            "db.wait_event.type": "io",
            "db.wait_event.name": "wait/io/table/sql/handler"
        }
    },
    "DataPoints": [
        {
            "Timestamp": 1556218800.0,
            "Value": 0.16241496598639457
        },
        {
            "Timestamp": 1556222400.0,
            "Value": 0.05163360560093349
        }
    ]
},
{
    "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
            "db.wait_event.type": "synch",
            "db.wait_event.name": "wait/synch/mutex/innodb/aurora_lock_thread_slot_futex"
        }
    },
    "DataPoints": [
        {
            "Timestamp": 1556218800.0,
            "Value": 0.11479591836734694
        },
        {
            "Timestamp": 1556222400.0,
            "Value": 0.013127187864644107
        }
    ]
},
{
    "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
            "db.wait_event.type": "CPU",
            "db.wait_event.name": "CPU"
        }
    },
    "DataPoints": [
        {
            "Timestamp": 1556218800.0,
            "Value": 0.05215419501133787
        },
        {
            "Timestamp": 1556222400.0,
            "Value": 0.05805134189031505
        }
    ]
},
{
    "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
            "db.wait_event.type": "synch",
            "db.wait_event.name": "wait/synch/mutex/innodb/lock_wait_mutex"
        }
    },
}
```

```

    "DataPoints": [
      {
        "Timestamp": 1556218800.0,
        "Value": 0.017573696145124718
      },
      {
        "Timestamp": 1556222400.0,
        "Value": 0.002333722287047841
      }
    ]
  ],
  "AlignedEndTime": 1556222400.0
} //end of response

```

In this response, all values are filtered according to the contribution of tokenized SQL AKIAIOSFODNN7EXAMPLE specified in the query.json file. The keys also might follow a different order than a query without a filter, because it's the top five wait events that affected the filtered SQL.

Retrieving the full text of a SQL statement

The following example retrieves the full text of a SQL statement for DB instance db-10BCD2EFGHIJ3KL4M5N06PQRS5. The --group is db.sql, and the --group-identifier is db.sql.id. In this example, *my-sql-id* represents a SQL ID retrieved by invoking pi get-resource-metrics or pi describe-dimension-keys.

Run the following command.

For Linux, macOS, or Unix:

```

aws pi get-dimension-key-details \
--service-type RDS \
--identifier db-10BCD2EFGHIJ3KL4M5N06PQRS5 \
--group db.sql \
--group-identifier my-sql-id \
--requested-dimensions statement

```

For Windows:

```

aws pi get-dimension-key-details ^
--service-type RDS ^
--identifier db-10BCD2EFGHIJ3KL4M5N06PQRS5 ^
--group db.sql ^
--group-identifier my-sql-id ^
--requested-dimensions statement

```

In this example, the dimensions details are available. Thus, Performance Insights retrieves the full text of the SQL statement, without truncating it.

```

{
  "Dimensions": [
    {
      "Value": "SELECT e.last_name, d.department_name FROM employees e, departments d
WHERE e.department_id=d.department_id",
      "Dimension": "db.sql.statement",
      "Status": "AVAILABLE"
    },
    ...
  ]
}

```

}

Logging Performance Insights calls using AWS CloudTrail

Performance Insights runs with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Performance Insights. CloudTrail captures all API calls for Performance Insights as events. This capture includes calls from the Amazon RDS console and from code calls to the Performance Insights API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Performance Insights. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the data collected by CloudTrail, you can determine certain information. This information includes the request that was made to Performance Insights, the IP address the request was made from, who made the request, and when it was made. It also includes additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](#).

Working with Performance Insights information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Performance Insights, that activity is recorded in a CloudTrail event along with other AWS service events in the CloudTrail console in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#) in *AWS CloudTrail User Guide*.

For an ongoing record of events in your AWS account, including events for Performance Insights, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in *AWS CloudTrail User Guide*:

- [Overview for Creating a Trail](#)
- [CloudTrail Supported Services and Integrations](#)
- [Configuring Amazon SNS Notifications for CloudTrail](#)
- [Receiving CloudTrail Log Files from Multiple Regions](#) and [Receiving CloudTrail Log Files from Multiple Accounts](#)

All Performance Insights operations are logged by CloudTrail and are documented in the [Performance Insights API Reference](#). For example, calls to the `DescribeDimensionKeys` and `GetResourceMetrics` operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentity Element](#).

Performance Insights log file entries

A *trail* is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An *event* represents a single request from any source. Each event includes information about the requested operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `GetResourceMetrics` operation.

```
{  
    "eventVersion": "1.05",  
    "userIdentity": {  
        "type": "IAMUser",  
        "principalId": "AKIAIOSFODNN7EXAMPLE",  
        "arn": "arn:aws:iam::123456789012:user/johndoe",  
        "accountId": "123456789012",  
        "accessKeyId": "AKIAI44QH8DHBEXAMPLE",

Monitoring OS metrics with Enhanced Monitoring

With Enhanced Monitoring, you can monitor the operating system of your DB instance in real time. When you want to see how different processes or threads use the CPU, Enhanced Monitoring metrics are useful.

Topics

- [Overview of Enhanced Monitoring \(p. 600\)](#)
- [Setting up and enabling Enhanced Monitoring \(p. 601\)](#)
- [Viewing OS metrics in the RDS console \(p. 605\)](#)
- [Viewing OS metrics using CloudWatch Logs \(p. 608\)](#)

Overview of Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view all the system metrics and process information for your RDS DB instances on the console. You can manage which metrics you want to monitor for each instance and customize the dashboard according to your requirements. For descriptions of the Enhanced Monitoring metrics, see [OS metrics in Enhanced Monitoring \(p. 633\)](#).

RDS delivers the metrics from Enhanced Monitoring into your Amazon CloudWatch Logs account. You can create metrics filters in CloudWatch from CloudWatch Logs and display the graphs on the CloudWatch dashboard. You can consume the Enhanced Monitoring JSON output from CloudWatch Logs in a monitoring system of your choice. For more information, see [Enhanced Monitoring](#) in the Amazon RDS FAQs.

Topics

- [Enhanced Monitoring availability \(p. 600\)](#)
- [Differences between CloudWatch and Enhanced Monitoring metrics \(p. 600\)](#)
- [Retention of Enhanced Monitoring metrics \(p. 601\)](#)
- [Cost of Enhanced Monitoring \(p. 601\)](#)

Enhanced Monitoring availability

Enhanced Monitoring is available for the following database engines:

- MariaDB
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL

Enhanced Monitoring is available for all DB instance classes except for the db.m1.small instance class.

Differences between CloudWatch and Enhanced Monitoring metrics

A *hypervisor* creates and runs virtual machines (VMs). Using a hypervisor, an instance can support multiple guest VMs by virtually sharing memory and CPU. CloudWatch gathers metrics about CPU

utilization from the hypervisor for a DB instance. In contrast, Enhanced Monitoring gathers its metrics from an agent on the DB instance.

You might find differences between the CloudWatch and Enhanced Monitoring measurements, because the hypervisor layer performs a small amount of work. The differences can be greater if your DB instances use smaller instance classes. In this scenario, more virtual machines (VMs) are probably managed by the hypervisor layer on a single physical instance.

For descriptions of the Enhanced Monitoring metrics, see [OS metrics in Enhanced Monitoring \(p. 633\)](#). For more information about CloudWatch metrics, see the [Amazon CloudWatch User Guide](#).

Retention of Enhanced Monitoring metrics

By default, Enhanced Monitoring metrics are stored for 30 days in the CloudWatch Logs. This retention period is different from typical CloudWatch metrics.

To modify the amount of time the metrics are stored in the CloudWatch Logs, change the retention for the RDSOSMetrics log group in the CloudWatch console. For more information, see [Change log data retention in CloudWatch logs](#) in the *Amazon CloudWatch Logs User Guide*.

Cost of Enhanced Monitoring

Enhanced Monitoring metrics are stored in the CloudWatch Logs instead of in CloudWatch metrics. The cost of Enhanced Monitoring depends on the following factors:

- You are charged for Enhanced Monitoring only if you exceed the free tier provided by Amazon CloudWatch Logs. Charges are based on CloudWatch Logs data transfer and storage rates.
- The amount of information transferred for an RDS instance is directly proportional to the defined granularity for the Enhanced Monitoring feature. A smaller monitoring interval results in more frequent reporting of OS metrics and increases your monitoring cost. To manage costs, set different granularities for different instances in your accounts.
- Usage costs for Enhanced Monitoring are applied for each DB instance that Enhanced Monitoring is enabled for. Monitoring a large number of DB instances is more expensive than monitoring only a few.
- DB instances that support a more compute-intensive workload have more OS process activity to report and higher costs for Enhanced Monitoring.

For more information about pricing, see [Amazon CloudWatch pricing](#).

Setting up and enabling Enhanced Monitoring

To use Enhanced Monitoring, you must create an IAM role, and then enable Enhanced Monitoring.

Topics

- [Creating an IAM role for Enhanced Monitoring \(p. 601\)](#)
- [Turning Enhanced Monitoring on and off \(p. 602\)](#)
- [Protecting against the confused deputy problem \(p. 604\)](#)

Creating an IAM role for Enhanced Monitoring

Enhanced Monitoring requires permission to act on your behalf to send OS metric information to CloudWatch Logs. You grant Enhanced Monitoring permissions using an AWS Identity and Access Management (IAM) role. You can either create this role when you enable Enhanced Monitoring or create it beforehand.

Topics

- [Creating the IAM role when you enable Enhanced Monitoring \(p. 602\)](#)
- [Creating the IAM role before you enable Enhanced Monitoring \(p. 602\)](#)

Creating the IAM role when you enable Enhanced Monitoring

When you enable Enhanced Monitoring in the RDS console, Amazon RDS can create the required IAM role for you. The role is named `rds-monitoring-role`. RDS uses this role for the specified DB instance, read replica, or Multi-AZ DB cluster.

To create the IAM role when enabling Enhanced Monitoring

1. Follow the steps in [Turning Enhanced Monitoring on and off \(p. 602\)](#).
2. Set **Monitoring Role** to **Default** in the step where you choose a role.

Creating the IAM role before you enable Enhanced Monitoring

You can create the required role before you enable Enhanced Monitoring. When you enable Enhanced Monitoring, specify your new role's name. You must create this required role if you enable Enhanced Monitoring using the AWS CLI or the RDS API.

The user that enables Enhanced Monitoring must be granted the `PassRole` permission. For more information, see Example 2 in [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

To create an IAM role for Amazon RDS enhanced monitoring

1. Open the [IAM console](#) at <https://console.aws.amazon.com>.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Choose the **AWS service** tab, and then choose **RDS** from the list of services.
5. Choose **RDS - Enhanced Monitoring**, and then choose **Next**.
6. Ensure that the **Permissions policies** shows **AmazonRDSEnhancedMonitoringRole**, and then choose **Next**.
7. For **Role name**, enter a name for your role. For example, enter `emaccess`.

The trusted entity for your role is the AWS service `monitoring.rds.amazonaws.com`.

8. Choose **Create role**.

Turning Enhanced Monitoring on and off

You can turn Enhanced Monitoring on and off using the AWS Management Console, AWS CLI, or RDS API. You choose the RDS DB instances on which you want to turn on Enhanced Monitoring. You can set different granularities for metric collection on each DB instance.

Console

You can turn on Enhanced Monitoring when you create a DB instance, Multi-AZ DB cluster, or read replica, or when you modify a DB instance or Multi-AZ DB cluster. If you modify a DB instance to turn on Enhanced Monitoring, you don't need to reboot your DB instance for the change to take effect.

You can turn on Enhanced Monitoring in the RDS console when you do one of the following actions in the **Databases** page:

- **Create a DB instance or Multi-AZ DB cluster** – Choose **Create database**.
- **Create a read replica** – Choose **Actions**, then **Create read replica**.
- **Modify a DB instance or Multi-AZ DB cluster** – Choose **Modify**.

To turn Enhanced Monitoring on or off in the RDS console

1. Scroll to **Additional configuration**.
2. In **Monitoring**, choose **Enable Enhanced Monitoring** for your DB instance or read replica. To turn Enhanced Monitoring off, choose **Disable Enhanced Monitoring**.
3. Set the **Monitoring Role** property to the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose **Default** to have RDS create a role for you named `rds-monitoring-role`.
4. Set the **Granularity** property to the interval, in seconds, between points when metrics are collected for your DB instance or read replica. The **Granularity** property can be set to one of the following values: 1, 5, 10, 15, 30, or 60.

The fastest that the RDS console refreshes is every 5 seconds. If you set the granularity to 1 second in the RDS console, you still see updated metrics only every 5 seconds. You can retrieve 1-second metric updates by using CloudWatch Logs.

AWS CLI

To turn on Enhanced Monitoring using the AWS CLI, in the following commands, set the `--monitoring-interval` option to a value other than 0 and set the `--monitoring-role-arn` option to the role you created in [Creating an IAM role for Enhanced Monitoring \(p. 601\)](#).

- [create-db-instance](#)
- [create-db-instance-read-replica](#)
- [modify-db-instance](#)
- [create-db-cluster](#) (Multi-AZ DB cluster)
- [modify-db-cluster](#) (Multi-AZ DB cluster)

The `--monitoring-interval` option specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values for the option are 0, 1, 5, 10, 15, 30, and 60.

To turn off Enhanced Monitoring using the AWS CLI, set the `--monitoring-interval` option to 0 in these commands.

Example

The following example turns on Enhanced Monitoring for a DB instance:

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --monitoring-interval 30 \
  --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```
aws rds modify-db-instance ^
```

```
--db-instance-identifier mydbinstance ^
--monitoring-interval 30 ^
--monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

Example

The following example turns on Enhanced Monitoring for a Multi-AZ DB cluster:

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
--db-cluster-identifier mydbcluster \
--monitoring-interval 30 \
--monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```
aws rds modify-db-cluster ^
--db-cluster-identifier mydbcluster ^
--monitoring-interval 30 ^
--monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

RDS API

To turn on Enhanced Monitoring using the RDS API, set the `MonitoringInterval` parameter to a value other than `0` and set the `MonitoringRoleArn` parameter to the role you created in [Creating an IAM role for Enhanced Monitoring \(p. 601\)](#). Set these parameters in the following actions:

- [CreateDBInstance](#)
- [CreateDBInstanceReadReplica](#)
- [ModifyDBInstance](#)
- [CreateDBCluster \(Multi-AZ DB cluster\)](#)
- [ModifyDBCluster \(Multi-AZ DB cluster\)](#)

The `MonitoringInterval` parameter specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values are `0`, `1`, `5`, `10`, `15`, `30`, and `60`.

To turn off Enhanced Monitoring using the RDS API, set `MonitoringInterval` to `0`.

Protecting against the confused deputy problem

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see [The confused deputy problem](#).

To limit the permissions to the resource that Amazon RDS can give another service, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in a trust policy for your Enhanced Monitoring role. If you use both global condition context keys, they must use the same account ID.

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. For Amazon RDS, set `aws:SourceArn` to `arn:aws:rds:Region:my-account-id:db:dbname`.

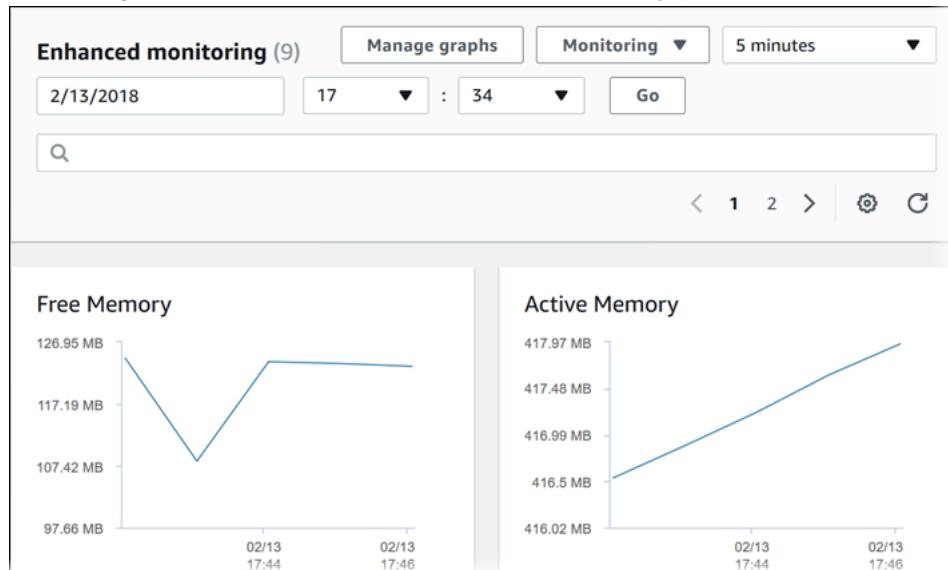

The following example uses the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in a trust policy to prevent the confused deputy problem.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "rds.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole",  
            "Condition": {  
                "StringLike": {  
                    "aws:SourceArn": "arn:aws:rds:Region:my-account-id:db:dbname"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "my-account-id"  
                }  
            }  
        }  
    ]  
}
```

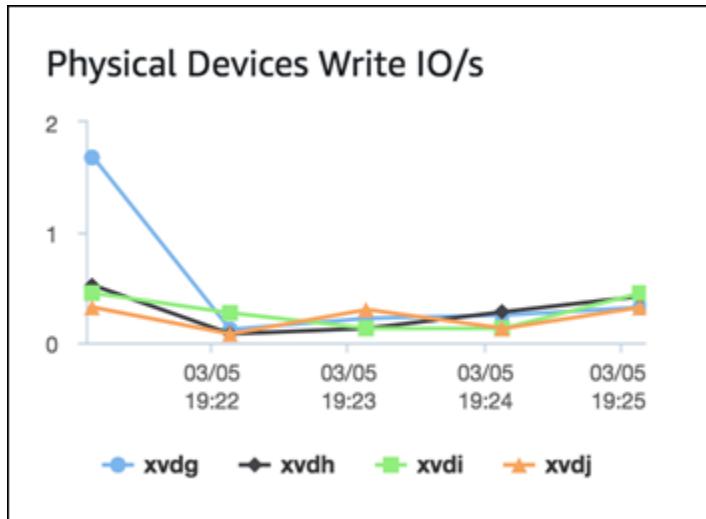

Viewing OS metrics in the RDS console

You can view OS metrics reported by Enhanced Monitoring in the RDS console by choosing **Enhanced monitoring for Monitoring**.

The following example shows the Enhanced Monitoring page. For descriptions of the Enhanced Monitoring metrics, see [OS metrics in Enhanced Monitoring \(p. 633\)](#).

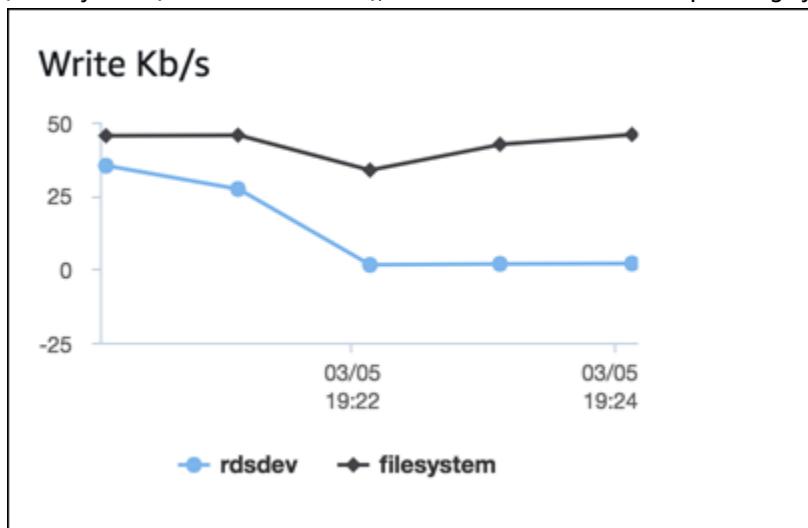

Some DB instances use more than one disk for the DB instance's data storage volume. On those DB instances, the **Physical Devices** graphs show metrics for each one of the disks. For example, the following graph shows metrics for four disks.

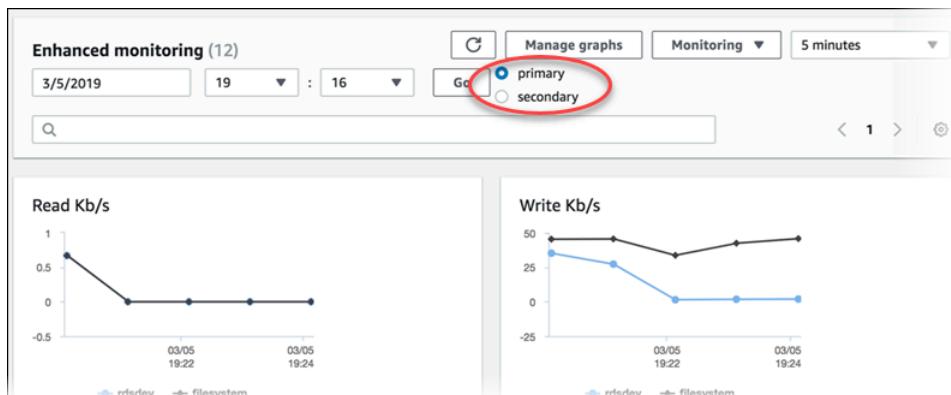

Note

Currently, **Physical Devices** graphs are not available for Microsoft SQL Server DB instances.

When you are viewing aggregated **Disk I/O** and **File system** graphs, the **rdsdev** device relates to the **/rdsdbdata** file system, where all database files and logs are stored. The **filesystem** device relates to the **/** file system (also known as root), where files related to the operating system are stored.

If the DB instance is a Multi-AZ deployment, you can view the OS metrics for the primary DB instance and its Multi-AZ standby replica. In the **Enhanced monitoring** view, choose **primary** to view the OS metrics for the primary DB instance, or choose **secondary** to view the OS metrics for the standby replica.

For more information about Multi-AZ deployments, see [Multi-AZ deployments for high availability \(p. 121\)](#).

Note

Currently, viewing OS metrics for a Multi-AZ standby replica is not supported for MariaDB or Microsoft SQL Server DB instances.

If you want to see details for the processes running on your DB instance, choose **OS process list** for **Monitoring**.

The **Process List** view is shown following.

Process List						
<input type="text"/> Filter process list						
NAME	VIRT	RES	CPU%	MEM%	VMLIMIT	
postgres [3181] ^t	283.55 MB	17.11 MB	0.02	1.72		
postgres: rdsadmin rdsadmin localhost(40156) idle [2953] ^t	384.7 MB	9.51 MB	0.02	0.95		

The Enhanced Monitoring metrics shown in the **Process list** view are organized as follows:

- **RDS child processes** – Shows a summary of the RDS processes that support the DB instance, for example mysqld for MySQL DB instances. Process threads appear nested beneath the parent process. Process threads show CPU utilization only as other metrics are the same for all threads for the process. The console displays a maximum of 100 processes and threads. The results are a combination of the top CPU consuming and memory consuming processes and threads. If there are more than 50 processes and more than 50 threads, the console displays the top 50 consumers in each category. This display helps you identify which processes are having the greatest impact on performance.
- **RDS processes** – Shows a summary of the resources used by the RDS management agent, diagnostics monitoring processes, and other AWS processes that are required to support RDS DB instances.
- **OS processes** – Shows a summary of the kernel and system processes, which generally have minimal impact on performance.

The items listed for each process are:

- **VIRT** – Displays the virtual size of the process.
- **RES** – Displays the actual physical memory being used by the process.
- **CPU%** – Displays the percentage of the total CPU bandwidth being used by the process.
- **MEM%** – Displays the percentage of the total memory being used by the process.

The monitoring data that is shown in the RDS console is retrieved from Amazon CloudWatch Logs. You can also retrieve the metrics for a DB instance as a log stream from CloudWatch Logs. For more information, see [Viewing OS metrics using CloudWatch Logs \(p. 608\)](#).

Enhanced Monitoring metrics are not returned during the following:

- A failover of the DB instance.
- Changing the instance class of the DB instance (scale compute).

Enhanced Monitoring metrics are returned during a reboot of a DB instance because only the database engine is rebooted. Metrics for the operating system are still reported.

Viewing OS metrics using CloudWatch Logs

After you have enabled Enhanced Monitoring for your DB instance or Multi-AZ DB cluster, you can view the metrics for it using CloudWatch Logs, with each log stream representing a single DB instance or DB cluster being monitored. The log stream identifier is the resource identifier (`DbiResourceId`) for the DB instance or DB cluster.

To view Enhanced Monitoring log data

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. If necessary, choose the AWS Region that your DB instance or Multi-AZ DB cluster is in. For more information, see [Regions and endpoints](#) in the *Amazon Web Services General Reference*.
3. Choose **Logs** in the navigation pane.
4. Choose **RDSOSMetrics** from the list of log groups.

In a Multi-AZ DB instance deployment, log files with `-secondary` appended to the name are for the Multi-AZ standby replica.

The screenshot shows the CloudWatch Log Groups interface. At the top, there are buttons for 'Search Log Group', 'Create Log Stream', and 'Delete Log Stream'. Below that is a 'Filter' input field set to 'Log Stream Name Prefix'. The main area displays a table of log streams. The first row has a checkbox and the text 'Log Streams'. The second row contains two entries: 'db-SORJBHOPBSMWGRI5EJW3KMYOTU-secondary' and 'db-SORJBHOPBSMWGRI5EJW3KMYOTU'. A red box highlights the secondary log stream. To the right of the streams, there is a column for 'Last Event Time' with values '2019-03-05 12:12 UTC-8' and '2019-03-05 12:07 UTC-8' respectively. Navigation arrows and a refresh icon are at the top right of the table area.

Log Streams	Last Event Time
db-SORJBHOPBSMWGRI5EJW3KMYOTU-secondary	2019-03-05 12:12 UTC-8
db-SORJBHOPBSMWGRI5EJW3KMYOTU	2019-03-05 12:07 UTC-8

5. Choose the log stream that you want to view from the list of log streams.

Metrics reference for Amazon RDS

In this reference, you can find descriptions of Amazon RDS metrics for Amazon CloudWatch, Performance Insights, and Enhanced Monitoring.

Amazon CloudWatch metrics for Amazon RDS

Amazon RDS publishes metrics to Amazon CloudWatch in the AWS/RDS and AWS/Usage namespaces.

Topics

- [Amazon CloudWatch instance-level metrics for Amazon RDS \(p. 609\)](#)
- [Amazon CloudWatch usage metrics for Amazon RDS \(p. 615\)](#)

Amazon CloudWatch instance-level metrics for Amazon RDS

The AWS/RDS namespace in Amazon CloudWatch includes the following instance-level metrics.

Note

The Amazon RDS console might display metrics in units that are different from the units sent to Amazon CloudWatch. For example, the Amazon RDS console might display a metric in megabytes (MB), while the metric is sent to Amazon CloudWatch in bytes.

Metric	Console name	Description	Units
BinLogDiskUsage	Binary Log Disk Usage (MB)	The amount of disk space occupied by binary logs. If automatic backups are enabled for MySQL and MariaDB instances, including read replicas, binary logs are created.	Bytes
BurstBalance	Burst Balance (Percent)	The percent of General Purpose SSD (gp2) burst-bucket I/O credits available.	Percent
CheckpointLag	Checkpoint Lag (Milliseconds)	The amount of time since the most recent checkpoint. Applies to only RDS for PostgreSQL.	Seconds
ConnectionAttempts	Connection Attempts (Count)	The number of attempts to connect to an instance, whether successful or not.	Count
CPUUtilization	CPU Utilization (Percent)	The percentage of CPU utilization.	Percent
CPUTCreditUsage	CPU Credit Usage (Count)	(T2 instances) The number of CPU credits spent by the instance for CPU utilization.	Credits (vCPU-minutes)

Metric	Console name	Description	Units
		<p>One CPU credit equals one vCPU running at 100 percent utilization for one minute or an equivalent combination of vCPUs, utilization, and time. For example, you might have one vCPU running at 50 percent utilization for two minutes or two vCPUs running at 25 percent utilization for two minutes.</p> <p>CPU credit metrics are available at a five-minute frequency only. If you specify a period greater than five minutes, use the Sum statistic instead of the Average statistic.</p>	
CPUCreditBalance	CPU Credit Balance (Count)	<p>(T2 instances) The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the CPUCreditBalance also includes the number of launch credits that have been accrued.</p> <p>Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits don't count towards the limit.</p> <p>The credits in the CPUCreditBalance are available for the instance to spend to burst beyond its baseline CPU utilization.</p> <p>When an instance is running, credits in the CPUCreditBalance don't expire. When the instance stops, the CPUCreditBalance does not persist, and all accrued credits are lost.</p> <p>CPU credit metrics are available at a five-minute frequency only.</p> <p>Launch credits work the same way in Amazon RDS as they do in Amazon EC2. For more information, see Launch credits in the <i>Amazon Elastic Compute Cloud User Guide for Linux Instances</i>.</p>	Credits (vCPU-minutes)

Metric	Console name	Description	Units
DatabaseConnections	DB Connections (Count)	<p>The number of client network connections to the database instance.</p> <p>The number of database sessions can be higher than the metric value because the metric value doesn't include the following:</p> <ul style="list-style-type: none"> • Sessions that no longer have a network connection but which the database hasn't cleaned up • Sessions created by the database engine for its own purposes • Sessions created by the database engine's parallel execution capabilities • Sessions created by the database engine job scheduler • Amazon RDS connections 	Count
DiskQueueDepth	Queue Depth (Count)	The number of outstanding I/Os (read/write requests) waiting to access the disk.	Count
EBSByteBalance %	EBS Byte Balance (Percent)	<p>The percentage of throughput credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only.</p> <p>The metric value is based on the throughput and IOPS of all volumes, including the root volume, rather than on only those volumes containing database files.</p> <p>To find the instance sizes that support this metric, see the instance sizes with an asterisk (*) in the EBS optimized by default table in <i>Amazon EC2 User Guide for Linux Instances</i>. The Sum statistic is not applicable to this metric.</p>	Percent

Metric	Console name	Description	Units
EBSIOBalance%	EBS IO Balance (Percent)	<p>The percentage of I/O credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only.</p> <p>The metric value is based on the throughput and IOPS of all volumes, including the root volume, rather than on only those volumes containing database files.</p> <p>To find the instance sizes that support this metric, see the instance sizes with an asterisk (*) in the EBS optimized by default table in <i>Amazon EC2 User Guide for Linux Instances</i>. The Sum statistic is not applicable to this metric.</p> <p>This metric is different from BurstBalance. To learn how to use this metric, see Improving application performance and reducing costs with Amazon EBS-Optimized Instance burst capability.</p>	Percent
FailedSQLServerJobs	Failed SQL Server Agent Jobs Count (Count/Minute)	The number of failed Microsoft SQL Server Agent jobs during the last minute.	Count/Minute
FreeableMemory	Freeable Memory (MB)	<p>The amount of available random access memory.</p> <p>For MariaDB, MySQL, Oracle, and PostgreSQL DB instances, this metric reports the value of the MemAvailable field of /proc/meminfo.</p>	Bytes
FreeLocalStorage	Free Local Storage (MB)	<p>The amount of available local storage space.</p> <p>This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.</p> <p>(This doesn't apply to Aurora Serverless v2.)</p>	Bytes

Metric	Console name	Description	Units
FreeStorageSpace	Free Storage Space (MB)	The amount of available storage space.	Bytes
MaximumUsedTransactionIDs	Maximum Used Transaction IDs (Count)	The maximum transaction IDs that have been used. Applies to only PostgreSQL.	Count
NetworkReceiveThroughput	Network Receive Throughput (MB/Second)	The incoming (receive) network traffic on the DB instance, including both customer database traffic and Amazon RDS traffic used for monitoring and replication.	Bytes/Second
NetworkTransmitThroughput	Network Transmit Throughput (MB/Second)	The outgoing (transmit) network traffic on the DB instance, including both customer database traffic and Amazon RDS traffic used for monitoring and replication.	Bytes/Second
OldestReplicationLag	Oldest Replication Lag (MB)	The lagging size of the replica lagging the most in terms of write-ahead log (WAL) data received. Applies to PostgreSQL.	Bytes
ReadIOPS	Read IOPS (Count/Second)	The average number of disk read I/O operations per second.	Count/Second
ReadIOPSLocalStorage	Read IOPS Local Storage (Count/Second)	<p>The average number of disk read I/O operations to local storage per second.</p> <p>This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.</p>	Count/Second
ReadLatency	Read Latency (Milliseconds)	The average amount of time taken per disk I/O operation.	Seconds
ReadLatencyLocalStorage	Read Latency Local Storage (Milliseconds)	<p>The average amount of time taken per disk I/O operation for local storage.</p> <p>This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.</p>	Seconds
ReadThroughput	Read Throughput (MB/Second)	The average number of bytes read from disk per second.	Bytes/Second

Metric	Console name	Description	Units
ReadThroughputLocalStorage	Read Throughput Local Storage (MB/Second)	The average number of bytes read from disk per second for local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes . The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.	Bytes/Second
ReplicaLag	Replica Lag (Milliseconds)	For read replica configurations, the amount of time a read replica DB instance lags behind the source DB instance. Applies to MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL read replicas. For Multi-AZ DB clusters, the difference in time between the latest transaction on the writer DB instance and the latest applied transaction on a reader DB instance.	Seconds
ReplicationSlotDiskUsage	Replica Slot Disk Usage (MB)	The disk space used by replication slot files. Applies to PostgreSQL.	Bytes
SwapUsage	Swap Usage (MB)	The amount of swap space used on the DB instance. This metric is not available for SQL Server.	Bytes
TransactionLogsDiskUsage	Transaction Logs Disk Usage (MB)	The disk space used by transaction logs. Applies to PostgreSQL.	Bytes
TransactionLogsGeneration	TransactionLogs Generation (MB/Second)	The size of transaction logs generated per second. Applies to PostgreSQL.	Bytes/Second
WriteIOPS	Write IOPS (Count/Second)	The average number of disk write I/O operations per second.	Count/Second

Metric	Console name	Description	Units
WriteIOPSLocalStorage	Write IOPS Local Storage (Count/Second)	The average number of disk write I/O operations per second on local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes . The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.	Count/Second
WriteLatency	Write Latency (Milliseconds)	The average amount of time taken per disk I/O operation.	Seconds
WriteLatencyLocalStorage	Write Latency Local Storage (Milliseconds)	The average amount of time taken per disk I/O operation on local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes . The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.	Milliseconds
WriteThroughput	Write Throughput (MB/Second)	The average number of bytes written to disk per second.	Bytes/Second
WriteThroughputLocalStorage	Write Storage Throughput Local Storage (MB/Second)	The average number of bytes written to disk per second for local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes . The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.	Bytes/Second

Amazon CloudWatch usage metrics for Amazon RDS

The AWS/Usage namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. CloudWatch collects usage metrics automatically for all AWS Regions.

For more information, see [CloudWatch usage metrics](#) in the *Amazon CloudWatch User Guide*. For more information about quotas, see [Quotas and constraints for Amazon RDS \(p. 2135\)](#) and [Requesting a quota increase](#) in the *Service Quotas User Guide*.

Metric	Description	Units*
AllocatedStorage	The total storage for all DB instances. The sum excludes temporary migration instances.	Gigabytes
DBClusterParameterGroups	The number of DB cluster parameter groups in your AWS account. The count excludes default parameter groups.	Count
DBClusters	The number of Amazon Aurora DB clusters in your AWS account.	Count
DBInstances	The number of DB instances in your AWS account.	Count
DBParameterGroups	The number of DB parameter groups in your AWS account. The count excludes the default DB parameter groups.	Count
DBSecurityGroups	The number of security groups in your AWS account. The count excludes the default security group and the default VPC security group.	Count
DBSubnetGroups	The number of DB subnet groups in your AWS account. The count excludes the default subnet group.	Count
ManualClusterSnapshots	The number of manually created DB cluster snapshots in your AWS account. The count excludes invalid snapshots.	Count
ManualSnapshots	The number of manually created DB snapshots in your AWS account. The count excludes invalid snapshots.	Count
OptionGroups	The number of option groups in your AWS account. The count excludes the default option groups.	Count
ReservedDBInstances	The number of reserved DB instances in your AWS account. The count excludes retired or declined instances.	Count

* Amazon RDS doesn't publish units for usage metrics to CloudWatch. The units only appear in the documentation.

Amazon CloudWatch dimensions for Amazon RDS

You can filter Amazon RDS metrics data by using any dimension in the following table.

Dimension	Filters the requested data for ...
DBInstanceIdentifier	A specific DB instance.
DatabaseClass	All instances in a database class. For example, you can aggregate metrics for all instances that belong to the database class db.r5.large.
EngineName	The identified engine name only. For example, you can aggregate metrics for all instances that have the engine name postgres.

Dimension	Filters the requested data for ...
SourceRegion	The specified Region only. For example, you can aggregate metrics for all DB instances in the us-east-1 Region.

Amazon CloudWatch metrics for Performance Insights

Performance Insights automatically publishes metrics to Amazon CloudWatch. The same data can be queried from Performance Insights, but having the metrics in CloudWatch makes it easy to add CloudWatch alarms. It also makes it easy to add the metrics to existing CloudWatch Dashboards.

Metric	Description
DBLoad	The number of active sessions for the DB engine. Typically, you want the data for the average number of active sessions. In Performance Insights, this data is queried as db.load.avg.
DBLoadCPU	The number of active sessions where the wait event type is CPU. In Performance Insights, this data is queried as db.load.avg, filtered by the wait event type CPU.
DBLoadNonCPU	The number of active sessions where the wait event type is not CPU.

Note

These metrics are published to CloudWatch only if there is load on the DB instance.

You can examine these metrics using the CloudWatch console, the AWS CLI, or the CloudWatch API.

For example, you can get the statistics for the DBLoad metric by running the [get-metric-statistics](#) command.

```
aws cloudwatch get-metric-statistics \
--region us-west-2 \
--namespace AWS/RDS \
--metric-name DBLoad \
--period 60 \
--statistics Average \
--start-time 1532035185 \
--end-time 1532036185 \
--dimensions Name=DBInstanceIdentifier,Value=db-loadtest-0
```

This example generates output similar to the following.

```
{
  "Datapoints": [
    {
      "Timestamp": "2021-07-19T21:30:00Z",
      "Unit": "None",
      "Average": 2.1
    },
    {
      "Timestamp": "2021-07-19T21:30:00Z",
      "Unit": "None",
      "Average": 2.1
    }
  ]
}
```

```
"Timestamp": "2021-07-19T21:34:00Z",
"Unit": "None",
"Average": 1.7
},
{
"Timestamp": "2021-07-19T21:35:00Z",
"Unit": "None",
"Average": 2.8
},
{
"Timestamp": "2021-07-19T21:31:00Z",
"Unit": "None",
"Average": 1.5
},
{
"Timestamp": "2021-07-19T21:32:00Z",
"Unit": "None",
"Average": 1.8
},
{
"Timestamp": "2021-07-19T21:29:00Z",
"Unit": "None",
"Average": 3.0
},
{

Performance Insights counter metrics

Counter metrics are operating system and database performance metrics in the Performance Insights dashboard. To help identify and analyze performance problems, you can correlate counter metrics with DB load.

Topics

- [Non-native counters for Amazon RDS for MariaDB and MySQL \(p. 621\)](#)

Native counters for RDS for MariaDB and RDS for MySQL

Native metrics are defined by the database engine and not by Amazon RDS. For definitions of these native metrics, see [Server Status Variables](#) in the MySQL documentation.

Counter	Type	Unit	Metric
Com_analyze	SQL	Queries per second	db.SQL.Com_analyze
Com_optimize	SQL	Queries per second	db.SQL.Com_optimize
Com_select	SQL	Queries per second	db.SQL.Com_select
Connections	SQL	The number of connection attempts per minute (successful or not) to the MySQL server	db.Users.Connections
Innodb_rows_deleted	SQL	Rows per second	db.SQL.Innodb_rows_deleted
Innodb_rows_inserted	SQL	Rows per second	db.SQL.Innodb_rows_inserted
Innodb_rows_read	SQL	Rows per second	db.SQL.Innodb_rows_read
Innodb_rows_updated	SQL	Rows per second	db.SQL.Innodb_rows_updated
Select_full_join	SQL	Queries per second	db.SQL.Select_full_join
Select_full_range_join	SQL	Queries per second	db.SQL.Select_full_range_join
Select_range	SQL	Queries per second	db.SQL.Select_range
Select_range_check	SQL	Queries per second	db.SQL.Select_range_check
Select_scan	SQL	Queries per second	db.SQL.Select_scan
Slow_queries	SQL	Queries per second	db.SQL.Slow_queries
Sort_merge_passes	SQL	Queries per second	db.SQL.Sort_merge_passes
Sort_range	SQL	Queries per second	db.SQL.Sort_range

Counter	Type	Unit	Metric
Sort_rows	SQL	Queries per second	db.SQL.Sort_rows
Sort_scan	SQL	Queries per second	db.SQL.Sort_scan
Questions	SQL	Queries per second	db.SQL.Questions
Innodb_row_lock_time	Locks	Milliseconds (average)	db.Locks.Innodb_row_lock_time
Table_locks_immediate	Locks	Requests per second	db.Locks.Table_locks_immediate
Table_locks_waited	Locks	Requests per second	db.Locks.Table_locks_waited
Aborted_clients	Users	Connections	db.Users.Aborted_clients
Aborted_connects	Users	Connections	db.Users.Aborted_connects
Threads_created	Users	Connections	db.Users.Threads_created
Threads_running	Users	Connections	db.Users.Threads_running
Innodb_data_writes	I/O	Operations per second	db.IO.Innodb_data_writes
Innodb_dblwr_writes	I/O	Operations per second	db.IO.Innodb_dblwr_writes
Innodb_log_write_requests	I/O	Operations per second	db.IO.Innodb_log_write_requests
Innodb_log_writes	I/O	Operations per second	db.IO.Innodb_log_writes
Innodb_pages_written	I/O	Pages per second	db.IO.Innodb_pages_written
Created_tmp_disk_tables	Temp	Tables per second	db.Temp.Created_tmp_disk_tables
Created_tmp_tables	Temp	Tables per second	db.Temp.Created_tmp_tables
Innodb_buffer_pool_pages_data	Cache	Pages	db.Cache.Innodb_buffer_pool_pages_data
Innodb_buffer_pool_pages_total	Cache	Pages	db.Cache.Innodb_buffer_pool_pages_total
Innodb_buffer_pool_read_requests	Cache	Pages per second	db.Cache.Innodb_buffer_pool_read_requests
Innodb_buffer_pool_reads	Cache	Pages per second	db.Cache.Innodb_buffer_pool_reads
Opened_tables	Cache	Tables	db.Cache.Opened_tables

Counter	Type	Unit	Metric
Opened_table_definitions	Cache	Tables	db.Cache.Opened_table_definitions
Qcache_hits	Cache	Queries	db.Cache.Qcache_hits

Non-native counters for Amazon RDS for MariaDB and MySQL

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.

Counter	Type	Metric	Description	Definition
innodb_buffer_pool_hits	Cache	db.Cache.innoDB_buffer_pool_hits	Number of reads that InnoDB could satisfy from the buffer pool.	innodb_buffer_pool_read_requests - innodb_buffer_pool_reads
innodb_buffer_pool_hit_rate	Cache	db.Cache.innoDB_buffer_pool_hit_rate	Percentage of reads that InnoDB could satisfy from the buffer pool.	100 * innodb_buffer_pool_read_requests / (innodb_buffer_pool_read_requests + innodb_buffer_pool_reads)
innodb_buffer_pool_usage	Cache	db.Cache.innoDB_buffer_pool_usage	Percentage of the InnoDB buffer pool that contains data (pages).	Innodb_buffer_pool_pages_data / Innodb_buffer_pool_pages_total * 100.0

Note
When using compressed tables, this value can vary. For more information, see the information about Innodb_buffer_pool_pages_data and Innodb_buffer_pool_pages_total in Server.

Counter	Type	Metric	Description	Definition
			Status Variables in the MySQL documentation.	
query_cache_hit_rate	Cache	db.Cache.query_cache_hit	MySQL result set cache (query cache) hit ratio.	Qcache_hits / (QCache_hits + Com_select) * 100
innodb_datafile_writes_to_d	IO	db.IO.innoDB_datafile_writes	The number of InnoDB data file writes to disk, excluding double write and redo logging write operations.	Innodb_data_writes - Innodb_log_writes - Innodb dblwr_writes
innodb_rows_changed	SQL	db.SQL.innodb_rows_change	The total InnoDB row operations.	db.SQL.Innodb_rows_inserted + db.SQL.Innodb_rows_deleted + db.SQL.Innodb_rows_updated
active_transactions	Transactions	db.Transactions.active_transactions	The total active transactions.	SELECT COUNT(1) AS active_transactions FROM INFORMATION_SCHEMA.INNODB_TRX
trx_rseg_history_len	Transactions	db.Transactions.trx_rseg_history	History of the undo log pages for committed transactions that is maintained by the InnoDB transaction system to implement multi-version concurrency control. For more information about undo log records details, see https://dev.mysql.com/doc/refman/8.0/en/innodb-multi-versioning.html in the MySQL documentation.	SELECT COUNT AS trx_rseg_history_len FROM INFORMATION_SCHEMA.INNODB_METRIC WHERE NAME='trx_rseg_history_len'

Counter	Type	Metric	Description	Definition
innodb_deadlocks	Locks	db.Locks.innodb_deadlocks	The total number of deadlocks.	SELECT COUNT AS innodb_deadlocks FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='lock_deadlocks'
innodb_lock_timeouts	Locks	db.Locks.innodb_lock_timeouts	The total number of locks that timed out.	SELECT COUNT AS innodb_lock_timeouts FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='lock_timeouts'
innodb_row_lock_waits	Locks	db.Locks.innodb_row_lock_waits	The total number of row locks that resulted in a wait.	SELECT COUNT AS innodb_row_lock_waits FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='lock_row_lock_waits'

Performance Insights counters for Amazon RDS for Microsoft SQL Server

The following database counters are available with Performance Insights for RDS for Microsoft SQL Server.

Native counters for RDS for Microsoft SQL Server

Native metrics are defined by the database engine and not by Amazon RDS. You can find definitions for these native metrics in [Use SQL Server Objects](#) in the Microsoft SQL Server documentation.

Counter	Type	Unit	Metric
Forwarded Records	Access Methods	Records per second	db.Access Methods.Forwarded Records
Page Splits	Access Methods	Splits per second	db.Access Methods.Page Splits
Buffer cache hit ratio	Buffer Manager	Ratio	db.Buffer Manager.Buffer cache hit ratio
Page life expectancy	Buffer Manager	Expectancy in seconds	db.Buffer Manager.Page life expectancy
Page lookups	Buffer Manager	Lookups per second	db.Buffer Manager.Page lookups
Page reads	Buffer Manager	Reads per second	db.Buffer Manager.Page reads

Counter	Type	Unit	Metric
Page writes	Buffer Manager	Writes per second	db.Buffer Manager.Page writes
Active Transactions	Databases	Transactions	db.Databases.Active Transactions (_Total)
Log Bytes Flushed	Databases	Bytes flushed per second	db.Databases.Log Bytes Flushed (_Total)
Log Flush Waits	Databases	Waits per second	db.Databases.Log Flush Waits (_Total)
Log Flushes	Databases	Flushes per second	db.Databases.Log Flushes (_Total)
Write Transactions	Databases	Transactions per second	db.Databases.Write Transactions (_Total)
Processes blocked	General Statistics	Processes blocked	db.General Statistics.Processes blocked
User Connections	General Statistics	Connections	db.General Statistics.User Connections
Latch Waits	Latches	Waits per second	db.Latches.Latch Waits
Number of Deadlocks	Locks	Deadlocks per second	db.Locks.Number of Deadlocks (_Total)
Memory Grants Pending	Memory Manager	Memory grants	db.Memory Manager.Memory Grants Pending
Batch Requests	SQL Statistics	Requests per second	db.SQL Statistics.Batch Requests
SQL Compilations	SQL Statistics	Compilations per second	db.SQL Statistics.SQL Compilations
SQL Re-Compilations	SQL Statistics	Re-compilations per second	db.SQL Statistics.SQL Re-Compilations

Performance Insights counters for Amazon RDS for Oracle

The following database counters are available with Performance Insights for RDS for Oracle.

Native counters for RDS for Oracle

Native metrics are defined by the database engine and not by Amazon RDS. You can find definitions for these native metrics in [Statistics Descriptions](#) in the Oracle documentation.

Note

For the CPU used by this session counter metric, the unit has been transformed from the native centiseconds to active sessions to make the value easier to use. For example, CPU send in the DB Load chart represents the demand for CPU. The counter metric CPU used by this

session represents the amount of CPU used by Oracle sessions. You can compare CPU send to the CPU used by this session counter metric. When demand for CPU is higher than CPU used, sessions are waiting for CPU time.

Counter	Type	Unit	Metric
CPU used by this session	User	Active sessions	db.User.CPU used by this session
SQL*Net roundtrips to/from client	User	Roundtrips per second	db.User.SQL*Net roundtrips to/from client
Bytes received via SQL*Net from client	User	Bytes per second	db.User.bytes received via SQL*Net from client
User commits	User	Commits per second	db.User.user commits
Logons cumulative	User	Logons per second	db.User.logons cumulative
User calls	User	Calls per second	db.User.user calls
Bytes sent via SQL*Net to client	User	Bytes per second	db.User.bytes sent via SQL*Net to client
User rollbacks	User	Rollbacks per second	db.User.user rollbacks
Redo size	Redo	Bytes per second	db.Redo.redo size
Parse count (total)	SQL	Parses per second	db.SQL.parse count (total)
Parse count (hard)	SQL	Parses per second	db.SQL.parse count (hard)
Table scan rows gotten	SQL	Rows per second	db.SQL.table scan rows gotten
Sorts (memory)	SQL	Sorts per second	db.SQL.sorts (memory)
Sorts (disk)	SQL	Sorts per second	db.SQL.sorts (disk)
Sorts (rows)	SQL	Sorts per second	db.SQL.sorts (rows)
Physical read bytes	Cache	Bytes per second	db.Cache.physical read bytes
DB block gets	Cache	Blocks per second	db.Cache.db block gets
DBWR checkpoints	Cache	Checkpoints per minute	db.Cache.DBWR checkpoints
Physical reads	Cache	Reads per second	db.Cache.physical reads
Consistent gets from cache	Cache	Gets per second	db.Cache.consistent gets from cache
DB block gets from cache	Cache	Gets per second	db.Cache.db block gets from cache

Counter	Type	Unit	Metric
Consistent gets	Cache	Gets per second	db.Cache.consistent_gets

Performance Insights counters for Amazon RDS for PostgreSQL

The following database counters are available with Performance Insights for Amazon RDS for PostgreSQL.

Topics

- [Native counters for Amazon RDS for PostgreSQL \(p. 626\)](#)
- [Non-native counters for Amazon RDS for PostgreSQL \(p. 627\)](#)

Native counters for Amazon RDS for PostgreSQL

Native metrics are defined by the database engine and not by Amazon RDS. You can find definitions for these native metrics in [Viewing Statistics](#) in the PostgreSQL documentation.

Counter	Type	Unit	Metric
blk_hit	Cache	Blocks per second	db.Cache.blk_hit
buffers_alloc	Cache	Blocks per second	db.Cache.buffers_alloc
buffers_checkpoint	Checkpoint	Blocks per second	db.Checkpoint.buffers_checkpoint
checkpoint_sync_time	Checkpoint	Milliseconds per checkpoint	db.Checkpoint.checkpoint_sync_time
checkpoint_write_time	Checkpoint	Milliseconds per checkpoint	db.Checkpoint.checkpoint_write_time
checkpoints_req	Checkpoint	Checkpoints per minute	db.Checkpoint.checkpoints_req
checkpoints_timed	Checkpoint	Checkpoints per minute	db.Checkpoint.checkpoints_timed
maxwritten_clean	Checkpoint	Bgwriter clean stops per minute	db.Checkpoint.maxwritten_clean
deadlocks	Concurrency	Deadlocks per minute	db.Concurrency.deadlocks
blk_read_time	I/O	Milliseconds	db.IO.blk_read_time
blks_read	I/O	Blocks per second	db.IO.blks_read
buffers_backend	I/O	Blocks per second	db.IO.buffers_backend
buffers_backend_fsync	I/O	Blocks per second	db.IO.buffers_backend_fsync
buffers_clean	I/O	Blocks per second	db.IO.buffers_clean
tup_deleted	SQL	Tuples per second	db.SQL.tup_deleted
tup_fetched	SQL	Tuples per second	db.SQL.tup_fetched

Counter	Type	Unit	Metric
tup_inserted	SQL	Tuples per second	db.SQL.tup_inserted
tup_returned	SQL	Tuples per second	db.SQL.tup_returned
tup_updated	SQL	Tuples per second	db.SQL.tup_updated
temp_bytes	Temp	Bytes per second	db.Temp.temp_bytes
temp_files	Temp	Files per minute	db.Temp.temp_files
active_transactions	Transactions	Transactions	db.Transactions.active_transactions
blocked_transactions	Transactions	Transactions	db.Transactions.blocked_transactions
max_used_xact_ids	Transactions	Transactions	db.Transactions.max_used_xact_ids
xact_commit	Transactions	Commits per second	db.Transactions.xact_commit
xact_rollback	Transactions	Rollbacks per second	db.Transactions.xact_rollback
numbackends	User	Connections	db.User.numbackends
archived_count	Write-ahead log (WAL)	Files per minute	db.WAL.archived_count
archive_failed_count	WAL	Files per minute	db.WAL.archive_failed_count

Non-native counters for Amazon RDS for PostgreSQL

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.

Counter	Type	Metric	Description	Definition
checkpoint_sync_lateness	Checkpoint	db.Checkpoint.checkpoint_sync_lateness	The total amount of time that has been spent in the portion of checkpoint processing where files are synchronized to disk.	checkpoint_sync_time / (checkpoints_timed + checkpoints_req)
checkpoint_write_lateness	Checkpoint	db.Checkpoint.checkpoint_write_lateness	The total amount of time that has been spent in the portion of checkpoint processing where files are written to disk.	checkpoint_write_time / (checkpoints_timed + checkpoints_req)
read_latency	I/O	db.IO.read_latency	The time spent reading data file blocks by backends in this instance.	blk_read_time / blks_read

SQL statistics for Performance Insights

SQL statistics are performance-related metrics about SQL queries that are collected by Performance Insights. Performance Insights gathers statistics for each second that a query is running and for each SQL call.

A SQL digest is a composite of all queries having a given pattern but not necessarily having the same literal values. The digest replaces literal values with a question mark. For example, `SELECT * FROM emp WHERE lname= ?`. This digest might consist of the following child queries:

```
SELECT * FROM emp WHERE lname = 'Sanchez'  
SELECT * FROM emp WHERE lname = 'Olagappan'  
SELECT * FROM emp WHERE lname = 'Wu'
```

All engines support SQL statistics for digest queries.

Topics

- [SQL statistics for MariaDB and MySQL \(p. 628\)](#)
- [SQL statistics for Oracle \(p. 630\)](#)
- [SQL statistics for RDS PostgreSQL \(p. 632\)](#)

SQL statistics for MariaDB and MySQL

MariaDB and MySQL collect SQL statistics only at the digest level. No statistics are shown at the statement level.

Topics

- [Digest statistics for MariaDB and MySQL \(p. 628\)](#)
- [Per-second statistics for MariaDB and MySQL \(p. 629\)](#)
- [Per-call statistics for MariaDB and MySQL \(p. 629\)](#)

Digest statistics for MariaDB and MySQL

Performance Insights collects SQL digest statistics from the `events_statements_summary_by_digest` table. The `events_statements_summary_by_digest` table is managed by your database.

The digest table doesn't have an eviction policy. When the table is full, the AWS Management Console shows the following message:

Performance Insights is unable to collect SQL Digest statistics on new queries because the table `events_statements_summary_by_digest` is full.
Please truncate `events_statements_summary_by_digest` table to clear the issue. Check the User Guide for more details.

In this situation, MariaDB and MySQL don't track SQL queries. To address this issue, Performance Insights automatically truncates the digest table when both of the following conditions are met:

- The table is full.
- Performance Insights manages the Performance Schema automatically.

For automatic management, the `performance_schema` parameter must be set to `0` and the **Source** must not be set to `user`. If Performance Insights isn't managing the Performance Schema automatically, see [Turning on the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL \(p. 553\)](#).

In the AWS CLI, check the source of a parameter value by running the `describe-db-parameters` command.

Per-second statistics for MariaDB and MySQL

The following SQL statistics are available for MariaDB and MySQL DB instances.

Metric	Unit
<code>db.sql_tokenized.stats.count_star_per_sec</code>	Calls per second
<code>db.sql_tokenized.stats.sum_timer_wait_per_sec</code>	Average active executions per second (AAE)
<code>db.sql_tokenized.stats.sum_select_full_join_per_sec</code>	Select full join per second
<code>db.sql_tokenized.stats.sum_select_range_check_per_sec</code>	Select range check per second
<code>db.sql_tokenized.stats.sum_select_scan_per_sec</code>	Select scan per second
<code>db.sql_tokenized.stats.sum_sort_merge_passes_per_sec</code>	Sort merge passes per second
<code>db.sql_tokenized.stats.sum_sort_scan_per_sec</code>	Sort scans per second
<code>db.sql_tokenized.stats.sum_sort_range_per_sec</code>	Sort ranges per second
<code>db.sql_tokenized.stats.sum_sort_rows_per_sec</code>	Sort rows per second
<code>db.sql_tokenized.stats.sum_rows_affected_per_sec</code>	Rows affected per second
<code>db.sql_tokenized.stats.sum_rows_examined_per_sec</code>	Rows examined per second
<code>db.sql_tokenized.stats.sum_rows_sent_per_sec</code>	Rows sent per second
<code>db.sql_tokenized.stats.sum_created_tmp_disk_tables_per_sec</code>	Created temporary disk tables per second
<code>db.sql_tokenized.stats.sum_created_tmp_tables_per_sec</code>	Created temporary tables per second
<code>db.sql_tokenized.stats.sum_lock_time_per_sec</code>	Lock time per second (in ms)

Per-call statistics for MariaDB and MySQL

The following metrics provide per call statistics for a SQL statement.

Metric	Unit
<code>db.sql_tokenized.stats.sum_timer_wait_per_call</code>	Average latency per call (in ms)
<code>db.sql_tokenized.stats.sum_select_full_join_per_call</code>	Select full joins per call
<code>db.sql_tokenized.stats.sum_select_range_check_per_call</code>	Select range check per call
<code>db.sql_tokenized.stats.sum_select_scan_per_call</code>	Select scans per call

Metric	Unit
db.sql_tokenized.stats.sum_sort_merge_passes_per_call	Sort merge passes per call
db.sql_tokenized.stats.sum_sort_scan_per_call	Sort scans per call
db.sql_tokenized.stats.sum_sort_range_per_call	Sort ranges per call
db.sql_tokenized.stats.sum_sort_rows_per_call	Sort rows per call
db.sql_tokenized.stats.sum_rows_affected_per_call	Rows affected per call
db.sql_tokenized.stats.sum_rows_examined_per_call	Rows examined per call
db.sql_tokenized.stats.sum_rows_sent_per_call	Rows sent per call
db.sql_tokenized.stats.sum_created_tmp_disk_tables_per_call	Created temporary disk tables per call
db.sql_tokenized.stats.sum_created_tmp_tables_per_call	Created temporary tables per call
db.sql_tokenized.stats.sum_lock_time_per_call	Lock time per call (in ms)

SQL statistics for Oracle

Amazon RDS for Oracle collects SQL statistics both at the statement and digest level. At the statement level, the ID column represents the value of V\$SQL.SQL_ID. At the digest level, the ID column shows the value of V\$SQL.FORCE_MATCHING_SIGNATURE.

If the ID is 0 at the digest level, Oracle Database has determined that this statement is not suitable for reuse. In this case, the child SQL statements could belong to different digests. However, the statements are grouped together under the digest_text for the first SQL statement collected.

Topics

- [Per-second statistics for Oracle \(p. 630\)](#)
- [Per-call statistics for Oracle \(p. 631\)](#)

Per-second statistics for Oracle

The following metrics provide per-second statistics for an Oracle SQL query.

Metric	Unit
db.sql.stats.executions_per_sec	Number of executions per second
db.sql.stats.elapsed_time_per_sec	Average active executions (AAE)
db.sql.stats.rows_processed_per_sec	Rows processed per second
db.sql.stats.buffer_gets_per_sec	Buffer gets per second
db.sql.stats.physical_read_requests_per_sec	Physical reads per second
db.sql.stats.physical_write_requests_per_sec	Physical writes per second
db.sql.stats.total_sharable_mem_per_sec	Total shareable memory per second (in bytes)
db.sql.stats.cpu_time_per_sec	CPU time per second (in ms)

The following metrics provide per-call statistics for an Oracle SQL digest query.

Metric	Unit
db.sql_tokenized.stats.executions_per_sec	Number of executions per second
db.sql_tokenized.stats.elapsed_time_per_sec	Average active executions (AAE)
db.sql_tokenized.stats.rows_processed_per_sec	Rows processed per second
db.sql_tokenized.stats.buffer_gets_per_sec	Buffer gets per second
db.sql_tokenized.stats.physical_read_requests_per_sec	Physical reads per second
db.sql_tokenized.stats.physical_write_requests_per_sec	Physical writes per second
db.sql_tokenized.stats.total_sharable_mem_per_sec	Total shareable memory per second (in bytes)
db.sql_tokenized.stats.cpu_time_per_sec	CPU time per second (in ms)

Per-call statistics for Oracle

The following metrics provide per-call statistics for an Oracle SQL statement.

Metric	Unit
db.sql.stats.elapsed_time_per_exec	Elapsed time per executions (in ms)
db.sql.stats.rows_processed_per_exec	Rows processed per execution
db.sql.stats.buffer_gets_per_exec	Buffer gets per execution
db.sql.stats.physical_read_requests_per_exec	Physical reads per execution
db.sql.stats.physical_write_requests_per_exec	Physical writes per execution
db.sql.stats.total_sharable_mem_per_exec	Total shareable memory per execution (in bytes)
db.sql.stats.cpu_time_per_exec	CPU time per execution (in ms)

The following metrics provide per-call statistics for an Oracle SQL digest query.

Metric	Unit
db.sql_tokenized.stats.elapsed_time_per_exec	Elapsed time per executions (in ms)
db.sql_tokenized.stats.rows_processed_per_exec	Rows processed per execution
db.sql_tokenized.stats.buffer_gets_per_exec	Buffer gets per execution
db.sql_tokenized.stats.physical_read_requests_per_exec	Physical reads per execution
db.sql_tokenized.stats.physical_write_requests_per_exec	Physical writes per execution
db.sql_tokenized.stats.total_sharable_mem_per_exec	Total shareable memory per execution (in bytes)
db.sql_tokenized.stats.cpu_time_per_exec	CPU time per execution (in ms)

SQL statistics for RDS PostgreSQL

For each SQL call and for each second that a query runs, Performance Insights collects SQL statistics. RDS for PostgreSQL collect SQL statistics only at the digest-level. No statistics are shown at the statement-level.

Following, you can find information about digest-level statistics for RDS for PostgreSQL.

Topics

- [Digest statistics for RDS PostgreSQL \(p. 632\)](#)
- [Per-second digest statistics for RDS PostgreSQL \(p. 632\)](#)
- [Per-call digest statistics for RDS PostgreSQL \(p. 633\)](#)

Digest statistics for RDS PostgreSQL

To view SQL digest statistics, RDS PostgreSQL must load the pg_stat_statements library. For PostgreSQL DB instances that are compatible with PostgreSQL 11 or later, the database loads this library by default. For PostgreSQL DB instances that are compatible with PostgreSQL 10 or earlier, enable this library manually. To enable it manually, add pg_stat_statements to shared_preload_libraries in the DB parameter group associated with the DB instance. Then reboot your DB instance. For more information, see [Working with parameter groups \(p. 289\)](#).

Note

Performance Insights can only collect statistics for queries in pg_stat_activity that aren't truncated. By default, PostgreSQL databases truncate queries longer than 1,024 bytes. To increase the query size, change the track_activity_query_size parameter in the DB parameter group associated with your DB instance. When you change this parameter, a DB instance reboot is required.

Per-second digest statistics for RDS PostgreSQL

The following SQL digest statistics are available for PostgreSQL DB instances.

Metric	Unit
db.sql_tokenized.stats.calls_per_sec	Calls per second
db.sql_tokenized.stats.rows_per_sec	Rows per second
db.sql_tokenized.stats.total_time_per_sec	Average active executions per second (AAE)
db.sql_tokenized.stats.shared_blk_hit_per_sec	Block hits per second
db.sql_tokenized.stats.shared_blk_read_per_sec	Block reads per second
db.sql_tokenized.stats.shared_blk_dirtied_per_sec	Blocks dirtied per second
db.sql_tokenized.stats.shared_blk_written_per_sec	Block writes per second
db.sql_tokenized.stats.local_blk_hit_per_sec	Local block hits per second
db.sql_tokenized.stats.local_blk_read_per_sec	Local block reads per second
db.sql_tokenized.stats.local_blk_dirtied_per_sec	Local block dirty per second
db.sql_tokenized.stats.local_blk_written_per_sec	Local block writes per second

Metric	Unit
db.sql_tokenized.stats.temp_blk_written_per_sec	Temporary writes per second
db.sql_tokenized.stats.temp_blk_read_per_sec	Temporary reads per second
db.sql_tokenized.stats.blk_read_time_per_sec	Average concurrent reads per second
db.sql_tokenized.stats.blk_write_time_per_sec	Average concurrent writes per second

Per-call digest statistics for RDS PostgreSQL

The following metrics provide per call statistics for a SQL statement.

Metric	Unit
db.sql_tokenized.stats.rows_per_call	Rows per call
db.sql_tokenized.stats.avg_latency_per_call	Average latency per call (in ms)
db.sql_tokenized.stats.shared_blk_hit_per_call	Block hits per call
db.sql_tokenized.stats.shared_blk_read_per_call	Block reads per call
db.sql_tokenized.stats.shared_blk_written_per_call	Block writes per call
db.sql_tokenized.stats.shared_blk_dirtied_per_call	Blocks dirtied per call
db.sql_tokenized.stats.local_blk_hit_per_call	Local block hits per call
db.sql_tokenized.stats.local_blk_read_per_call	Local block reads per call
db.sql_tokenized.stats.local_blk_dirtied_per_call	Local block dirty per call
db.sql_tokenized.stats.local_blk_written_per_call	Local block writes per call
db.sql_tokenized.stats.temp_blk_written_per_call	Temporary block writes per call
db.sql_tokenized.stats.temp_blk_read_per_call	Temporary block reads per call
db.sql_tokenized.stats.blk_read_time_per_call	Read time per call (in ms)
db.sql_tokenized.stats.blk_write_time_per_call	Write time per call (in ms)

For more information about these metrics, see [pg_stat_statements](#) in the PostgreSQL documentation.

OS metrics in Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. RDS delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. The following tables list the OS metrics available using Amazon CloudWatch Logs.

Topics

- [OS metrics for MariaDB, MySQL, Oracle, and PostgreSQL \(p. 634\)](#)
- [OS metrics for Microsoft SQL Server \(p. 639\)](#)

OS metrics for MariaDB, MySQL, Oracle, and PostgreSQL

Group	Metric	Console name	Description
General	engine	Not applicable	The database engine for the DB instance.
	instanceID	Not applicable	The DB instance identifier.
	instanceResouceID	Not applicable	An immutable identifier for the DB instance that is unique to an AWS Region, also used as the log stream identifier.
	numVCpus	Not applicable	The number of virtual CPUs for the DB instance.
	timestamp	Not applicable	The time at which the metrics were taken.
	uptime	Not applicable	The amount of time that the DB instance has been active.
	version	Not applicable	The version of the OS metrics' stream JSON format.
cpuUtilization	guest	CPU Guest	The percentage of CPU in use by guest programs.
	idle	CPU Idle	The percentage of CPU that is idle.
	irq	CPU IRQ	The percentage of CPU in use by software interrupts.
	nice	CPU Nice	The percentage of CPU in use by programs running at lowest priority.
	steal	CPU Steal	The percentage of CPU in use by other virtual machines.
	system	CPU System	The percentage of CPU in use by the kernel.
	total	CPU Total	The total percentage of the CPU in use. This value includes the nice value.
	user	CPU User	The percentage of CPU in use by user programs.
	wait	CPU Wait	The percentage of CPU unused while waiting for I/O access.
diskIO	avgQueueLen	Avg Queue Size	The number of requests waiting in the I/O device's queue.
	avgReqSz	Ave Request Size	The average request size, in kilobytes.
	await	Disk I/O Await	The number of milliseconds required to respond to requests, including queue time and service time.
	device	Not applicable	The identifier of the disk device in use.
	readIosPS	Read IO/s	The number of read operations per second.

Group	Metric	Console name	Description
read/write metrics	readKb	Read Total	The total number of kilobytes read.
	readKbPS	Read Kb/s	The number of kilobytes read per second.
	readLatency	Read Latency	The elapsed time between the submission of a read I/O request and its completion, in milliseconds. This metric is only available for Amazon Aurora.
	readThroughput	Read Throughput	The amount of network throughput used by requests to the DB cluster, in bytes per second. This metric is only available for Amazon Aurora.
	rrqmPS	Rrqms	The number of merged read requests queued per second.
	tps	TPS	The number of I/O transactions per second.
	util	Disk I/O Util	The percentage of CPU time during which requests were issued.
	writeI0sPS	Write IO/s	The number of write operations per second.
	writeKb	Write Total	The total number of kilobytes written.
	writeKbPS	Write Kb/s	The number of kilobytes written per second.
	writeLatency	Write Latency	The average elapsed time between the submission of a write I/O request and its completion, in milliseconds. This metric is only available for Amazon Aurora.
	writeThroughput	Write Throughput	The amount of network throughput used by responses from the DB cluster, in bytes per second. This metric is only available for Amazon Aurora.
	wrqmPS	Wrqms	The number of merged write requests queued per second.
physicalDevice metrics	ioQueueLen	Physical Devices Avg Queue Size	The number of requests waiting in the I/O device's queue.
	avgReqSz	Physical Devices Ave Request Size	The average request size, in kilobytes.
	await	Physical Devices Disk I/O Await	The number of milliseconds required to respond to requests, including queue time and service time.
	device	Not applicable	The identifier of the disk device in use.
	readI0sPS	Physical Devices Read IO/s	The number of read operations per second.

Group	Metric	Console name	Description
	readKb	Physical Devices Read Total	The total number of kilobytes read.
	readKbPS	Physical Devices Read Kb/s	The number of kilobytes read per second.
	rrqmPS	Physical Devices Rrqms	The number of merged read requests queued per second.
	tps	Physical Devices TPS	The number of I/O transactions per second.
	util	Physical Devices Disk I/O Util	The percentage of CPU time during which requests were issued.
	writeI0sPS	Physical Devices Write IO/s	The number of write operations per second.
	writeKb	Physical Devices Write Total	The total number of kilobytes written.
	writeKbPS	Physical Devices Write Kb/s	The number of kilobytes written per second.
	wrqmPS	Physical Devices Wrqms	The number of merged write requests queued per second.
fileSys	maxFiles	Max Inodes	The maximum number of files that can be created for the file system.
	mountPoint	Not applicable	The path to the file system.
	name	Not applicable	The name of the file system.
	total	Total Filesystem	The total number of disk space available for the file system, in kilobytes.
	used	Used Filesystem	The amount of disk space used by files in the file system, in kilobytes.
	usedFilePercent	Used %	The percentage of available files in use.
	usedFiles	Used Inodes	The number of files in the file system.
	usedPercent	Used Inodes %	The percentage of the file-system disk space in use.

Group	Metric	Console name	Description
loadAverage	fifteen	Load Avg 15 min	The number of processes requesting CPU time over the last 15 minutes.
	five	Load Avg 5 min	The number of processes requesting CPU time over the last 5 minutes.
	one	Load Avg 1 min	The number of processes requesting CPU time over the last minute.
memory	active	Active Memory	The amount of assigned memory, in kilobytes.
	buffers	Buffered Memory	The amount of memory used for buffering I/O requests prior to writing to the storage device, in kilobytes.
	cached	Cached Memory	The amount of memory used for caching file system-based I/O.
	dirty	Dirty Memory	The amount of memory pages in RAM that have been modified but not written to their related data block in storage, in kilobytes.
	free	Free Memory	The amount of unassigned memory, in kilobytes.
	hugePagesFree	Huge Pages Free	The number of free huge pages. Huge pages are a feature of the Linux kernel.
	hugePagesRsvd	Huge Pages Rsvd	The number of committed huge pages.
	hugePagesSz	Huge Pages Size	The size for each huge pages unit, in kilobytes.
	hugePagesSurp	Huge Pages Surp	The number of available surplus huge pages over the total.
	hugePagesTotal	Huge Pages Total	The total number of huge pages.
	inactive	Inactive Memory	The amount of least-frequently used memory pages, in kilobytes.
	mapped	Mapped Memory	The total amount of file-system contents that is memory mapped inside a process address space, in kilobytes.
	pageTables	Page Tables	The amount of memory used by page tables, in kilobytes.
	slab	Slab Memory	The amount of reusable kernel data structures, in kilobytes.
	total	Total Memory	The total amount of memory, in kilobytes.
	writeback	Writeback Memory	The amount of dirty pages in RAM that are still being written to the backing storage, in kilobytes.

Group	Metric	Console name	Description
network	interface	Not applicable	The identifier for the network interface being used for the DB instance.
	rx	RX	The number of bytes received per second.
	tx	TX	The number of bytes uploaded per second.
processList	cpuUsedPc	CPU %	The percentage of CPU used by the process.
	id	Not applicable	The identifier of the process.
	memoryUsedPc	MEM%	The percentage of memory used by the process.
	name	Not applicable	The name of the process.
	parentID	Not applicable	The process identifier for the parent process of the process.
	rss	RES	The amount of RAM allocated to the process, in kilobytes.
	tgid	Not applicable	The thread group identifier, which is a number representing the process ID to which a thread belongs. This identifier is used to group threads from the same process.
	vss	VIRT	The amount of virtual memory allocated to the process, in kilobytes.
swap	swap	Swap	The amount of swap memory available, in kilobytes.
	swap_in	Swaps in	The amount of memory, in kilobytes, swapped in from disk.
	swap_out	Swaps out	The amount of memory, in kilobytes, swapped out to disk.
	free	Free Swap	The amount of swap memory free, in kilobytes.
	committed	Committed Swap	The amount of swap memory, in kilobytes, used as cache memory.
tasks	blocked	Tasks Blocked	The number of tasks that are blocked.
	running	Tasks Running	The number of tasks that are running.
	sleeping	Tasks Sleeping	The number of tasks that are sleeping.
	stopped	Tasks Stopped	The number of tasks that are stopped.
	total	Tasks Total	The total number of tasks.

Group	Metric	Console name	Description
	zombie	Tasks Zombie	The number of child tasks that are inactive with an active parent task.

OS metrics for Microsoft SQL Server

Group	Metric	Console name	Description
General	engine	Not applicable	The database engine for the DB instance.
	instanceID	Not applicable	The DB instance identifier.
	instanceResourceIdentifier	Not applicable	An immutable identifier for the DB instance that is unique to an AWS Region, also used as the log stream identifier.
	numVCpus	Not applicable	The number of virtual CPUs for the DB instance.
	timestamp	Not applicable	The time at which the metrics were taken.
	uptime	Not applicable	The amount of time that the DB instance has been active.
	version	Not applicable	The version of the OS metrics' stream JSON format.
cpuUtilization	idle	CPU Idle	The percentage of CPU that is idle.
	kern	CPU Kernel	The percentage of CPU in use by the kernel.
	user	CPU User	The percentage of CPU in use by user programs.
disks	name	Not applicable	The identifier for the disk.
	totalKb	Total Disk Space	The total space of the disk, in kilobytes.
	usedKb	Used Disk Space	The amount of space used on the disk, in kilobytes.
	usedPc	Used Disk Space %	The percentage of space used on the disk.
	availKb	Available Disk Space	The space available on the disk, in kilobytes.
	availPc	Available Disk Space %	The percentage of space available on the disk.
	rdCountPS	Reads/s	The number of read operations per second
	rdBytesPS	Read Kb/s	The number of bytes read per second.
	wrCountPS	Write IO/s	The number of write operations per second.
	wrBytesPS	Write Kb/s	The amount of bytes written per second.

Group	Metric	Console name	Description
memory	commitTotKb	Commit Total	The amount of pagefile-backed virtual address space in use, that is, the current commit charge. This value is composed of main memory (RAM) and disk (pagefiles).
	commitLimitKb	Maximum Commit	The maximum possible value for the commitTotKb metric. This value is the sum of the current pagefile size plus the physical memory available for pageable contents, excluding RAM that is assigned to nonpageable areas.
	commitPeakKb	Commit Peak	The largest value of the commitTotKb metric since the operating system was last started.
	kernTotKb	Total Kernel Memory	The sum of the memory in the paged and nonpaged kernel pools, in kilobytes.
	kernPagedKb	Paged Kernel Memory	The amount of memory in the paged kernel pool, in kilobytes.
	kernNonpagedKb	Nonpaged Kerenel Memory	The amount of memory in the nonpaged kernel pool, in kilobytes.
	pageSize	Page Size	The size of a page, in bytes.
	physTotKb	Total Memory	The amount of physical memory, in kilobytes.
	physAvailKb	Available Memory	The amount of available physical memory, in kilobytes.
	sqlServerTotKb	SQL Server Total Memory	The amount of memory committed to SQL Server, in kilobytes.
network	sysCacheKb	System Cache	The amount of system cache memory, in kilobytes.
	interface	Not applicable	The identifier for the network interface being used for the DB instance.
	rdBytesPS	Network Read Kb/s	The number of bytes received per second.
processList	wrBytesPS	Network Write Kb/s	The number of bytes sent per second.
	cpuUsedPc	Used %	The percentage of CPU used by the process.
	memUsedPc	MEM%	The percentage of total memory used by the process.
	name	Not applicable	The name of the process.
	pid	Not applicable	The identifier of the process. This value is not present for processes that are owned by Amazon RDS.

Group	Metric	Console name	Description
	ppid	Not applicable	The process identifier for the parent of this process. This value is only present for child processes.
	tid	Not applicable	The thread identifier. This value is only present for threads. The owning process can be identified by using the pid value.
	workingSetKb	Not applicable	The amount of memory in the private working set plus the amount of memory that is in use by the process and can be shared with other processes, in kilobytes.
	workingSetPrivKb	Not applicable	The amount of memory that is in use by a process, but can't be shared with other processes, in kilobytes.
	workingSetSharedKb	Not applicable	The amount of memory that is in use by a process and can be shared with other processes, in kilobytes.
	virtKb	Not applicable	The amount of virtual address space the process is using, in kilobytes. Use of virtual address space doesn't necessarily imply corresponding use of either disk or main memory pages.
system	handles	Handles	The number of handles that the system is using.
	processes	Processes	The number of processes running on the system.
	threads	Threads	The number of threads running on the system.

Monitoring events, logs, and streams in an Amazon RDS DB instance

When you monitor your Amazon RDS databases and your other AWS solutions, your goal is to maintain the following:

- Reliability
- Availability
- Performance
- Security

[Monitoring metrics in an Amazon RDS instance \(p. 510\)](#) explains how to monitor your instance using metrics. A complete solution must also monitor database events, log files, and activity streams. AWS provides you with the following monitoring tools:

- *Amazon EventBridge* is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications, Software-as-a-Service (SaaS) applications, and AWS services. EventBridge routes that data to targets such as AWS Lambda. This way, you can monitor events that happen in services and build event-driven architectures. For more information, see the [Amazon EventBridge User Guide](#).
- *Amazon CloudWatch Logs* provides a way to monitor, store, and access your log files from Amazon RDS instances, AWS CloudTrail, and other sources. Amazon CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the [Amazon CloudWatch Logs User Guide](#).
- *AWS CloudTrail* captures API calls and related events made by or on behalf of your AWS account. CloudTrail delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the [AWS CloudTrail User Guide](#).
- *Database Activity Streams* is an Amazon RDS feature that provides a near real-time stream of the activity in your Oracle DB instance. Amazon RDS pushes activities to an Amazon Kinesis data stream. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Kinesis Data Firehose and AWS Lambda to consume the stream and store the data.

Topics

- [Viewing logs, events, and streams in the Amazon RDS console \(p. 642\)](#)
- [Monitoring Amazon RDS events \(p. 646\)](#)
- [Monitoring Amazon RDS log files \(p. 680\)](#)
- [Monitoring Amazon RDS API calls in AWS CloudTrail \(p. 725\)](#)
- [Monitoring Amazon RDS for Oracle with Database Activity Streams \(p. 729\)](#)

Viewing logs, events, and streams in the Amazon RDS console

Amazon RDS integrates with AWS services to show information about logs, events, and database activity streams in the RDS console.

The **Logs & events** tab for your RDS DB instance shows the following information:

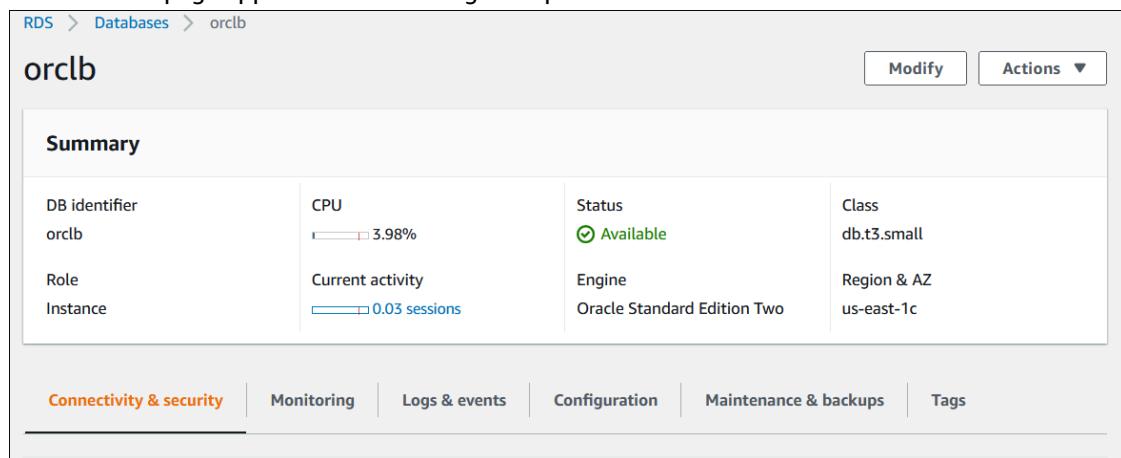

- **Amazon CloudWatch alarms** – Shows any metric alarms that you have configured for the DB instance. If you haven't configured alarms, you can create them in the RDS console. For more information, see [Monitoring Amazon RDS metrics with Amazon CloudWatch \(p. 528\)](#).
- **Recent events** – Shows a summary of events (environment changes) for your RDS DB instance . For more information, see [Viewing Amazon RDS events \(p. 647\)](#).
- **Logs** – Shows database log files generated by a DB instance. For more information, see [Monitoring Amazon RDS log files \(p. 680\)](#).

The **Configuration** tab displays information about database activity streams.

To view logs, events, and streams for your DB instance in the RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that you want to monitor.

The database page appears. The following example shows an Oracle database named orclb.

4. Choose **Logs & events**.

The Logs & events section appears.

The screenshot shows the 'Logs & events' section of the Amazon RDS console. It includes three main sections: 'CloudWatch alarms (0)', 'Recent events (2)', and 'Logs (1478)'. Each section has a search bar, a table header, and a list of items with details.

CloudWatch alarms (0)

Name	State	More options
Empty alarms table		
Create alarm		

Recent events (2)

Time	System notes
February 04, 2022, 10:01:40 AM UTC	Backing up DB instance
February 04, 2022, 10:05:26 AM UTC	Finished DB Instance backup

Logs (1478)

Name	Last written	Logs
audit/ORCLB_j001_23080_20220202220030509284475170.aud	Wed Feb 02 2022 17:01:09 GMT-0500	649.6 kB
audit/ORCLB_j003_450_2022020322001748233361498.aud	Thu Feb 03 2022 17:00:32 GMT-0500	537.7 kB

5. Choose Configuration.

The following example shows the status of the database activity streams for your RDS for Oracle DB instance.

Configuration	Maintenance & backups	Tags
Storage	Performance Insights	
Encryption	Performance Insights enabled	
Not enabled	Yes	
Storage type	AWS KMS key	
General Purpose SSD (gp2)	aws/rds	
Provisioned IOPS	Retention period	
-	731 days	
Storage	Published logs	
98 GiB	CloudWatch Logs	
Storage autoscaling	Alert	
Enabled	Audit	
Maximum storage threshold	Listener	
1000 GiB	Trace	
	Database activity stream	
	Status	
	 Stopped	

Monitoring Amazon RDS events

An *event* indicates a change in an environment. This can be an AWS environment, an SaaS partner service or application, or a custom application or service. For descriptions of the RDS events, see [Amazon RDS event categories and event messages \(p. 668\)](#).

Topics

- [Overview of events for Amazon RDS \(p. 646\)](#)
- [Viewing Amazon RDS events \(p. 647\)](#)
- [Working with Amazon RDS event notification \(p. 650\)](#)
- [Creating a rule that triggers on an Amazon RDS event \(p. 664\)](#)
- [Amazon RDS event categories and event messages \(p. 668\)](#)

Overview of events for Amazon RDS

An *RDS event* indicates a change in the Amazon RDS environment. For example, Amazon RDS generates an event when the state of a DB instance changes from pending to running. Amazon RDS delivers events to CloudWatch Events and EventBridge in near-real time.

Note

Amazon RDS emits events on a best effort basis. We recommend that you avoid writing programs that depend on the order or existence of notification events, because they might be out of sequence or missing.

Amazon RDS records events that relate to the following resources:

- DB instances
 - For a list of DB instance events, see [DB instance events \(p. 669\)](#).
- DB parameter groups
 - For a list of DB parameter group events, see [DB parameter group events \(p. 676\)](#).
- DB security groups
 - For a list of DB security group events, see [DB security group events \(p. 676\)](#).
- DB snapshots
 - For a list of DB snapshot events, see [DB snapshot events \(p. 677\)](#).
- RDS Proxy events
 - For a list of RDS Proxy events, see [RDS Proxy events \(p. 678\)](#).

This information includes the following:

- The date and time of the event
- The source name and source type of the event
- A message associated with the event

Viewing Amazon RDS events

You can retrieve the following event information for your Amazon RDS resources:

- Resource name
- Resource type
- Time of the event
- Message summary of the event

Access the events through the AWS Management Console, which shows events from the past 24 hours. You can also retrieve events by using the [describe-events](#) AWS CLI command, or the [DescribeEvents](#) RDS API operation. If you use the AWS CLI or the RDS API to view events, you can retrieve events for up to the past 14 days.

Note

If you need to store events for longer periods of time, you can send Amazon RDS events to CloudWatch Events. For more information, see [Creating a rule that triggers on an Amazon RDS event \(p. 664\)](#)

For descriptions of the Amazon RDS events, see [Amazon RDS event categories and event messages \(p. 668\)](#).

To access detailed information about events using AWS CloudTrail, including request parameters, see [CloudTrail events \(p. 725\)](#).

Console

To view all Amazon RDS events for the past 24 hours

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Events**.

The available events appear in a list.

3. (Optional) Enter a search term to filter your results.

The following example shows a list of events filtered by the characters **stopped**.

Source	Type	Time	Message
orclb	Instances	March 19, 2021, 7:34:09 PM UTC	DB instance stopped

AWS CLI

To view all events generated in the last hour, call [describe-events](#) with no parameters.

```
aws rds describe-events
```

The following sample output shows that a DB instance has been stopped.

```
{  
    "Events": [  
        {  
            "EventCategories": [  
                "notification"  
            ],  
            "SourceType": "db-instance",  
            "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:testinst",  
            "Date": "2022-04-22T21:31:00.681Z",  
            "Message": "DB instance stopped",  
            "SourceIdentifier": "testinst"  
        }  
    ]  
}
```

To view all Amazon RDS events for the past 10080 minutes (7 days), call the [describe-events](#) AWS CLI command and set the --duration parameter to 10080.

```
aws rds describe-events --duration 10080
```

The following example shows the events in the specified time range for DB instance *test-instance*.

```
aws rds describe-events \  
    --source-identifier test-instance \  
    --source-type db-instance \  
    --start-time 2022-03-13T22:00Z \  
    --end-time 2022-03-13T23:59Z
```

The following sample output shows the status of a backup.

```
{  
    "Events": [  
        {  
            "SourceType": "db-instance",  
            "SourceIdentifier": "test-instance",  
            "EventCategories": [  
                "backup"  
            ],  
            "Message": "Backing up DB instance",  
            "Date": "2022-03-13T23:09:23.983Z",  
            "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:test-instance"  
        },  
        {  
            "SourceType": "db-instance",  
            "SourceIdentifier": "test-instance",  
            "EventCategories": [  
                "backup"  
            ],  
            "Message": "Finished DB Instance backup",  
            "Date": "2022-03-13T23:15:13.049Z",  
            "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:test-instance"  
        }  
    ]  
}
```

API

You can view all Amazon RDS instance events for the past 14 days by calling the [DescribeEvents](#) RDS API operation and setting the `Duration` parameter to 20160.

Working with Amazon RDS event notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint.

Topics

- [Overview of Amazon RDS event notification \(p. 650\)](#)
- [Granting permissions to publish notifications to an Amazon SNS topic \(p. 654\)](#)
- [Subscribing to Amazon RDS event notification \(p. 655\)](#)
- [Listing Amazon RDS event notification subscriptions \(p. 658\)](#)
- [Modifying an Amazon RDS event notification subscription \(p. 659\)](#)
- [Adding a source identifier to an Amazon RDS event notification subscription \(p. 660\)](#)
- [Removing a source identifier from an Amazon RDS event notification subscription \(p. 661\)](#)
- [Listing the Amazon RDS event notification categories \(p. 662\)](#)
- [Deleting an Amazon RDS event notification subscription \(p. 663\)](#)

Overview of Amazon RDS event notification

Amazon RDS groups events into categories that you can subscribe to so that you can be notified when an event in that category occurs.

Topics

- [RDS resources eligible for event subscription \(p. 650\)](#)
- [Basic process for subscribing to Amazon RDS event notifications \(p. 651\)](#)
- [Delivery of RDS event notifications \(p. 651\)](#)
- [Billing for Amazon RDS event notifications \(p. 651\)](#)
- [Examples of Amazon RDS events \(p. 651\)](#)

RDS resources eligible for event subscription

You can subscribe to an event category for the following resources:

- DB instance
- DB snapshot
- DB parameter group
- DB security group
- RDS Proxy
- Custom engine version

For example, if you subscribe to the backup category for a given DB instance, you're notified whenever a backup-related event occurs that affects the DB instance. If you subscribe to a configuration change category for a DB instance, you're notified when the DB instance is changed. You also receive notification when an event notification subscription changes.

You might want to create several different subscriptions. For example, you might create one subscription that receives all event notifications for all DB instances and another subscription that includes only critical events for a subset of the DB instances. For the second subscription, specify one or more DB instances in the filter.

Basic process for subscribing to Amazon RDS event notifications

The process for subscribing to Amazon RDS event notification is as follows:

1. You create an Amazon RDS event notification subscription by using the Amazon RDS console, AWS CLI, or API.

Amazon RDS uses the ARN of an Amazon SNS topic to identify each subscription. The Amazon RDS console creates the ARN for you when you create the subscription. Create the ARN by using the Amazon SNS console, the AWS CLI, or the Amazon SNS API.
2. Amazon RDS sends an approval email or SMS message to the addresses you submitted with your subscription.
3. You confirm your subscription by choosing the link in the notification you received.
4. The Amazon RDS console updates the **My Event Subscriptions** section with the status of your subscription.
5. Amazon RDS begins sending the notifications to the addresses that you provided when you created the subscription.

To learn about identity and access management when using Amazon SNS, see [Identity and access management in Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide*.

You can use AWS Lambda to process event notifications from a DB instance. For more information, see [Using AWS Lambda with Amazon RDS](#) in the *AWS Lambda Developer Guide*.

Delivery of RDS event notifications

Amazon RDS sends notifications to the addresses that you provide when you create the subscription. The notification can include message attributes which provide structured metadata about the message. For more information about message attributes, see [Amazon RDS event categories and event messages \(p. 668\)](#).

Event notifications might take up to five minutes to be delivered.

Important

Amazon RDS doesn't guarantee the order of events sent in an event stream. The event order is subject to change.

When Amazon SNS sends a notification to a subscribed HTTP or HTTPS endpoint, the POST message sent to the endpoint has a message body that contains a JSON document. For more information, see [Amazon SNS message and JSON formats](#) in the *Amazon Simple Notification Service Developer Guide*.

You can configure SNS to notify you with text messages. For more information, see [Mobile text messaging \(SMS\)](#) in the *Amazon Simple Notification Service Developer Guide*.

To turn off notifications without deleting a subscription, choose **No** for **Enabled** in the Amazon RDS console. Or you can set the Enabled parameter to false using the AWS CLI or Amazon RDS API.

Billing for Amazon RDS event notifications

Billing for Amazon RDS event notification is through Amazon SNS. Amazon SNS fees apply when using event notification. For more information about Amazon SNS billing, see [Amazon Simple Notification Service pricing](#).

Examples of Amazon RDS events

The following examples illustrate different types of Amazon RDS events in JSON format. For a tutorial that shows you how to capture and view events in JSON format, see [Tutorial: Log DB instance state changes using Amazon EventBridge \(p. 665\)](#).

Topics

- [Example of a DB instance event \(p. 652\)](#)
- [Example of a DB parameter group event \(p. 652\)](#)
- [Example of a DB snapshot event \(p. 653\)](#)

Example of a DB instance event

The following is an example of a DB instance event in JSON format. The event shows that RDS performed a multi-AZ failover for the instance named my-db-instance. The event ID is RDS-EVENT-0049.

```
{  
    "version": "0",  
    "id": "68f6e973-1a0c-d37b-f2f2-94a7f62ffd4e",  
    "detail-type": "RDS DB Instance Event",  
    "source": "aws.rds",  
    "account": "123456789012",  
    "time": "2018-09-27T22:36:43Z",  
    "region": "us-east-1",  
    "resources": [  
        "arn:aws:rds:us-east-1:123456789012:db:my-db-instance"  
    ],  
    "detail": {  
        "EventCategories": [  
            "failover"  
        ],  
        "SourceType": "DB_INSTANCE",  
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:my-db-instance",  
        "Date": "2018-09-27T22:36:43.292Z",  
        "Message": "A Multi-AZ failover has completed.",  
        "SourceIdentifier": "rds:my-db-instance",  
        "EventID": "RDS-EVENT-0049"  
    }  
}
```

Example of a DB parameter group event

The following is an example of a DB parameter group event in JSON format. The event shows that the parameter time_zone was updated in parameter group my-db-param-group. The event ID is RDS-EVENT-0037.

```
{  
    "version": "0",  
    "id": "844e2571-85d4-695f-b930-0153b71dc42",  
    "detail-type": "RDS DB Parameter Group Event",  
    "source": "aws.rds",  
    "account": "123456789012",  
    "time": "2018-10-06T12:26:13Z",  
    "region": "us-east-1",  
    "resources": [  
        "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group"  
    ],  
    "detail": {  
        "EventCategories": [  
            "configuration change"  
        ],  
        "SourceType": "DB_PARAM",  
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group",  
        "Date": "2018-10-06T12:26:13.882Z",  
        "Message": "Updated parameter time_zone to UTC with apply method immediate",  
    }  
}
```

```
        "SourceIdentifier": "rds:my-db-param-group",
        "EventID": "RDS-EVENT-0037"
    }
```

Example of a DB snapshot event

The following is an example of a DB snapshot event in JSON format. The event shows the deletion of the snapshot named my-db-snapshot. The event ID is RDS-EVENT-0041.

```
{
    "version": "0",
    "id": "844e2571-85d4-695f-b930-0153b71dcb42",
    "detail-type": "RDS DB Snapshot Event",
    "source": "aws.rds",
    "account": "123456789012",
    "time": "2018-10-06T12:26:13Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:123456789012:snapshot:rds:my-db-snapshot"
    ],
    "detail": {
        "EventCategories": [
            "deletion"
        ],
        "SourceType": "SNAPSHOT",
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:snapshot:rds:my-db-snapshot",
        "Date": "2018-10-06T12:26:13.882Z",
        "Message": "Deleted manual snapshot",
        "SourceIdentifier": "rds:my-db-snapshot",
        "EventID": "RDS-EVENT-0041"
    }
}
```

Granting permissions to publish notifications to an Amazon SNS topic

To grant Amazon RDS permissions to publish notifications to an Amazon Simple Notification Service (Amazon SNS) topic, attach an AWS Identity and Access Management (IAM) policy to the destination topic. For more information about permissions, see [Example cases for Amazon Simple Notification Service access control](#) in the *Amazon Simple Notification Service Developer Guide*.

By default, an Amazon SNS topic has a policy allowing all Amazon RDS resources within the same account to publish notifications to it. You can attach a custom policy to allow cross-account notifications, or to restrict access to certain resources.

The following is an example of an IAM policy that you attach to the destination Amazon SNS topic. It restricts the topic to DB instances with names that match the specified prefix. To use this policy, specify the following values:

- Resource – The Amazon Resource Name (ARN) for your Amazon SNS topic
- SourceARN – Your RDS resource ARN
- SourceAccount – Your AWS account ID

To see a list of resource types and their ARNs, see [Resources Defined by Amazon RDS](#) in the *Service Authorization Reference*.

```
{  
    "Version": "2008-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "events.rds.amazonaws.com"  
            },  
            "Action": [  
                "sns:Publish"  
            ],  
            "Resource": "arn:aws:sns:us-east-1:123456789012:topic_name",  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:prefix-*"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "123456789012"  
                }  
            }  
        }  
    ]  
}
```

Subscribing to Amazon RDS event notification

The simplest way to create a subscription is with the RDS console. If you choose to create event notification subscriptions using the CLI or API, you must create an Amazon Simple Notification Service topic and subscribe to that topic with the Amazon SNS console or Amazon SNS API. You will also need to retain the Amazon Resource Name (ARN) of the topic because it is used when submitting CLI commands or API operations. For information on creating an SNS topic and subscribing to it, see [Getting started with Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide*.

You can specify the type of source you want to be notified of and the Amazon RDS source that triggers the event:

Source type

The type of source. For example, **Source type** might be **Instances**. You must choose a source type.

Resources to include

The Amazon RDS resources that are generating the events. For example, you might choose **Select specific instances** and then **myDBInstance1**.

The following table explains the result when you specify or don't specify **Resources to include**.

Resources to include	Description	Example
Specified	RDS notifies you about all events for the specified resource only.	If your Source type is Instances and your resource is myDBInstance1 , RDS notifies you about all events for myDBInstance1 only.
Not specified	RDS notifies you about the events for the specified source type for all your Amazon RDS resources.	If your Source type is Instances , RDS notifies you about all instance-related events in your account.

Console

To subscribe to RDS event notification

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In navigation pane, choose **Event subscriptions**.
3. In the **Event subscriptions** pane, choose **Create event subscription**.
4. Enter your subscription details as follows:
 - a. For **Name**, enter a name for the event notification subscription.
 - b. For **Send notifications to**, do one of the following:
 - Choose **New email topic**. Enter a name for your email topic and a list of recipients.
 - Choose **Amazon Resource Name (ARN)**. Then choose existing Amazon SNS ARN for an Amazon SNS topic.

If you want to use a topic that has been enabled for server-side encryption (SSE), grant Amazon RDS the necessary permissions to access the AWS KMS key. For more information, see

Enable compatibility between event sources from AWS services and encrypted topics in the *Amazon Simple Notification Service Developer Guide*.

- c. For **Source type**, choose a source type. For example, choose **Instances** or **Parameter groups**.
- d. Choose the event categories and resources that you want to receive event notifications for.

The following example configures event notifications for the DB instance named testinst.

The screenshot shows the 'Source' configuration dialog. It includes fields for 'Source type' (set to 'Instances'), 'Instances to include' (set to 'Select specific instances' with 'testinst' selected), and 'Event categories to include' (set to 'All event categories').

- e. Choose **Create**.

The Amazon RDS console indicates that the subscription is being created.

Event subscriptions (2)				
		Edit	Delete	Create event subscription
<input type="text"/> Filter event subscriptions				
Name	Status	Source Type	Enabled	
Configchangerdpgres	active	Instances	Yes	
Test	creating	Instances	Yes	

AWS CLI

To subscribe to RDS event notification, use the AWS CLI [create-event-subscription](#) command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

Example

For Linux, macOS, or Unix:

```
aws rds create-event-subscription \
--subscription-name myeventsSubscription \
--sns-topic-arn arn:aws:sns:us-east-1:123456789012:myawsuser-RDS \
--enabled
```

For Windows:

```
aws rds create-event-subscription ^
--subscription-name myeventsubscription ^
--sns-topic-arn arn:aws:sns:us-east-1:123456789012:myawsuser-RDS ^
--enabled
```

API

To subscribe to Amazon RDS event notification, call the Amazon RDS API function [CreateEventSubscription](#). Include the following required parameters:

- `SubscriptionName`
- `SnsTopicArn`

Listings Amazon RDS event notification subscriptions

You can list your current Amazon RDS event notification subscriptions.

Console

To list your current Amazon RDS event notification subscriptions

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Event subscriptions**. The **Event subscriptions** pane shows all your event notification subscriptions.

Event subscriptions (2)		
	Name	Status
<input type="checkbox"/> <input type="checkbox"/> Filter event subscriptions		
<input type="checkbox"/>	Configchangerdpgres	active
<input type="checkbox"/>	Postgresnotification	active

AWS CLI

To list your current Amazon RDS event notification subscriptions, use the AWS CLI [describe-event-subscriptions](#) command.

Example

The following example describes all event subscriptions.

```
aws rds describe-event-subscriptions
```

The following example describes the *myfirsteventsubscription*.

```
aws rds describe-event-subscriptions --subscription-name myfirsteventsubscription
```

API

To list your current Amazon RDS event notification subscriptions, call the Amazon RDS API [DescribeEventSubscriptions](#) action.

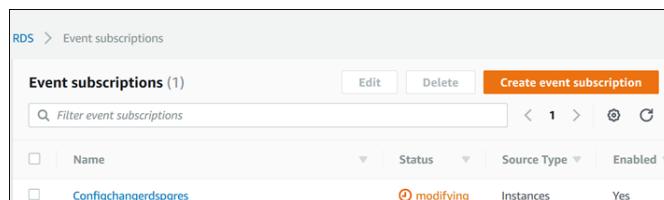

Modifying an Amazon RDS event notification subscription

After you have created a subscription, you can change the subscription name, source identifier, categories, or topic ARN.

Console

To modify an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Event subscriptions**.
3. In the **Event subscriptions** pane, choose the subscription that you want to modify and choose **Edit**.
4. Make your changes to the subscription in either the **Target** or **Source** section.
5. Choose **Edit**. The Amazon RDS console indicates that the subscription is being modified.

AWS CLI

To modify an Amazon RDS event notification subscription, use the AWS CLI `modify-event-subscription` command. Include the following required parameter:

- `--subscription-name`

Example

The following code enables `myeventsSubscription`.

For Linux, macOS, or Unix:

```
aws rds modify-event-subscription \
--subscription-name myeventsSubscription \
--enabled
```

For Windows:

```
aws rds modify-event-subscription ^
--subscription-name myeventsSubscription ^
--enabled
```

API

To modify an Amazon RDS event, call the Amazon RDS API operation `ModifyEventSubscription`. Include the following required parameter:

- `SubscriptionName`

Adding a source identifier to an Amazon RDS event notification subscription

You can add a source identifier (the Amazon RDS source generating the event) to an existing subscription.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see [Modifying an Amazon RDS event notification subscription \(p. 659\)](#).

AWS CLI

To add a source identifier to an Amazon RDS event notification subscription, use the AWS CLI [add-source-identifier-to-subscription](#) command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

Example

The following example adds the source identifier `mysqldb` to the `myrdseventsSubscription` subscription.

For Linux, macOS, or Unix:

```
aws rds add-source-identifier-to-subscription \
  --subscription-name myrdseventsSubscription \
  --source-identifier mysqldb
```

For Windows:

```
aws rds add-source-identifier-to-subscription ^
  --subscription-name myrdseventsSubscription ^
  --source-identifier mysqldb
```

API

To add a source identifier to an Amazon RDS event notification subscription, call the Amazon RDS API [AddSourceIdentifierToSubscription](#). Include the following required parameters:

- `SubscriptionName`
- `SourceIdentifier`

Removing a source identifier from an Amazon RDS event notification subscription

You can remove a source identifier (the Amazon RDS source generating the event) from a subscription if you no longer want to be notified of events for that source.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see [Modifying an Amazon RDS event notification subscription \(p. 659\)](#).

AWS CLI

To remove a source identifier from an Amazon RDS event notification subscription, use the AWS CLI `remove-source-identifier-from-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

Example

The following example removes the source identifier `mysql ldb` from the `myrdseventssubscription` subscription.

For Linux, macOS, or Unix:

```
aws rds remove-source-identifier-from-subscription \
  --subscription-name myrdseventssubscription \
  --source-identifier mysql ldb
```

For Windows:

```
aws rds remove-source-identifier-from-subscription ^
  --subscription-name myrdseventssubscription ^
  --source-identifier mysql ldb
```

API

To remove a source identifier from an Amazon RDS event notification subscription, use the Amazon RDS API `RemoveSourceIdentifierFromSubscription` command. Include the following required parameters:

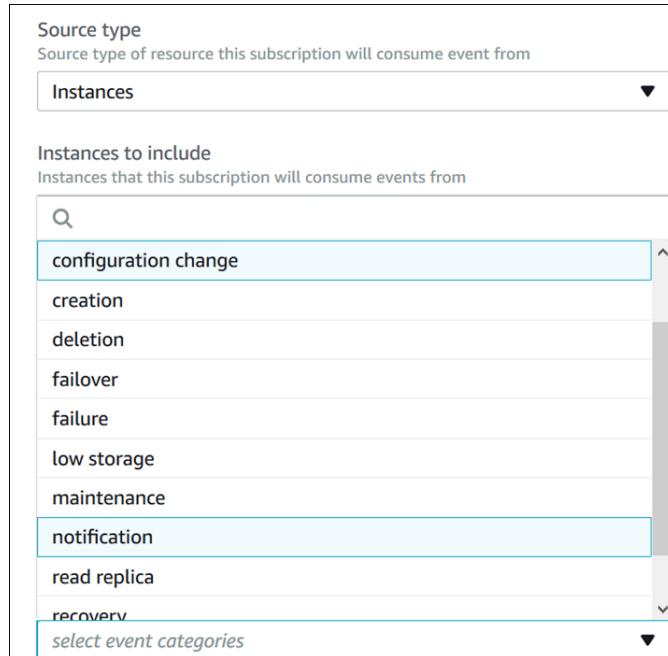

- `SubscriptionName`
- `SourceIdentifier`

List the Amazon RDS event notification categories

All events for a resource type are grouped into categories. To view the list of categories available, use the following procedures.

Console

When you create or modify an event notification subscription, the event categories are displayed in the Amazon RDS console. For more information, see [Modifying an Amazon RDS event notification subscription \(p. 659\)](#).

AWS CLI

To list the Amazon RDS event notification categories, use the AWS CLI [describe-event-categories](#) command. This command has no required parameters.

Example

```
aws rds describe-event-categories
```

API

To list the Amazon RDS event notification categories, use the Amazon RDS API [DescribeEventCategories](#) command. This command has no required parameters.

Deleting an Amazon RDS event notification subscription

You can delete a subscription when you no longer need it. All subscribers to the topic will no longer receive event notifications specified by the subscription.

Console

To delete an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **DB Event Subscriptions**.
3. In the **My DB Event Subscriptions** pane, choose the subscription that you want to delete.
4. Choose **Delete**.
5. The Amazon RDS console indicates that the subscription is being deleted.

The screenshot shows the 'Event subscriptions' section of the Amazon RDS console. It displays two entries in a table:

Name	Status
Configchangerdspgres	active
Postgresnotification	active

At the top of the table, there is a 'Delete' button which has been circled in red.

AWS CLI

To delete an Amazon RDS event notification subscription, use the AWS CLI [delete-event-subscription](#) command. Include the following required parameter:

- `--subscription-name`

Example

The following example deletes the subscription `myrdssubscription`.

```
aws rds delete-event-subscription --subscription-name myrdssubscription
```

API

To delete an Amazon RDS event notification subscription, use the RDS API [DeleteEventSubscription](#) command. Include the following required parameter:

- `SubscriptionName`

Creating a rule that triggers on an Amazon RDS event

Using Amazon CloudWatch Events and Amazon EventBridge, you can automate AWS services and respond to system events such as application availability issues or resource changes.

Topics

- [Creating rules to send Amazon RDS events to CloudWatch Events \(p. 664\)](#)
- [Tutorial: Log DB instance state changes using Amazon EventBridge \(p. 665\)](#)

Creating rules to send Amazon RDS events to CloudWatch Events

You can write simple rules to indicate which Amazon RDS events interest you and which automated actions to take when an event matches a rule. You can set a variety of targets, such as an AWS Lambda function or an Amazon SNS topic, which receive events in JSON format. For example, you can configure Amazon RDS to send events to CloudWatch Events or Amazon EventBridge whenever a DB instance is created or deleted. For more information, see the [Amazon CloudWatch Events User Guide](#) and the [Amazon EventBridge User Guide](#).

To create a rule that triggers on an RDS event:

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Under **Events** in the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. For **Event Source**, do the following:
 - a. Choose **Event Pattern**.
 - b. For **Service Name**, choose **Relational Database Service (RDS)**.
 - c. For **Event Type**, choose the type of Amazon RDS resource that triggers the event. For example, if a DB instance triggers the event, choose **RDS DB Instance Event**.
5. For **Targets**, choose **Add Target** and choose the AWS service that is to act when an event of the selected type is detected.
6. In the other fields in this section, enter information specific to this target type, if any is needed.
7. For many target types, CloudWatch Events needs permissions to send events to the target. In these cases, CloudWatch Events can create the IAM role needed for your event to run:
 - To create an IAM role automatically, choose **Create a new role for this specific resource**.
 - To use an IAM role that you created before, choose **Use existing role**.
8. Optionally, repeat steps 5-7 to add another target for this rule.
9. Choose **Configure details**. For **Rule definition**, type a name and description for the rule.

The rule name must be unique within this Region.

10. Choose **Create rule**.

For more information, see [Creating a CloudWatch Events Rule That Triggers on an Event](#) in the *Amazon CloudWatch User Guide*.

Tutorial: Log DB instance state changes using Amazon EventBridge

In this tutorial, you create an AWS Lambda function that logs the state changes for an Amazon RDS instance. You then create a rule that runs the function whenever there is a state change of an existing RDS DB instance. The tutorial assumes that you have a small running test instance that you can shut down temporarily.

Important

Don't perform this tutorial on a running production DB instance.

Topics

- [Step 1: Create an AWS Lambda function \(p. 665\)](#)
- [Step 2: Create a rule \(p. 666\)](#)
- [Step 3: Test the rule \(p. 666\)](#)

Step 1: Create an AWS Lambda function

Create a Lambda function to log the state change events. You specify this function when you create your rule.

To create a Lambda function

1. Open the AWS Lambda console at <https://console.aws.amazon.com/lambda/>.
2. If you're new to Lambda, you see a welcome page. Choose **Get Started Now**. Otherwise, choose **Create function**.
3. Choose **Author from scratch**.
4. On the **Create function** page, do the following:
 - a. Enter a name and description for the Lambda function. For example, name the function **RDSInstanceStateChange**.
 - b. In **Runtime**, select **Node.js 16x**.
 - c. For **Architecture**, choose **x86_64**.
 - d. For **Execution role**, do either of the following:
 - Choose **Create a new role with basic Lambda permissions**.
 - For **Existing role**, choose **Use an existing role**. Choose the role that you want to use.
 - e. Choose **Create function**.
5. On the **RDSInstanceStateChange** page, do the following:
 - a. In **Code source**, select **index.js**.
 - b. In the **index.js** pane, delete the existing code.
 - c. Enter the following code:

```
console.log('Loading function');

exports.handler = async (event, context) => {
    console.log('Received event:', JSON.stringify(event));
};
```

- d. Choose **Deploy**.

Step 2: Create a rule

Create a rule to run your Lambda function whenever you launch an Amazon RDS instance.

To create the EventBridge rule

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule. For example, enter **RDSInstanceStateChangeRule**.
5. Choose **Rule with an event pattern**, and then choose **Next**.
6. For **Event source**, choose **AWS events or EventBridge partner events**.
7. Scroll down to the **Event pattern** section.
8. For **Event source**, choose **AWS services**.
9. For **AWS service**, choose **Relational Database Service (RDS)**.
10. For **Event type**, choose **RDS DB Instance Event**.
11. Leave the default event pattern. Then choose **Next**.
12. For **Target types**, choose **AWS service**.
13. For **Select a target**, choose **Lambda function**.
14. For **Function**, choose the Lambda function that you created. Then choose **Next**.
15. In **Configure tags**, choose **Next**.
16. Review the steps in your rule. Then choose **Create rule**.

Step 3: Test the rule

To test your rule, shut down an RDS DB instance. After waiting a few minutes for the instance to shut down, verify that your Lambda function was invoked.

To test your rule by stopping a DB instance

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Stop an RDS DB instance.
3. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
4. In the navigation pane, choose **Rules**, choose the name of the rule that you created.
5. In **Rule details**, choose **Metrics for the rule**.

You are redirected to the Amazon CloudWatch console.
6. In **All metrics**, choose the name of the rule that you created.

The graph should indicate that the rule was invoked.
7. In the navigation pane, choose **Log groups**.
8. Choose the name of the log group for your Lambda function (`/aws/lambda/function-name`).
9. Choose the name of the log stream to view the data provided by the function for the instance that you launched. You should see a received event similar to the following:

```
{  
  "version": "0",  
  "id": "12a345b6-78c9-01d2-34e5-123f4ghi5j6k",  
  "detail-type": "RDS DB Instance Event",  
  "source": "aws.rds",  
  "account": "111111111111",  
  "time": "2021-03-19T19:34:09Z",  
  "region": "us-east-1",  
  "resources": ["arn:aws:rds:us-east-1:111111111111:db:mydb"]}
```

```
"region": "us-east-1",
"resources": [
    "arn:aws:rds:us-east-1:111111111111:db:testdb"
],
"detail": {
    "EventCategories": [
        "notification"
    ],
    "SourceType": "DB_INSTANCE",
    "SourceArn": "arn:aws:rds:us-east-1:111111111111:db:testdb",
    "Date": "2021-03-19T19:34:09.293Z",
    "Message": "DB instance stopped",
    "SourceIdentifier": "testdb",
    "EventID": "RDS-EVENT-0087"
}
}
```

For more examples of RDS events in JSON format, see [Overview of events for Amazon RDS \(p. 646\)](#).

10. (Optional) When you're finished, you can open the Amazon RDS console and start the instance that you stopped.

Amazon RDS event categories and event messages

Amazon RDS generates a significant number of events in categories that you can subscribe to using the Amazon RDS Console, AWS CLI, or the API.

Topics

- [DB cluster events \(p. 668\)](#)
- [DB instance events \(p. 669\)](#)
- [DB parameter group events \(p. 676\)](#)
- [DB security group events \(p. 676\)](#)
- [DB snapshot events \(p. 677\)](#)
- [DB cluster snapshot events \(p. 678\)](#)
- [RDS Proxy events \(p. 678\)](#)
- [Custom engine version events \(p. 679\)](#)
- [Message attributes \(p. 679\)](#)

DB cluster events

The following table shows the event category and a list of events when a DB cluster is the source type.

For more information about Multi-AZ DB cluster deployments, see [Multi-AZ DB cluster deployments \(p. 127\)](#)

Category	RDS event ID	Description
creation	RDS-EVENT-0170	DB cluster created.
failover	RDS-EVENT-0069	A failover for the DB cluster has failed.
failover	RDS-EVENT-0070	A failover for the DB cluster has restarted.
failover	RDS-EVENT-0071	A failover for the DB cluster has finished.
failover	RDS-EVENT-0072	A failover for the DB cluster has begun within the same Availability Zone.
failover	RDS-EVENT-0073	A failover for the DB cluster has begun across Availability Zones.
global failover	RDS-EVENT-0181	The failover of the global database has started. The process can be delayed because other operations are running on the DB cluster.
global failover	RDS-EVENT-0182	The old primary instance in the global database isn't accepting writes. All volumes are synchronized.
global failover	RDS-EVENT-0183	A replication lag is occurring during the synchronization phase of the global database failover.
global failover	RDS-EVENT-0184	The volume topology of the global database is reestablished with the new primary volume.
global failover	RDS-EVENT-0185	The global database failover is finished on the primary DB cluster. Replicas might take long to come online after the failover completes.

Category	RDS event ID	Description
global failover	RDS-EVENT-0186	The global database failover is canceled.
global failover	RDS-EVENT-0187	The global failover to the DB cluster failed.

DB instance events

The following table shows the event category and a list of events when a DB instance is the source type.

Category	RDS event ID	Description
availability	RDS-EVENT-0006	The DB instance restarted.
availability	RDS-EVENT-0004	DB instance shutdown.
availability	RDS-EVENT-0022	An error has occurred while restarting MySQL.
availability	RDS-EVENT-0221	The DB instance has reached the storage-full threshold, and the database has been shut down. You can increase the allocated storage to address this issue.
availability	RDS-EVENT-0222	Free storage capacity for DB instance [instance name] is low at [percentage]% of the allocated storage (allocated storage: [value], free storage: [value]). The database will be shut down to prevent corruption if free storage is lower than [value]. You can increase the allocated storage to address this issue.
backup	RDS-EVENT-0001	Backing up the DB instance.
backup	RDS-EVENT-0002	Finished DB Instance backup.
backup	RDS-EVENT-0086	RDS was unable to associate the option group with the database instance. Confirm that the option group is supported on your DB instance class and configuration. For more information see Working with option groups (p. 273) .
configuration change	RDS-EVENT-0009	The DB instance has been added to a security group.
configuration change	RDS-EVENT-0024	The DB instance is being converted to a Multi-AZ DB instance.
configuration change	RDS-EVENT-0030	The DB instance is being converted to a Single-AZ DB instance.
configuration change	RDS-EVENT-0012	Applying modification to database instance class.
configuration change	RDS-EVENT-0018	The current storage settings for this DB instance are being changed.
configuration change	RDS-EVENT-0011	A parameter group for this DB instance has changed.

Category	RDS event ID	Description
configuration change	RDS-EVENT-0092	A parameter group for this DB instance has finished updating.
configuration change	RDS-EVENT-0028	Automatic backups for this DB instance have been disabled.
configuration change	RDS-EVENT-0032	Automatic backups for this DB instance have been enabled.
configuration change	RDS-EVENT-0033	There are [count] users that match the master user name. Users not tied to a specific host have been reset.
configuration change	RDS-EVENT-0025	The DB instance has been converted to a Multi-AZ DB instance.
configuration change	RDS-EVENT-0029	The DB instance has been converted to a Single-AZ DB instance.
configuration change	RDS-EVENT-0014	The DB instance class for this DB instance has changed.
configuration change	RDS-EVENT-0017	The storage settings for this DB instance have changed.
configuration change	RDS-EVENT-0010	The DB instance has been removed from a security group.
configuration change	RDS-EVENT-0016	The master password for the DB instance has been reset.
configuration change	RDS-EVENT-0067	An attempt to reset the master password for the DB instance has failed.
configuration change	RDS-EVENT-0078	The Enhanced Monitoring configuration has been changed.
configuration change	RDS-EVENT-0217	Applying autoscaling-initiated modification to allocated storage.
configuration change	RDS-EVENT-0218	Finished applying autoscaling-initiated modification to allocated storage.
creation	RDS-EVENT-0005	DB instance created.
deletion	RDS-EVENT-0003	The DB instance has been deleted.
failover	RDS-EVENT-0013	A Multi-AZ failover that resulted in the promotion of a standby instance has started.
failover	RDS-EVENT-0015	A Multi-AZ failover that resulted in the promotion of a standby instance is complete. It may take several minutes for the DNS to transfer to the new primary DB instance.
failover	RDS-EVENT-0034	Amazon RDS is not attempting a requested failover because a failover recently occurred on the DB instance.

Category	RDS event ID	Description
failover	RDS-EVENT-0049	A Multi-AZ failover has completed.
failover	RDS-EVENT-0050	A Multi-AZ activation has started after a successful instance recovery.
failover	RDS-EVENT-0051	A Multi-AZ activation is complete. Your database should be accessible now.
failover	RDS-EVENT-0065	The instance has recovered from a partial failover.
failure	RDS-EVENT-0031	The DB instance has failed due to an incompatible configuration or an underlying storage issue. Begin a point-in-time-restore for the DB instance.
failure	RDS-EVENT-0035	The DB instance has invalid parameters. For example, if the DB instance could not start because a memory-related parameter is set too high for this instance class, the customer action would be to modify the memory parameter and reboot the DB instance.
failure	RDS-EVENT-0036	The DB instance is in an incompatible network. Some of the specified subnet IDs are invalid or do not exist.
failure	RDS-EVENT-0058	Error while creating Statspack user account PERFSTAT. Drop the account before you add the Statspack option.
failure	RDS-EVENT-0079	Enhanced Monitoring cannot be enabled without the enhanced monitoring IAM role. For information on creating the enhanced monitoring IAM role, see To create an IAM role for Amazon RDS enhanced monitoring (p. 602) .
failure	RDS-EVENT-0080	Enhanced Monitoring was disabled due to an error making the configuration change. It is likely that the enhanced monitoring IAM role is configured incorrectly. For information on creating the enhanced monitoring IAM role, see To create an IAM role for Amazon RDS enhanced monitoring (p. 602) .
failure	RDS-EVENT-0081	The IAM role that you use to access your Amazon S3 bucket for SQL Server native backup and restore is configured incorrectly. For more information, see Setting up for native backup and restore (p. 1101) .
failure	RDS-EVENT-0165	The RDS Custom DB instance is outside the support perimeter.
failure	RDS-EVENT-0188	Amazon RDS was unable to upgrade a MySQL DB instance from version 5.7 to version 8.0 because of incompatibilities related to the data dictionary. The DB instance was rolled back to MySQL version 5.7. For more information, see Rollback after failure to upgrade from MySQL 5.7 to 8.0 (p. 1347) .
failure	RDS-EVENT-0219	The DB instance is in an invalid state. No actions are necessary. Autoscaling will retry later.

Category	RDS event ID	Description
failure	RDS-EVENT-0220	The DB instance is in the cooling-off period for a previous scale storage operation. We are optimizing your instance. This takes at least six hours. No actions are necessary. Autoscaling will retry after the cooling-off period.
failure	RDS-EVENT-0223	Storage autoscaling is unable to scale the storage for the reason: [reason].
failure	RDS-EVENT-0224	Storage autoscaling has triggered a pending scale storage task that would reach the maximum storage threshold. Increase the maximum storage threshold.
failure	RDS-EVENT-0237	The DB instance has a storage type that's currently unavailable in the Availability Zone. Autoscaling will retry later.
failure	RDS-EVENT-0254	The storage for your AWS account has exceeded the allowed storage quota. Increase the quota to let the autoscaling operation proceed.
low storage	RDS-EVENT-0007	The allocated storage for the DB instance has been consumed. To resolve this issue, allocate additional storage for the DB instance. For more information, see the RDS FAQ . You can monitor the storage space for a DB instance using the Free Storage Space metric.
low storage	RDS-EVENT-0089	The DB instance has consumed more than 90% of its allocated storage. You can monitor the storage space for a DB instance using the Free Storage Space metric.
low storage	RDS-EVENT-0227	The Aurora storage subsystem is running low on space.
maintenance	RDS-EVENT-0026	Offline maintenance of the DB instance is taking place. The DB instance is currently unavailable.
maintenance	RDS-EVENT-0027	Offline maintenance of the DB instance is complete. The DB instance is now available.
maintenance	RDS-EVENT-0047	The DB instance was patched.
maintenance	RDS-EVENT-0155	The DB instance has a DB engine minor version upgrade required.
maintenance, notification	RDS-EVENT-0191	An Oracle time zone file update is available. If you update your Oracle engine, Amazon RDS generates this event if you haven't chosen a time zone file upgrade and the database doesn't use the latest DST time zone file available on the instance. For more information, see Oracle time zone file autoupgrade (p. 1746) .

Category	RDS event ID	Description
maintenance, notification	RDS-EVENT-0192	<p>The upgrade of your Oracle time zone file has begun.</p> <p>For more information, see Oracle time zone file autoupgrade (p. 1746).</p>
maintenance, notification	RDS-EVENT-0193	<p>Your Oracle DB instance is using latest time zone file version, and either of the following is true:</p> <ul style="list-style-type: none"> • You recently added the TIMEZONE_FILE_AUTOUPGRADE option. • Your Oracle DB engine is being upgraded. <p>For more information, see Oracle time zone file autoupgrade (p. 1746).</p>
maintenance, notification	RDS-EVENT-0194	<p>The upgrade of your Oracle time zone file has completed.</p> <p>For more information, see Oracle time zone file autoupgrade (p. 1746).</p>
maintenance, failure	RDS-EVENT-0195	<p>The upgrade of the time zone file failed.</p> <p>For more information, see Oracle time zone file autoupgrade (p. 1746).</p>
notification	RDS-EVENT-0044	Operator-issued notification. For more information, see the event message.
notification	RDS-EVENT-0048	Patching of the DB instance has been delayed.
notification	RDS-EVENT-0054	The MySQL storage engine you are using is not InnoDB, which is the recommended MySQL storage engine for Amazon RDS. For information about MySQL storage engines, see Supported storage engines for RDS for MySQL (p. 1312) .
notification	RDS-EVENT-0055	<p>The number of tables you have for your DB instance exceeds the recommended best practices for Amazon RDS. Reduce the number of tables on your DB instance.</p> <p>For information about recommended best practices, see Amazon RDS basic operational guidelines (p. 216).</p>
notification	RDS-EVENT-0056	<p>The number of databases you have for your DB instance exceeds the recommended best practices for Amazon RDS. Reduce the number of databases on your DB instance.</p> <p>For information about recommended best practices, see Amazon RDS basic operational guidelines (p. 216).</p>
notification	RDS-EVENT-0064	The TDE key has been rotated. For information about recommended best practices, see Amazon RDS basic operational guidelines (p. 216) .

Category	RDS event ID	Description
notification	RDS-EVENT-0084	You attempted to convert a DB instance to Multi-AZ, but it contains in-memory file groups that are not supported for Multi-AZ. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 1129) .
notification	RDS-EVENT-0087	The DB instance has been stopped.
notification	RDS-EVENT-0088	The DB instance has been started.
notification	RDS-EVENT-0154	The DB instance is being started due to it exceeding the maximum allowed time being stopped.
notification	RDS-EVENT-0157	RDS can't modify the DB instance class because the target instance class can't support the number of databases that exist on the source DB instance. The error message appears as: "The instance has <i>N</i> databases, but after conversion it would only support <i>N</i> ". For more information, see Limitations for Microsoft SQL Server DB instances (p. 1060) .
notification	RDS-EVENT-0158	DB instance is in a state that can't be upgraded.
notification	RDS-EVENT-0167	The RDS Custom support perimeter configuration has changed.
notification	RDS-EVENT-0189	The gp2 burst balance credits for the RDS database instance are low. To resolve this issue, reduce IOPS usage or modify your storage settings to enable higher performance. For more information, see I/O credits and burst performance in the Amazon Elastic Compute Cloud User Guide .
notification	RDS-EVENT-0225	Storage size [value] GB is approaching the maximum storage threshold [value] GB. This event is invoked when storage reaches 80% of the maximum storage threshold. To avoid the event, increase the maximum storage threshold.
notification	RDS-EVENT-0231	Your DB instance's storage modification encountered an internal error. The modification request is pending and will be retried later.

Category	RDS event ID	Description
read replica	RDS-EVENT-0045	<p>An error has occurred in the read replication process. For more information, see the event message.</p> <p>In addition, see the troubleshooting section for read replicas for your DB engine.</p> <ul style="list-style-type: none"> • Troubleshooting a MariaDB read replica problem (p. 1033) • Troubleshooting a SQL Server read replica problem (p. 1128) • Troubleshooting a MySQL read replica problem (p. 1399) • Troubleshooting RDS for Oracle replicas (p. 1644)
read replica	RDS-EVENT-0046	The read replica has resumed replication. This message appears when you first create a read replica, or as a monitoring message confirming that replication is functioning properly. If this message follows an RDS-EVENT-0045 notification, then replication has resumed following an error or after replication was stopped.
read replica	RDS-EVENT-0057	Replication on the read replica was terminated.
read replica	RDS-EVENT-0062	Replication on the read replica was manually stopped.
read replica	RDS-EVENT-0063	Replication on the read replica was reset.
read replica	RDS-EVENT-0202	Read replica creation failed.
recovery	RDS-EVENT-0020	Recovery of the DB instance has started. Recovery time will vary with the amount of data to be recovered.
recovery	RDS-EVENT-0021	Recovery of the DB instance is complete.
recovery	RDS-EVENT-0023	A manual backup has been requested but Amazon RDS is currently in the process of creating a DB snapshot. Submit the request again after Amazon RDS has completed the DB snapshot.
recovery	RDS-EVENT-0052	Recovery of the Multi-AZ instance has started. Recovery time will vary with the amount of data to be recovered.
recovery	RDS-EVENT-0053	Recovery of the Multi-AZ instance is complete.
recovery	RDS-EVENT-0066	The SQL Server DB instance is re-establishing its mirror. Performance will be degraded until the mirror is reestablished. A database was found with non-FULL recovery model. The recovery model was changed back to FULL and mirroring recovery was started. (<dbname>: <recovery model found>[,...])"
recovery	RDS-EVENT-0166	The RDS Custom DB instance is inside the support perimeter.

Category	RDS event ID	Description
restoration	RDS-EVENT-0019	The DB instance has been restored from a point-in-time backup.
restoration	RDS-EVENT-0043	Restored from snapshot [snapshot_name]. The DB instance has been restored from a DB snapshot.
security	RDS-EVENT-0068	RDS is decrypting the CloudHSM partition password to make updates to the instance. For more information see Oracle Database Transparent Data Encryption (TDE) with AWS CloudHSM in the AWS CloudHSM User Guide .
security patching	RDS-EVENT-0230	A system update is available for your DB instance. For information about applying updates, see Maintaining a DB instance (p. 350) .

DB parameter group events

The following table shows the event category and a list of events when a DB parameter group is the source type.

Category	RDS event ID	Description
configuration change	RDS-EVENT-0011	Updated to use DBParameterGroup <i>name</i> .
configuration change	RDS-EVENT-0092	Finished updating DB parameter group.

DB security group events

The following table shows the event category and a list of events when a DB security group is the source type.

Note

DB security groups are resources for EC2-Classic. EC2-Classic was retired on August 15, 2022. If you haven't migrated from EC2-Classic to a VPC, we recommend that you migrate as soon as possible. For more information, see [Migrate from EC2-Classic to a VPC](#) in the [Amazon EC2 User Guide](#) and the blog [EC2-Classic Networking is Retiring – Here's How to Prepare](#).

Category	RDS event ID	Description
configuration change	RDS-EVENT-0038	The security group has been modified.
failure	RDS-EVENT-0039	The security group owned by [user] does not exist. Authorization for the security group has been revoked.

DB snapshot events

The following table shows the event category and a list of events when a DB snapshot is the source type.

Category	RDS event ID	Description
creation	RDS-EVENT-0040	A manual DB snapshot is being created.
creation	RDS-EVENT-0042	A manual DB snapshot has been created.
creation	RDS-EVENT-0090	An automated DB snapshot is being created.
creation	RDS-EVENT-0091	An automated DB snapshot has been created.
deletion	RDS-EVENT-0041	A DB snapshot has been deleted.
notification	RDS-EVENT-0059	Started copy of snapshot [DB snapshot name] from region [region name]. Note This is a cross-Region snapshot copy.
notification	RDS-EVENT-0060	Finished copy of snapshot [DB snapshot name] from region [region name] in [time] minutes. Note This is a cross-Region snapshot copy.
notification	RDS-EVENT-0061	Canceled snapshot copy request of [DB snapshot name] from region [region name]. Note This is a cross-Region snapshot copy.
notification	RDS-EVENT-0159	The DB snapshot export task failed.
notification	RDS-EVENT-0160	The DB snapshot export task was canceled.
notification	RDS-EVENT-0161	The DB snapshot export task completed.
notification	RDS-EVENT-0196	Started copy of snapshot [DB snapshot name] in region [region name]. Note This is a local snapshot copy.
notification	RDS-EVENT-0197	Finished copy of snapshot [DB snapshot name] in region [region name]. Note This is a local snapshot copy.
notification	RDS-EVENT-0190	Canceled snapshot copy request of [DB snapshot name] in region [region name]. Note This is a local snapshot copy.
restoration	RDS-EVENT-0043	Restored from snapshot [snapshot_name]. A DB instance is being restored from a DB snapshot.

DB cluster snapshot events

The following table shows the event category and a list of events when a DB cluster snapshot is the source type.

Category	RDS event ID	Description
backup	RDS-EVENT-0074	Creation of a manual DB cluster snapshot has started.
backup	RDS-EVENT-0075	A manual DB cluster snapshot has been created.
backup	RDS-EVENT-0168	Creating automated cluster snapshot.
backup	RDS-EVENT-0169	Automated cluster snapshot created.
notification	RDS-EVENT-0172	Renamed DB cluster from [old DB cluster name] to [new DB cluster name].

RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

Category	RDS event ID	Description
configuration change	RDS-EVENT-0204	RDS modified the DB proxy (RDS Proxy).
configuration change	RDS-EVENT-0207	RDS modified the endpoint of the DB proxy (RDS Proxy).
configuration change	RDS-EVENT-0213	RDS detected the addition of the DB instance and automatically added it to the target group of the DB proxy (RDS Proxy).
configuration change	RDS-EVENT-0214	RDS detected the deletion of the DB instance and automatically removed it from the target group of the DB proxy (RDS Proxy).
configuration change	RDS-EVENT-0215	RDS detected the deletion of the DB cluster and automatically removed it from the target group of the DB proxy (RDS Proxy).
creation	RDS-EVENT-0203	RDS created the DB proxy (RDS Proxy).
creation	RDS-EVENT-0206	RDS created the endpoint for the DB proxy (RDS Proxy).
deletion	RDS-EVENT-0205	RDS deleted the DB proxy (RDS Proxy).
deletion	RDS-EVENT-0208	RDS deleted the endpoint of DB proxy (RDS Proxy).
failure	RDS-EVENT-0243	RDS couldn't provision capacity for the proxy because there aren't enough IP addresses available in your subnets. To fix the issue, make sure that your subnets have the minimum number of unused IP addresses. To determine the recommended number

Category	RDS event ID	Description
		for your instance class, see Planning for IP address capacity (p. 930) .

Custom engine version events

The following table shows the event category and a list of events when a custom engine version is the source type.

Category	Amazon RDS event ID	Description
failure	RDS-EVENT-0198	Creation failed for custom engine version. The message includes details about the failure, such as missing files.

Message attributes

The following table shows the message attribute for RDS events.

Amazon RDS event attribute	Description
Event ID	Identifier for the RDS event message. For example, RDS-EVENT-0006.
Resource	The ARN identifier for the resource emitting the event. For example, arn:aws:rds:ap-southeast-2:123456789012:db:database-1.

Monitoring Amazon RDS log files

Every RDS database engine generates logs that you can access for auditing and troubleshooting. The type of logs depends on your database engine.

You can access database logs using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API. You can't view, watch, or download transaction logs.

Viewing and listing database log files

You can view database log files for your Amazon RDS DB engine by using the AWS Management Console. You can list what log files are available for download or monitoring by using the AWS CLI or Amazon RDS API.

Note

If you can't view the list of log files for an existing RDS for Oracle DB instance, reboot the instance to view the list.

Console

To view a database log file

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. (Optional) Enter a search term to filter your results.
7. Choose the log that you want to view, and then choose **View**.

AWS CLI

To list the available database log files for a DB instance, use the AWS CLI `describe-db-log-files` command.

The following example returns a list of log files for a DB instance named `my-db-instance`.

Example

```
aws rds describe-db-log-files --db-instance-identifier my-db-instance
```

RDS API

To list the available database log files for a DB instance, use the Amazon RDS API [DescribeDBLogFiles](#) action.

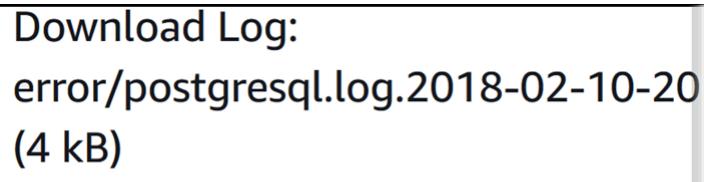

Downloading a database log file

You can use the AWS Management Console, AWS CLI, or API to download a database log file.

Console

To download a database log file

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, choose the button next to the log that you want to download, and then choose **Download**.
7. Open the context (right-click) menu for the link provided, and then choose **Save Link As**. Enter the location where you want the log file to be saved, and then choose **Save**.

AWS CLI

To download a database log file, use the AWS CLI command [download-db-log-file-portion](#). By default, this command downloads only the latest portion of a log file. However, you can download an entire file by specifying the parameter `--starting-token 0`.

The following example shows how to download the entire contents of a log file called *log/ERROR.4* and store it in a local file called *errorlog.txt*.

Example

For Linux, macOS, or Unix:

```
aws rds download-db-log-file-portion \
--db-instance-identifier myexampledb \
--starting-token 0 --output text \
--log-file-name log/ERROR.4 > errorlog.txt
```

For Windows:

```
aws rds download-db-log-file-portion ^
--db-instance-identifier myexampledb ^
--starting-token 0 --output text ^
--log-file-name log/ERROR.4 > errorlog.txt
```

RDS API

To download a database log file, use the Amazon RDS API [DownloadDBLogFilePortion](#) action.

Watching a database log file

Watching a database log file is equivalent to tailing the file on a UNIX or Linux system. You can watch a log file by using the AWS Management Console. RDS refreshes the tail of the log every 5 seconds.

To watch a database log file

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.

The screenshot shows the AWS RDS console interface. The top navigation bar includes 'RDS', 'Databases', and 'database-1'. On the right, there are 'Modify' and 'Actions' buttons. Below the navigation, the 'Logs & events' tab is highlighted with a red oval. The main area displays a summary table for the database instance 'database-1'. The table includes columns for DB identifier, CPU usage (2.53%), Status (Available), Class (db.m5.large), Role, Current activity (0.00 sessions), Engine (MariaDB), and Region & AZ (us-east-1d). At the bottom of the screen, tabs for 'Connectivity & security', 'Monitoring', 'Logs & events' (which is circled in red), 'Configuration', 'Maintenance & backups', and 'Tags' are visible.

5. In the **Logs** section, choose a log file, and then choose **Watch**.

The screenshot shows the 'Logs' section of the AWS RDS console. The top header says 'Logs (4)' and includes buttons for 'C', 'View', 'Watch', and 'Download'. A search bar labeled 'Filter by db events' is present. The main area lists four log files: 'error/mysql-error-running.log', 'error/mysql-error-running.log.2022-08-02.14', 'error/mysql-error.log', and 'mysqlUpgrade'. Each log entry includes the name, last written timestamp, and size. The second log file, 'error/mysql-error-running.log.2022-08-02.14', is selected and highlighted with a blue border. The 'Watch' button is located in the top right corner of the log list area.

RDS shows the tail of the log, as in the following MySQL example.

Watching Log: error/mysql-error-running.log.2022-08-02.14 (2.9 kB)

Publishing database logs to Amazon CloudWatch Logs

In an on-premises database, the database logs reside on the file system. Amazon RDS doesn't provide host access to the database logs on the file system of your DB instance. For this reason, Amazon RDS lets you export database logs to [Amazon CloudWatch Logs](#). With CloudWatch Logs, you can perform real-time analysis of the log data. You can also store the data in highly durable storage and manage the data with the CloudWatch Logs Agent.

Topics

- [Overview of RDS integration with CloudWatch Logs \(p. 683\)](#)
- [Deciding which logs to publish to CloudWatch Logs \(p. 684\)](#)
- [Specifying the logs to publish to CloudWatch Logs \(p. 684\)](#)
- [Searching and filtering your logs in CloudWatch Logs \(p. 684\)](#)

Overview of RDS integration with CloudWatch Logs

In CloudWatch Logs, a *log stream* is a sequence of log events that share the same source. Each separate source of logs in CloudWatch Logs makes up a separate log stream. A *log group* is a group of log streams that share the same retention, monitoring, and access control settings.

Amazon RDS continuously streams your DB instance log records to a log group. For example, you have a log group `/aws/rds/instance/instance_name/log_type` for each type of log that you publish. This log group is in the same AWS Region as the database instance that generates the log.

AWS retains log data published to CloudWatch Logs for an indefinite time period unless you specify a retention period. For more information, see [Change log data retention in CloudWatch Logs](#).

Deciding which logs to publish to CloudWatch Logs

Each RDS database engine supports its own set of logs. To learn about the options for your database engine, review the following topics:

- the section called “Publishing MariaDB logs to Amazon CloudWatch Logs” (p. 689)
- the section called “Publishing MySQL logs to Amazon CloudWatch Logs” (p. 703)
- the section called “Publishing Oracle logs to Amazon CloudWatch Logs” (p. 712)
- the section called “Publishing PostgreSQL logs to Amazon CloudWatch Logs” (p. 721)
- the section called “Publishing SQL Server logs to Amazon CloudWatch Logs” (p. 696)

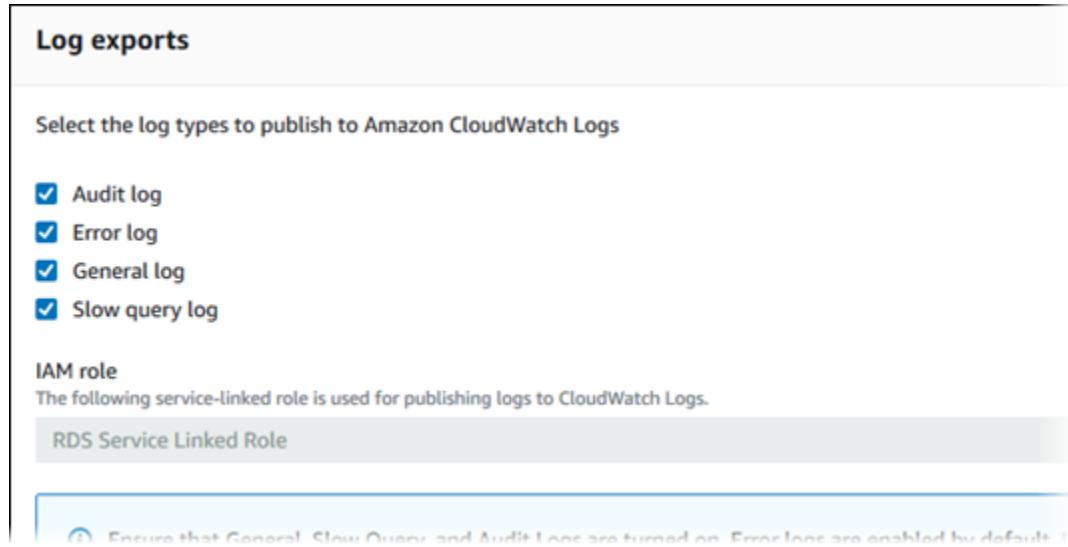

Specifying the logs to publish to CloudWatch Logs

You specify which logs to publish in the console. Make sure that you have a service-linked role in AWS Identity and Access Management (IAM). For more information about service-linked roles, see [Using service-linked roles for Amazon RDS \(p. 2089\)](#).

To specify the logs to publish

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Do either of the following:
 - Choose **Create database**.
 - Choose a database from the list, and then choose **Modify**.
4. In **Logs exports**, choose which logs to publish.

The following example specifies the audit log, error logs, general log, and slow query log.

Searching and filtering your logs in CloudWatch Logs

You can search for log entries that meet a specified criteria using the CloudWatch Logs console. You can access the logs either through the RDS console, which leads you to the CloudWatch Logs console, or from the CloudWatch Logs console directly.

To search your RDS logs using the RDS console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose a DB instance.
4. Choose **Configuration**.
5. Under **Published logs**, choose the database log that you want to view.

To search your RDS logs using the CloudWatch Logs console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Log groups**.
3. In the filter box, enter **/aws/rds**.
4. For **Log Groups**, choose the name of the log group containing the log stream to search.
5. For **Log Streams**, choose the name of the log stream to search.
6. Under **Log events**, enter the filter syntax to use.

For more information, see [Searching and filtering log data](#) in the *Amazon CloudWatch Logs User Guide*. For a blog tutorial explaining how to monitor RDS logs, see [Build proactive database monitoring for Amazon RDS with Amazon CloudWatch Logs, AWS Lambda, and Amazon SNS](#).

Reading log file contents using REST

Amazon RDS provides a REST endpoint that allows access to DB instance log files. This is useful if you need to write an application to stream Amazon RDS log file contents.

The syntax is:

```
GET /v13/downloadCompleteLogFile/DBInstanceIdentifier/LogFileName HTTP/1.1
Content-type: application/json
host: rds.region.amazonaws.com
```

The following parameters are required:

- **DBInstanceIdentifier**—the name of the DB instance that contains the log file you want to download.
- **LogFileName**—the name of the log file to be downloaded.

The response contains the contents of the requested log file, as a stream.

The following example downloads the log file named *log/ERROR.6* for the DB instance named *sample-sql* in the *us-west-2* region.

```
GET /v13/downloadCompleteLogFile/sample-sql/log/ERROR.6 HTTP/1.1
host: rds.us-west-2.amazonaws.com
X-Amz-Security-Token: AQoDYXdzEIH///////////
wEa0AIXLhngC5zp9CyB1R6abwKrXHVR5efnAVN3XvR7IwqKYa1FSn6UyJuEFTft9n0bg1x4QJ+GXV9cpACkETq=
X-Amz-Date: 20140903T233749Z
X-Amz-Algorithm: AWS4-HMAC-SHA256
X-Amz-Credential: AKIADQKE4SARGYLE/20140903/us-west-2/rds/aws4_request
X-Amz-SignedHeaders: host
X-Amz-Content-SHA256: e3b0c44298fc1c229afbf4c8996fb92427ae41e4649b934de495991b7852b855
X-Amz-Expires: 86400
```

X-Amz-Signature: 353a4f14b3f250142d9afc34f9f9948154d46ce7d4ec091d0cdabbcf8b40c558

If you specify a nonexistent DB instance, the response consists of the following error:

- DBInstanceNotFound—*DB Instance Identifier* does not refer to an existing DB instance. (HTTP status code: 404)

MariaDB database log files

You can monitor the MariaDB error log, slow query log, and the general log. The MariaDB error log is generated by default; you can generate the slow query and general logs by setting parameters in your DB parameter group. Amazon RDS rotates all of the MariaDB log files; the intervals for each type are given following.

You can monitor the MariaDB logs directly through the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs. You can also access MariaDB logs by directing the logs to a database table in the main database and querying that table. You can use the mysqlbinlog utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see [Monitoring Amazon RDS log files \(p. 680\)](#).

Accessing MariaDB error logs

The MariaDB error log is written to the <host-name>.err file. You can view this file by using the Amazon RDS console, You can also retrieve the log using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs. The <host-name>.err file is flushed every 5 minutes, and its contents are appended to mysql-error-running.log. The mysql-error-running.log file is then rotated every hour and the hourly files generated during the last 24 hours are retained. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

MariaDB writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server did not encounter an error that resulted in a log entry.

Accessing the MariaDB slow query and general logs

You can write the MariaDB slow query log and general log to a file or database table by setting parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see [Working with parameter groups \(p. 289\)](#). You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, AWS CLI, or AWS SDKs.

You can control MariaDB logging by using the parameters in this list:

- `slow_query_log`: To create the slow query log, set to 1. The default is 0.
- `general_log`: To create the general log, set to 1. The default is 0.
- `long_query_time`: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query run time to be logged, in seconds. The default is 10 seconds; the

minimum is 0. If `log_output = FILE`, you can specify a floating point value that goes to microsecond resolution. If `log_output = TABLE`, you must specify an integer value with second resolution. Only queries whose run time exceeds the `long_query_time` value are logged. For example, setting `long_query_time` to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.

- `log_queries_not_using_indexes`: To log all queries that do not use an index to the slow query log, set this parameter to 1. The default is 0. Queries that do not use an index are logged even if their run time is less than the value of the `long_query_time` parameter.
- `log_output option`: You can specify one of the following options for the `log_output` parameter:
 - **TABLE** (default)– Write general queries to the `mysql.general_log` table, and slow queries to the `mysql.slow_log` table.
 - **FILE**– Write both general and slow query logs to the file system. Log files are rotated hourly.
 - **NONE**– Disable logging.

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. FILE and TABLE logging approach rotation and deletion as follows:

- When FILE logging is enabled, log files are examined every hour and log files older than 24 hours are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the largest log files are deleted until the log file size no longer exceeds the threshold.
- When TABLE logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space. It also occurs if the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of the allocated storage space. They're also rotated if the size of all logs combined is greater than 5 GB.

When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

You can rotate the `mysql.general_log` table by calling the `mysql.rds_rotate_general_log` procedure. You can rotate the `mysql.slow_log` table by calling the `mysql.rds_rotate_slow_log` procedure.

Table logs are rotated during a database version upgrade.

Amazon RDS records both TABLE and FILE log rotation in an Amazon RDS event and sends you a notification.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the `log_output` parameter to FILE. Like the MariaDB error log, these log files are rotated hourly. The log files that were generated during the previous 24 hours are retained.

For more information about the slow query and general logs, go to the following topics in the MariaDB documentation:

- [Slow query log](#)
- [General query log](#)

Publishing MariaDB logs to Amazon CloudWatch Logs

You can configure your MariaDB DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each MariaDB database log as a separate database stream in the log group. For example, suppose that you configure the export function to include the slow query log. Then slow query data is stored in a slow query log stream in the /aws/rds/instance/*my_instance*/slowquery log group.

The error log is enabled by default. The following table summarizes the requirements for the other MariaDB logs.

Log	Requirement
Audit log	The DB instance must use a custom option group with the MARIADB_AUDIT_PLUGIN option.
General log	The DB instance must use a custom parameter group with the parameter setting general_log = 1 to enable the general log.
Slow query log	The DB instance must use a custom parameter group with the parameter setting slow_query_log = 1 to enable the slow query log.
Log output	The DB instance must use a custom parameter group with the parameter setting log_output = FILE to write logs to the file system and publish them to CloudWatch Logs.

Console

To publish MariaDB logs to CloudWatch Logs from the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

You can publish a MariaDB logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

Note

A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish MariaDB logs by calling the following AWS CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the AWS CLI command you run.

Example

The following example modifies an existing MariaDB DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": \
    ["audit","error","general","slowquery"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": \
    ["audit","error","general","slowquery"]}'
```

Example

The following command creates a MariaDB DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '[{"audit","error","general","slowquery"}' \
```

```
--db-instance-class db.m4.large \
--engine mariadb
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier mydbinstance ^
--enable-cloudwatch-logs-exports '[{"audit","error","general","slowquery"}]' ^
--db-instance-class db.m4.large ^
--engine mariadb
```

RDS API

You can publish MariaDB logs with the RDS API. You can call the [ModifyDBInstance](#) operation with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

Note

A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish MariaDB logs by calling the following RDS API operations:

- [CreateDBInstance](#)
- [RestoreDBInstanceFromDBSnapshot](#)
- [RestoreDBInstanceFromS3](#)
- [RestoreDBInstanceToPointInTime](#)

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`
- `Engine`
- `DBInstanceClass`

Other parameters might be required depending on the AWS CLI command you run.

Log file size

The MariaDB slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour and log files older than 24 hours are removed. If the combined log file size exceeds the threshold after removing old log files, then the largest log files are deleted until the log file size no longer exceeds the threshold.

Managing table-based MariaDB logs

You can direct the general and slow query logs to tables on the DB instance. To do so, create a DB parameter group and set the `log_output` server parameter to TABLE. General queries are then logged

to the `mysql.general_log` table, and slow queries are logged to the `mysql.slow_log` table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. In order to enable logging to tables, you must also set the `general_log` and `slow_query_log` server parameters to 1.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to 0. A large amount of data often accumulates over time, which can use up a considerable percentage of your allocated storage space. Amazon RDS does not allow you to truncate the log tables, but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by PROMPT>:

```
PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;
```

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

Binary logging format

MariaDB on Amazon RDS supports the *row-based*, *statement-based*, and *mixed* binary logging formats. The default binary logging format is *mixed*. For details on the different MariaDB binary log formats, see [Binary log formats](#) in the MariaDB documentation.

If you plan to use replication, the binary logging format is important. This is because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see [Advantages and disadvantages of statement-based and row-based replication](#) in the MySQL documentation.

Important

Setting the binary logging format to row-based can result in very large binary log files. Large binary log files reduce the amount of storage available for a DB instance. They also can increase the amount of time to perform a restore operation of a DB instance.

Statement-based replication can cause inconsistencies between the source DB instance and a read replica. For more information, see [Unsafe statements for statement-based replication](#) in the MariaDB documentation.

To set the MariaDB binary logging format

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group that is used by the DB instance that you want to modify.

You can't modify a default parameter group. If the DB instance is using a default parameter group, create a new parameter group and associate it with the DB instance.

For more information on DB parameter groups, see [Working with parameter groups \(p. 289\)](#).

4. For **Parameter group actions**, choose **Edit**.
5. Set the `binlog_format` parameter to the binary logging format of your choice (**ROW**, **STATEMENT**, or **MIXED**).
6. Choose **Save changes** to save the updates to the DB parameter group.

Accessing MariaDB binary logs

You can use the `mysqlbinlog` utility to download binary logs in text format from MariaDB DB instances. The binary log is downloaded to your local computer. For more information about using the `mysqlbinlog` utility, go to [Using mysqlbinlog](#) in the MariaDB documentation.

To run the `mysqlbinlog` utility against an Amazon RDS instance, use the following options:

- Specify the `--read-from-remote-server` option.
- `--host`: Specify the DNS name from the endpoint of the instance.
- `--port`: Specify the port used by the instance.
- `--user`: Specify a MariaDB user that has been granted the replication slave permission.
- `--password`: Specify the password for the user, or omit a password value so the utility prompts you for a password.
- `--result-file`: Specify the local file that receives the output.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command `SHOW BINARY LOGS`.

For more information about `mysqlbinlog` options, go to [mysqlbinlog options](#) in the MariaDB documentation.

The following is an example:

For Linux, macOS, or Unix:

```
mysqlbinlog \
  --read-from-remote-server \
  --host=mariadbinstance1.1234abcd.region.rds.amazonaws.com \
  --port=3306 \
  --user ReplUser \
  --password <password> \
  --result-file=/tmp/binlog.txt
```

For Windows:

```
mysqlbinlog ^
  --read-from-remote-server ^
  --host=mariadbinstance1.1234abcd.region.rds.amazonaws.com ^
  --port=3306 ^
  --user ReplUser ^
  --password <password> ^
  --result-file=/tmp/binlog.txt
```

Amazon RDS normally purges a binary log as soon as possible. However, the binary log must still be available on the instance to be accessed by `mysqlbinlog`. To specify the number of hours for RDS to retain binary logs, use the `mysql.rds_set_configuration` stored procedure. Specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs don't take up too much storage.

The following example sets the retention period to 1 day.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the `mysql.rds_show_configuration` stored procedure.

```
call mysql.rds_show_configuration;
```

Binary log annotation

In a MariaDB DB instance, you can use the Annotate_rows event to annotate a row event with a copy of the SQL query that caused the row event. This approach provides similar functionality to enabling the binlog_rows_query_log_events parameter on an RDS for MySQL DB instance.

You can enable binary log annotations globally by creating a custom parameter group and setting the binlog_annotate_row_events parameter to 1. You can also enable annotations at the session level, by calling SET SESSION binlog_annotate_row_events = 1. Use the replicate_annotate_row_events to replicate binary log annotations to the replica instance if binary logging is enabled on it. No special privileges are required to use these settings.

The following is an example of a row-based transaction in MariaDB. The use of row-based logging is triggered by setting the transaction isolation level to read-committed.

```
CREATE DATABASE IF NOT EXISTS test;
USE test;
CREATE TABLE square(x INT PRIMARY KEY, y INT NOT NULL) ENGINE = InnoDB;
SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
BEGIN
INSERT INTO square(x, y) VALUES(5, 5 * 5);
COMMIT;
```

Without annotations, the binary log entries for the transaction look like the following:

```
BEGIN
/*!*/
# at 1163
# at 1209
#150922 7:55:57 server id 1855786460  end_log_pos 1209      Table_map: `test`.`square`
mapped to number 76
#150922 7:55:57 server id 1855786460  end_log_pos 1247      Write_rows: table id 76
flags: STMT_END_F
### INSERT INTO `test`.`square`
### SET
###   @1=5
###   @2=25
# at 1247
#150922 7:56:01 server id 1855786460  end_log_pos 1274      Xid = 62
COMMIT/*!*/;
```

The following statement enables session-level annotations for this same transaction, and disables them after committing the transaction:

```
CREATE DATABASE IF NOT EXISTS test;
USE test;
CREATE TABLE square(x INT PRIMARY KEY, y INT NOT NULL) ENGINE = InnoDB;
SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
SET SESSION binlog_annotate_row_events = 1;
BEGIN;
INSERT INTO square(x, y) VALUES(5, 5 * 5);
COMMIT;
SET SESSION binlog_annotate_row_events = 0;
```

With annotations, the binary log entries for the transaction look like the following:

```
BEGIN
```

```
/*!*/;
# at 423
# at 483
# at 529
#150922 8:04:24 server id 1855786460  end_log_pos 483  Annotate_rows:
#Q> INSERT INTO square(x, y) VALUES(5, 5 * 5)
#150922 8:04:24 server id 1855786460  end_log_pos 529  Table_map: `test`.`square` mapped
to number 76
#150922 8:04:24 server id 1855786460  end_log_pos 567  Write_rows: table id 76 flags:
STMT_END_F
### INSERT INTO `test`.`square`
### SET
###   @1=5
###   @2=25
# at 567
#150922 8:04:26 server id 1855786460  end_log_pos 594  Xid = 88
COMMIT/*!*/;
```

Microsoft SQL Server database log files

You can access Microsoft SQL Server error logs, agent logs, trace files, and dump files by using the Amazon RDS console, AWS CLI, or RDS API. For more information about viewing, downloading, and watching file-based database logs, see [Monitoring Amazon RDS log files \(p. 680\)](#).

Topics

- [Retention schedule \(p. 696\)](#)
- [Viewing the SQL Server error log by using the rds_read_error_log procedure \(p. 696\)](#)
- [Publishing SQL Server logs to Amazon CloudWatch Logs \(p. 696\)](#)

Retention schedule

Log files are rotated each day and whenever your DB instance is restarted. The following is the retention schedule for Microsoft SQL Server logs on Amazon RDS.

Log type	Retention schedule
Error logs	A maximum of 30 error logs are retained. Amazon RDS might delete error logs older than 7 days.
Agent logs	A maximum of 10 agent logs are retained. Amazon RDS might delete agent logs older than 7 days.
Trace files	Trace files are retained according to the trace file retention period of your DB instance. The default trace file retention period is 7 days. To modify the trace file retention period for your DB instance, see Setting the retention period for trace and dump files (p. 1309) .
Dump files	Dump files are retained according to the dump file retention period of your DB instance. The default dump file retention period is 7 days. To modify the dump file retention period for your DB instance, see Setting the retention period for trace and dump files (p. 1309) .

Viewing the SQL Server error log by using the rds_read_error_log procedure

You can use the Amazon RDS stored procedure `rds_read_error_log` to view error logs and agent logs. For more information, see [Viewing error and agent logs \(p. 1308\)](#).

Publishing SQL Server logs to Amazon CloudWatch Logs

With Amazon RDS for SQL Server, you can publish error and agent log events directly to Amazon CloudWatch Logs. Analyze the log data with CloudWatch Logs, then use CloudWatch to create alarms and view metrics.

With CloudWatch Logs, you can do the following:

- Store logs in highly durable storage space with a retention period that you define.
- Search and filter log data.
- Share log data between accounts.

- Export logs to Amazon S3.
- Stream data to Amazon OpenSearch Service.
- Process log data in real time with Amazon Kinesis Data Streams. For more information, see [Working with Amazon CloudWatch Logs](#) in the *Amazon Kinesis Data Analytics for SQL Applications Developer Guide*.

Amazon RDS publishes each SQL Server database log as a separate database stream in the log group. For example, if you publish error logs, error data is stored in an error log stream in the `/aws/rds/instance/my_instance/error` log group.

For Multi-AZ DB instances, Amazon RDS publishes the database log as two separate streams in the log group. For example, if you publish the error logs, the error data is stored in the error log streams `/aws/rds/instance/my_instance.node1/error` and `/aws/rds/instance/my_instance.node2/error` respectively. The log streams don't change during a failover and the error log stream of each node can contain error logs from primary or secondary instance.

Note

Publishing SQL Server logs to CloudWatch Logs isn't enabled by default. Publishing trace and dump files isn't supported. Publishing SQL Server logs to CloudWatch Logs is supported in all regions, except for Asia Pacific (Hong Kong).

Console

To publish SQL Server DB logs to CloudWatch Logs from the AWS Management Console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
You can choose **Agent log**, **Error log**, or both.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

To publish SQL Server logs, you can use the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

Note

A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish SQL Server logs using the following commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-to-point-in-time`

Example

The following example creates an SQL Server DB instance with CloudWatch Logs publishing enabled. The --enable-cloudwatch-logs-exports value is a JSON array of strings that can include error, agent, or both.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '[{"error", "agent"}]' \
    --db-instance-class db.m4.large \
    --engine sqlserver-se
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --enable-cloudwatch-logs-exports "[\"error\", \"agent\"]" ^
    --db-instance-class db.m4.large ^
    --engine sqlserver-se
```

Note

When using the Windows command prompt, you must escape double quotes ("") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing SQL Server DB instance to publish log files to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this object is EnableLogTypes, and its value is an array of strings that can include error, agent, or both.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["error", "agent"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration "{\"EnableLogTypes\": [\"error\", \"agent\"]}"
```

Note

When using the Windows command prompt, you must escape double quotes ("") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing SQL Server DB instance to disable publishing agent log files to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this object is DisableLogTypes, and its value is an array of strings that can include error, agent, or both.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
```

```
--db-instance-identifier mydbinstance \
--cloudwatch-logs-export-configuration '{"DisableLogTypes":["agent"]}'
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--cloudwatch-logs-export-configuration "{\"DisableLogTypes\": [\"agent\"]}"
```

Note

When using the Windows command prompt, you must escape double quotes ("") in JSON code by prefixing them with a backslash (\).

MySQL database log files

You can monitor the MySQL logs directly through the Amazon RDS console, Amazon RDS API, AWS CLI, or AWS SDKs. You can also access MySQL logs by directing the logs to a database table in the main database and querying that table. You can use the `mysqlbinlog` utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see [Monitoring Amazon RDS log files \(p. 680\)](#).

Topics

- [Overview of RDS for MySQL database logs \(p. 700\)](#)
- [Publishing MySQL logs to Amazon CloudWatch Logs \(p. 703\)](#)
- [Managing table-based MySQL logs \(p. 705\)](#)
- [Configuring MySQL binary logging \(p. 706\)](#)
- [Accessing MySQL binary logs \(p. 707\)](#)

Overview of RDS for MySQL database logs

You can monitor the following types of RDS for MySQL log files:

- Error log
- Slow query log
- General log
- Audit log

The RDS for MySQL error log is generated by default. You can generate the slow query and general logs by setting parameters in your DB parameter group.

Topics

- [RDS for MySQL error logs \(p. 700\)](#)
- [RDS for MySQL slow query and general logs \(p. 701\)](#)
- [MySQL audit log \(p. 701\)](#)
- [Log rotation and retention for RDS for MySQL \(p. 701\)](#)
- [Size limits on redo logs \(p. 702\)](#)
- [Size limits on BLOBs written to the redo log \(p. 702\)](#)

RDS for MySQL error logs

RDS for MySQL writes errors in the `mysql-error.log` file. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

RDS for MySQL writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server didn't encounter an error that would result in a log entry.

By design, the error logs are filtered so that only unexpected events such as errors are shown. However, the error logs also contain some additional database information, for example query progress, which isn't shown. Therefore, even without any actual errors the size of the error logs might increase because of ongoing database activities.

RDS for MySQL writes `mysql-error.log` to disk every 5 minutes. It appends the contents of the log to `mysql-error-running.log`.

RDS for MySQL rotates the `mysql-error-running.log` file every hour. It retains the logs generated during the last two weeks.

Note

The log retention period is different between Amazon RDS and Aurora.

RDS for MySQL slow query and general logs

You can write the RDS for MySQL slow query log and the general log to a file or a database table. To do so, set parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see [Working with parameter groups \(p. 289\)](#). You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs.

You can control RDS for MySQL logging by using the parameters in this list:

- `slow_query_log`: To create the slow query log, set to 1. The default is 0.
- `general_log`: To create the general log, set to 1. The default is 0.
- `long_query_time`: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query runtime to be logged, in seconds. The default is 10 seconds; the minimum is 0. If `log_output = FILE`, you can specify a floating point value that goes to microsecond resolution. If `log_output = TABLE`, you must specify an integer value with second resolution. Only queries whose runtime exceeds the `long_query_time` value are logged. For example, setting `long_query_time` to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.
- `log_queries_not_using_indexes`: To log all queries that do not use an index to the slow query log, set to 1. Queries that don't use an index are logged even if their runtime is less than the value of the `long_query_time` parameter. The default is 0.
- `log_output option`: You can specify one of the following options for the `log_output` parameter.
 - **TABLE** (default) – Write general queries to the `mysql.general_log` table, and slow queries to the `mysql.slow_log` table.
 - **FILE** – Write both general and slow query logs to the file system.
 - **NONE** – Disable logging.

For more information about the slow query and general logs, go to the following topics in the MySQL documentation:

- [The slow query log](#)
- [The general query log](#)

MySQL audit log

To access the audit log, the DB instance must use a custom option group with the `MARIADB_AUDIT_PLUGIN` option. For more information, see [MariaDB Audit Plugin support \(p. 1417\)](#).

Log rotation and retention for RDS for MySQL

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. RDS for MySQL handles rotation and deletion as follows:

- The MySQL slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour. MySQL removes log files more than two weeks old. If the combined log file size exceeds the threshold after removing old log files, then the oldest log files are deleted until the log file size no longer exceeds the threshold.
- When FILE logging is enabled, log files are examined every hour and log files more than two weeks old are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the oldest log files are deleted until the log file size no longer exceeds the threshold.
- When TABLE logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space. It also occurs if the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, then the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of the allocated storage space. They're also rotated if the size of all logs combined is greater than 5 GB. You can subscribe to the [low_free_storage](#) event to be notified when log tables are rotated to free up space. For more information, see [Working with Amazon RDS event notification \(p. 650\)](#).

When log tables are rotated, the current log table is first copied to a backup log table. Then the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

You can rotate the `mysql.general_log` table by calling the `mysql.rds_rotate_general_log` procedure. You can rotate the `mysql.slow_log` table by calling the `mysql.rds_rotate_slow_log` procedure.

Table logs are rotated during a database version upgrade.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the `log_output` parameter to `FILE`. Like the MySQL error log, these log files are rotated hourly. The log files that were generated during the previous two weeks are retained. Note that the retention period is different between Amazon RDS and Aurora.

Size limits on redo logs

For RDS for MySQL version 8.0.28 and lower, the `innodb_log_file_size` parameter determines the size of redo logs. The default value of this parameter is 256 MB. For information about limitations related to this limit, see [Size limits on BLOBs written to the redo log \(p. 702\)](#). For more information on how redo log size is calculated for these versions of MySQL, see `innodb_log_file_size` in the MySQL documentation.

For RDS for MySQL version 8.0.30 and higher, the `innodb_redo_log_capacity` parameter is used instead of the `innodb_log_file_size` parameter. The default value of the `innodb_redo_log_capacity` parameter is 2 GB. For more information, see [Changes in MySQL 8.0.30 in the MySQL documentation](#).

Size limits on BLOBs written to the redo log

For RDS for MySQL version 8.0.28 and lower, there is a size limit on BLOBs written to the redo log. To account for this limit, check the `innodb_log_file_size` parameter for your MySQL DB instance. Make sure that it is 10 times larger than the largest BLOB data size found in your tables plus the length of other variable length fields (VARCHAR, VARBINARY, TEXT) in these tables. For information about how to set parameter values, see [Working with parameter groups \(p. 289\)](#). For information about the redo log BLOB size limit, see [Changes in MySQL 5.6.20](#) in the MySQL documentation.

For RDS for MySQL version 8.0.30 and higher, the `innodb_redo_log_capacity` parameter is used instead of the `innodb_log_file_size` parameter. The size limit doesn't apply to the `innodb_redo_log_capacity` parameter. For more information, see [Size limits on redo logs \(p. 702\)](#).

Publishing MySQL logs to Amazon CloudWatch Logs

You can configure your MySQL DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each MySQL database log as a separate database stream in the log group. For example, if you configure the export function to include the slow query log, slow query data is stored in a slow query log stream in the `/aws/rds/instance/my_instance/slowquery` log group.

The error log is enabled by default. The following table summarizes the requirements for the other MySQL logs.

Log	Requirement
Audit log	The DB instance must use a custom option group with the <code>MARIADB_AUDIT_PLUGIN</code> option.
General log	The DB instance must use a custom parameter group with the parameter setting <code>general_log = 1</code> to enable the general log.
Slow query log	The DB instance must use a custom parameter group with the parameter setting <code>slow_query_log = 1</code> to enable the slow query log.
Log output	The DB instance must use a custom parameter group with the parameter setting <code>log_output = FILE</code> to write logs to the file system and publish them to CloudWatch Logs.

Console

To publish MySQL logs to CloudWatch Logs using the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

You can publish MySQL logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

Note

A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish MySQL logs by calling the following AWS CLI commands:

- [create-db-instance](#)
- [restore-db-instance-from-db-snapshot](#)
- [restore-db-instance-from-s3](#)
- [restore-db-instance-to-point-in-time](#)

Run one of these AWS CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the AWS CLI command you run.

Example

The following example modifies an existing MySQL DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": \
    ["audit","error","general","slowquery"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": \
    ["audit","error","general","slowquery"]}'
```

Example

The following example creates a MySQL DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '[{"audit","error","general","slowquery"}' \
```

```
--db-instance-class db.m4.large \
--engine MySQL
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier mydbinstance ^
--enable-cloudwatch-logs-exports '[{"audit","error","general","slowquery"}]' ^
--db-instance-class db.m4.large ^
--engine MySQL
```

RDS API

You can publish MySQL logs with the RDS API. You can call the [ModifyDBInstance](#) action with the following parameters:

- [DBInstanceIdentifier](#)
- [CloudwatchLogsExportConfiguration](#)

Note

A change to the [CloudwatchLogsExportConfiguration](#) parameter is always applied to the DB instance immediately. Therefore, the [ApplyImmediately](#) parameter has no effect.

You can also publish MySQL logs by calling the following RDS API operations:

- [CreateDBInstance](#)
- [RestoreDBInstanceFromDBSnapshot](#)
- [RestoreDBInstanceFromS3](#)
- [RestoreDBInstanceToPointInTime](#)

Run one of these RDS API operations with the following parameters:

- [DBInstanceIdentifier](#)
- [EnableCloudwatchLogsExports](#)
- [Engine](#)
- [DBInstanceClass](#)

Other parameters might be required depending on the AWS CLI command you run.

Managing table-based MySQL logs

You can direct the general and slow query logs to tables on the DB instance by creating a DB parameter group and setting the `log_output` server parameter to TABLE. General queries are then logged to the `mysql.general_log` table, and slow queries are logged to the `mysql.slow_log` table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. In order to enable logging to tables, you must also set the `general_log` and `slow_query_log` server parameters to 1.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to 0. A large amount of data often accumulates over time, which can use up a considerable

percentage of your allocated storage space. Amazon RDS doesn't allow you to truncate the log tables, but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by PROMPT>:

```
PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;
```

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

Configuring MySQL binary logging

The *binary log* is a set of log files that contain information about data modifications made to an MySQL server instance. The binary log contains information such as the following:

- Events that describe database changes such as table creation or row modifications
- Information about the duration of each statement that updated data
- Events for statements that could have updated data but didn't

The binary log records statements that are sent during replication. It is also required for some recovery operations. For more information, see [The Binary Log](#) and [Binary Log Overview](#) in the MySQL documentation.

The automated backups feature determines whether binary logging is turned on or off for MySQL. You have the following options:

Turn binary logging on

Set the backup retention period to a positive nonzero value.

Turn binary logging off

Set the backup retention period to zero.

For more information, see [Enabling automated backups \(p. 429\)](#).

MySQL on Amazon RDS supports the *row-based*, *statement-based*, and *mixed* binary logging formats. We recommend mixed unless you need a specific binlog format. For details on the different MySQL binary log formats, see [Binary logging formats](#) in the MySQL documentation.

If you plan to use replication, the binary logging format is important because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see [Advantages and disadvantages of statement-based and row-based replication](#) in the MySQL documentation.

Important

Setting the binary logging format to row-based can result in very large binary log files. Large binary log files reduce the amount of storage available for a DB instance and can increase the amount of time to perform a restore operation of a DB instance.

Statement-based replication can cause inconsistencies between the source DB instance and a read replica. For more information, see [Determination of safe and unsafe statements in binary logging](#) in the MySQL documentation.

To set the MySQL binary logging format

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group used by the DB instance you want to modify.

You can't modify a default parameter group. If the DB instance is using a default parameter group, create a new parameter group and associate it with the DB instance.

For more information on parameter groups, see [Working with parameter groups \(p. 289\)](#).

4. From **Parameter group actions**, choose **Edit**.
5. Set the `binlog_format` parameter to the binary logging format of your choice (**ROW**, **STATEMENT**, or **MIXED**). You can also use the value **OFF** to turn off binary logging.
6. Choose **Save changes** to save the updates to the DB parameter group.

After you perform these steps, you must reboot the DB instance for your changes to apply. For more information, see [Rebooting a DB instance \(p. 366\)](#).

Important

Changing a DB parameter group affects all DB instances that use that parameter group. If you want to specify different binary logging formats for different MySQL DB instances in an AWS Region, the DB instances must use different DB parameter groups. These parameter groups identify different logging formats. Assign the appropriate DB parameter group to the each DB instance.

Accessing MySQL binary logs

You can use the `mysqlbinlog` utility to download or stream binary logs from RDS for MySQL DB instances. The binary log is downloaded to your local computer, where you can perform actions such as replaying the log using the `mysql` utility. For more information about using the `mysqlbinlog` utility, go to [Using mysqlbinlog to back up binary log files](#).

To run the `mysqlbinlog` utility against an Amazon RDS instance, use the following options:

- Specify the `--read-from-remote-server` option.
- `--host`: Specify the DNS name from the endpoint of the instance.
- `--port`: Specify the port used by the instance.
- `--user`: Specify a MySQL user that has been granted the replication slave permission.
- `--password`: Specify the password for the user, or omit a password value so that the utility prompts you for a password.
- To have the file downloaded in binary format, specify the `--raw` option.
- `--result-file`: Specify the local file to receive the raw output.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command `SHOW BINARY LOGS`.
- To stream the binary log files, specify the `--stop-never` option.

For more information about `mysqlbinlog` options, go to [mysqlbinlog - utility for processing binary log files](#).

For example, see the following.

For Linux, macOS, or Unix:

```
mysqlbinlog \
  --read-from-remote-server \
  --host=MySQL56Instance1.cg034hpkmmt.region.rds.amazonaws.com \
  --port=3306 \
```

```
--user ReplUser \
--password \
--raw \
--result-file=/tmp/ \
binlog.00098
```

For Windows:

```
mysqlbinlog ^
--read-from-remote-server ^
--host=MySQL56Instance1.cg034hpkmmt.region.rds.amazonaws.com ^
--port=3306 ^
--user ReplUser ^
--password ^
--raw ^
--result-file=/tmp/ ^
binlog.00098
```

Amazon RDS normally purges a binary log as soon as possible, but the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs don't take up too much storage.

The following example sets the retention period to 1 day.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the `mysql.rds_show_configuration` stored procedure.

```
call mysql.rds_show_configuration;
```

Oracle database log files

You can access Oracle alert logs, audit files, and trace files by using the Amazon RDS console or API. For more information about viewing, downloading, and watching file-based database logs, see [Monitoring Amazon RDS log files \(p. 680\)](#).

The Oracle audit files provided are the standard Oracle auditing files. Amazon RDS supports the Oracle fine-grained auditing (FGA) feature. However, log access doesn't provide access to FGA events that are stored in the SYS.FGA_LOG\$ table and that are accessible through the DBA_FGA_AUDIT_TRAIL view.

The [DescribeDBLogFiles](#) API operation that lists the Oracle log files that are available for a DB instance ignores the MaxRecords parameter and returns up to 1,000 records. The call returns LastWritten as a POSIX date in milliseconds.

Topics

- [Retention schedule \(p. 709\)](#)
- [Working with Oracle trace files \(p. 709\)](#)
- [Publishing Oracle logs to Amazon CloudWatch Logs \(p. 712\)](#)
- [Previous methods for accessing alert logs and listener logs \(p. 715\)](#)

Retention schedule

The Oracle database engine might rotate log files if they get very large. To retain audit or trace files, download them. If you store the files locally, you reduce your Amazon RDS storage costs and make more space available for your data.

The following table shows the retention schedule for Oracle alert logs, audit files, and trace files on Amazon RDS.

Log type	Retention schedule
Alert logs	The text alert log is rotated daily with 30-day retention managed by Amazon RDS. The XML alert log is retained for at least seven days. You can access this log by using the ALERTLOG view.
Audit files	The default retention period for audit files is seven days. Amazon RDS might delete audit files older than seven days.
Trace files	The default retention period for trace files is seven days. Amazon RDS might delete trace files older than seven days.
Listener logs	The default retention period for the listener logs is seven days. Amazon RDS might delete listener logs older than seven days.

Note

Audit files and trace files share the same retention configuration.

Working with Oracle trace files

Following, you can find descriptions of Amazon RDS procedures to create, refresh, access, and delete trace files.

Topics

- [Listing files \(p. 710\)](#)
- [Generating trace files and tracing a session \(p. 710\)](#)
- [Retrieving trace files \(p. 711\)](#)
- [Purging trace files \(p. 711\)](#)

Listing files

You can use either of two procedures to allow access to any file in the background_dump_dest path. The first procedure refreshes a view containing a listing of all files currently in background_dump_dest.

```
EXEC rdsadmin.manage_tracefiles.refresh_tracefile_listing;
```

After the view is refreshed, query the following view to access the results.

```
SELECT * FROM rdsadmin.tracefile_listing;
```

An alternative to the previous process is to use FROM table to stream nonrelational data in a table-like format to list database directory contents.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('BDUMP'));
```

The following query shows the text of a log file.

```
SELECT text FROM
  TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP','alert_dbname.log.date'));
```

On a read replica, get the name of the BDUMP directory by querying V\$DATABASE.DB_UNIQUE_NAME. If the unique name is DATABASE_B, then the BDUMP directory is BDUMP_B. The following example queries the BDUMP name on a replica and then uses this name to query the contents of alert_DATABASE.log.2020-06-23.

```
SELECT 'BDUMP' || (SELECT regexp_replace(DB_UNIQUE_NAME,'.*(_[A-Z])', '\1') FROM V$DATABASE) AS BDUMP_VARIABLE FROM DUAL;
-----
BDUMP_VARIABLE
-----
BDUMP_B

SELECT TEXT FROM
  table(rdsadmin.rds_file_util.read_text_file('BDUMP_B','alert_DATABASE.log.2020-06-23'));
```

Generating trace files and tracing a session

Because there are no restrictions on ALTER SESSION, many standard methods to generate trace files in Oracle remain available to an Amazon RDS DB instance. The following procedures are provided for trace files that require greater access.

Oracle method	Amazon RDS method
oradebug hanganalyze 3	EXEC rdsadmin.manage_tracefiles.hanganalyze;

Oracle method	Amazon RDS method
oradebug dump systemstate 266	EXEC rdsadmin.manage_tracefiles.dump_systemstate;

You can use many standard methods to trace individual sessions connected to an Oracle DB instance in Amazon RDS. To enable tracing for a session, you can run subprograms in PL/SQL packages supplied by Oracle, such as DBMS_SESSION and DBMS_MONITOR. For more information, see [Enabling tracing for a session](#) in the Oracle documentation.

Retrieving trace files

You can retrieve any trace file in background_dump_dest using a standard SQL query on an Amazon RDS-managed external table. To use this method, you must execute the procedure to set the location for this table to the specific trace file.

For example, you can use the rdsadmin.tracefile_listing view mentioned preceding to list all of the trace files on the system. You can then set the tracefile_table view to point to the intended trace file using the following procedure.

```
EXEC
rdsadmin.manage_tracefiles.set_tracefile_table_location('CUST01_ora_3260_SYSTEMSTATE.trc');
```

The following example creates an external table in the current schema with the location set to the file provided. You can retrieve the contents into a local file using a SQL query.

```
SPPOOL /tmp/tracefile.txt
SELECT * FROM tracefile_table;
SPPOOL OFF;
```

Purging trace files

Trace files can accumulate and consume disk space. Amazon RDS purges trace files by default and log files that are older than seven days. You can view and set the trace file retention period using the show_configuration procedure. You should run the command SET SERVEROUTPUT ON so that you can view the configuration results.

The following example shows the current trace file retention period, and then sets a new trace file retention period.

```
# Show the current tracefile retention
SQL> EXEC rdsadmin.rdsadmin_util.show_configuration;
NAME:tracefile retention
VALUE:10080
DESCRIPTION:tracefile expiration specifies the duration in minutes before tracefiles in
bdbump are automatically deleted.

# Set the tracefile retention to 24 hours:
SQL> EXEC rdsadmin.rdsadmin_util.set_configuration('tracefile retention',1440);
SQL> commit;

#show the new tracefile retention
SQL> EXEC rdsadmin.rdsadmin_util.show_configuration;
NAME:tracefile retention
VALUE:1440
DESCRIPTION:tracefile expiration specifies the duration in minutes before tracefiles in
bdbump are automatically deleted.
```

In addition to the periodic purge process, you can manually remove files from the background_dump_dest. The following example shows how to purge all files older than five minutes.

```
EXEC rdsadmin.manage_tracefiles.purge_tracefiles(5);
```

You can also purge all files that match a specific pattern (if you do, don't include the file extension, such as .trc). The following example shows how to purge all files that start with SCHPOC1_ora_5935.

```
EXEC rdsadmin.manage_tracefiles.purge_tracefiles('SCHPOC1_ora_5935');
```

Publishing Oracle logs to Amazon CloudWatch Logs

You can configure your Amazon RDS for Oracle DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can analyze the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each Oracle database log as a separate database stream in the log group. For example, if you configure the export function to include the audit log, audit data is stored in an audit log stream in the /aws/rds/instance/my_instance/audit log group. RDS for Oracle supports the following logs:

- Alert log
- Trace log
- Audit log
- Listener log
- Oracle Management Agent log

This Oracle Management Agent log consists of the log groups shown in the following table.

Log name	CloudWatch log group
emctl.log	oemagent-emctl
emdctlj.log	oemagent-emdctlj
gcagent.log	oemagent-gcagent
gcagent_errors.log	oemagent-gcagent-errors
emagent.nohup	oemagent-emagent-nohup
secure.log	oemagent-secure

For more information, see [Locating Management Agent Log and Trace Files](#) in the Oracle documentation.

Console

To publish Oracle DB logs to CloudWatch Logs from the AWS Management Console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.

4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

To publish Oracle logs, you can use the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

Note

A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish Oracle logs using the following commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Example

The following example creates an Oracle DB instance with CloudWatch Logs publishing enabled. The `--cloudwatch-logs-export-configuration` value is a JSON array of strings. The strings can be any combination of alert, audit, listener, and trace.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration
    '['"trace","audit","alert","listener","oemagent"]' \
    --db-instance-class db.m5.large \
    --allocated-storage 20 \
    --engine oracle-ee \
    --engine-version 12.1.0.2.v18 \
    --license-model bring-your-own-license \
    --master-username myadmin \
    --master-user-password mypassword
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration trace alert audit listener oemagent ^
    --db-instance-class db.m5.large ^
    --allocated-storage 20 ^
    --engine oracle-ee ^
    --engine-version 12.1.0.2.v18 ^
    --license-model bring-your-own-license ^
    --master-username myadmin ^
    --master-user-password mypassword
```

Example

The following example modifies an existing Oracle DB instance to publish log files to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this object is EnableLogTypes, and its value is an array of strings with any combination of alert, audit, listener, and trace.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--cloudwatch-logs-export-configuration '{"EnableLogTypes": \
["trace", "alert", "audit", "listener", "oemagent"]}'
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--cloudwatch-logs-export-configuration EnableLogTypes="trace\", \"alert\", \"audit\",
\"listener\", \"oemagent\""
```

Example

The following example modifies an existing Oracle DB instance to disable publishing audit and listener log files to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this object is DisableLogTypes, and its value is an array of strings with any combination of alert, audit, listener, and trace.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--cloudwatch-logs-export-configuration '{"DisableLogTypes": ["audit", "listener"]}'
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--cloudwatch-logs-export-configuration DisableLogTypes="audit\", \"listener\""
```

RDS API

You can publish Oracle DB logs with the RDS API. You can call the [ModifyDBInstance](#) action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

Note

A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish Oracle logs by calling the following RDS API operations:

- [CreateDBInstance](#)
- [RestoreDBInstanceFromDBSnapshot](#)

- [RestoreDBInstanceFromS3](#)
- [RestoreDBInstanceToPointInTime](#)

Run one of these RDS API operations with the following parameters:

- DBInstanceIdentifier
- EnableCloudwatchLogsExports
- Engine
- DBInstanceClass

Other parameters might be required depending on the RDS operation that you run.

Previous methods for accessing alert logs and listener logs

You can view the alert log using the Amazon RDS console. You can also use the following SQL statement to access the alert log.

```
SELECT message_text FROM alertlog;
```

The listenerlog view contains entries for Oracle Database version 12.1.0.2 and earlier. To access the listener log for these database versions, use the following query.

```
SELECT message_text FROM listenerlog;
```

For Oracle Database versions 12.2.0.1 and later, access the listener log using Amazon CloudWatch Logs.

Note

Oracle rotates the alert and listener logs when they exceed 10 MB, at which point they are unavailable from Amazon RDS views.

RDS for PostgreSQL database log files

RDS for PostgreSQL logs database activities to the default PostgreSQL log file. For an on-premises PostgreSQL DB instance, these messages are stored locally in `log/postgresql.log`. For an RDS for PostgreSQL DB instance, the log file is available on the Amazon RDS instance. Also, you must use the Amazon RDS Console to view or download its contents. The default logging level captures login failures, fatal server errors, deadlocks, and query failures.

For more information about how you can view, download, and watch file-based database logs, see [Monitoring Amazon RDS log files \(p. 680\)](#). To learn more about PostgreSQL logs, see [Working with Amazon RDS and Aurora PostgreSQL logs: Part 1](#) and [Working with Amazon RDS and Aurora PostgreSQL logs: Part 2](#).

In addition to the standard PostgreSQL logs discussed in this topic, RDS for PostgreSQL also supports the PostgreSQL Audit extension (`pgAudit`). Most regulated industries and government agencies need to maintain an audit log or audit trail of changes made to data to comply with legal requirements. For information about installing and using `pgAudit`, see [Using pgAudit to log database activity \(p. 1951\)](#).

Topics

- [Parameters that affect logging behavior \(p. 716\)](#)
- [Turning on query logging for your RDS for PostgreSQL DB instance \(p. 718\)](#)
- [Publishing PostgreSQL logs to Amazon CloudWatch Logs \(p. 721\)](#)

Parameters that affect logging behavior

You can customize the logging behavior for your RDS for PostgreSQL DB instance by modifying various parameters. In the following table you can find the parameters that affect how long the logs are stored, when to rotate the log, and whether to output the log as a CSV (comma-separated value) format. You can also find the text output sent to `STDERR`, among other settings. To change settings for the parameters that are modifiable, use a custom DB parameter group for your RDS for PostgreSQL instance. For more information, see [Working with DB parameter groups \(p. 291\)](#). As noted in the table, the `log_line_prefix` can't be changed.

Parameter	Default	Description
<code>log_destination</code>	<code>stderr</code>	Sets the output format for the log. The default is <code>stderr</code> but you can also specify comma-separated value (CSV) by adding <code>csvlog</code> to the setting. For more information, see Setting the log destination (stderr, csvlog) (p. 718)
<code>log_filename</code>	<code>postgresql.log.%Y-%m-%d-%H</code>	Specifies the pattern for the log file name. In addition to the default, this parameter supports <code>postgresql.log.%Y-%m-%d</code> for the filename pattern.
<code>log_line_prefix</code>	<code>%t:%r:%u@%d:[%p]:</code>	Defines the prefix for each log line that gets written to <code>stderr</code> , to note the time (<code>%t</code>), remote host (<code>%r</code>), user (<code>%u</code>), database (<code>%d</code>), and process ID (<code>%p</code>). You can't modify this parameter.
<code>log_rotation_age</code>	60	Minutes after which log file is automatically rotated. You can change this value to between 1 and 1440 minutes. For more information, see Setting log file rotation (p. 717) .

Parameter	Default	Description
log_rotation_size	–	The size (kB) at which the log is automatically rotated. By default, this parameter isn't used because logs are rotated based on the log_rotation_age parameter. To learn more, see Setting log file rotation (p. 717) .
rds.log_retention_period	4320	PostgreSQL logs that are older than the specified number of minutes are deleted. The default value of 4320 minutes deletes log files after 3 days. For more information, see Setting the log retention period (p. 717) .

To identify application issues, you can look for query failures, login failures, deadlocks, and fatal server errors in the log. For example, suppose that you converted a legacy application from Oracle to Amazon RDS PostgreSQL, but not all queries converted correctly. These incorrectly formatted queries generate error messages that you can find in the logs to help identify problems. For more information about logging queries, see [Turning on query logging for your RDS for PostgreSQL DB instance \(p. 718\)](#).

In the following topics, you can find information about how to set various parameters that control the basic details for your PostgreSQL logs.

Topics

- [Setting the log retention period \(p. 717\)](#)
- [Setting log file rotation \(p. 717\)](#)
- [Setting the log destination \(stderr, csvlog\) \(p. 718\)](#)
- [Understanding the log_line_prefix parameter \(p. 718\)](#)

Setting the log retention period

The rds.log_retention_period parameter specifies how long your RDS for PostgreSQL DB instance keeps its log files. The default setting is 3 days (4,320 minutes), but you can set this value to anywhere from 1 day (1,440 minutes) to 7 days (10,080 minutes). Be sure that your RDS for PostgreSQL DB instance has sufficient storage to hold the log files for the period of time.

We recommend that you have your logs routinely published to Amazon CloudWatch Logs so that you can view and analyze system data long after the logs have been removed from your RDS for PostgreSQL DB instance. For more information, see [Publishing PostgreSQL logs to Amazon CloudWatch Logs \(p. 721\)](#).

Setting log file rotation

Amazon RDS creates new log files every hour by default. The timing is controlled by the log_rotation_age parameter. This parameter has a default value of 60 (minutes), but you can set it to anywhere from 1 minute to 24 hours (1,440 minutes). When it's time for rotation, a new distinct log file is created. The file is named according to the pattern specified by the log_filename parameter.

Log files can also be rotated according to their size, as specified in the log_rotation_size parameter. This parameter specifies that the log should be rotated when it reaches the specified size (in kilobytes). For an RDS for PostgreSQL DB instance, log_rotation_size is unset, that is, there is no value specified. However, you can set the parameter from 0-2097151 kB (kilobytes).

The log file names are based on the file name pattern specified in the log_filename parameter. The available settings for this parameter are as follows:

- `postgresql.log.%Y-%m-%d` – Default format for the log file name. Includes the year, month, and date in the name of the log file.
- `postgresql.log.%Y-%m-%d-%H` – Includes the hour in the log file name format.

For more information, see [log_rotation_age](#) and [log_rotation_size](#) in the PostgreSQL documentation.

Setting the log destination (`stderr`, `csvlog`)

By default, Amazon RDS PostgreSQL generates logs in standard error (`stderr`) format. This format is the default setting for the `log_destination` parameter. Each message is prefixed using the pattern specified in the `log_line_prefix` parameter. For more information, see [Understanding the log_line_prefix parameter \(p. 718\)](#).

RDS for PostgreSQL can also generate the logs in `csvlog` format. The `csvlog` is useful for analyzing the log data as comma-separated values (CSV) data. For example, suppose that you use the `log_fdw` extension to work with your logs as foreign tables. The foreign table created on `stderr` log files contains a single column with log event data. By adding `csvlog` to the `log_destination` parameter, you get the log file in the CSV format with demarcations for the multiple columns of the foreign table. You can now sort and analyze your logs more easily. To learn how to use the `log_fdw` with `csvlog`, see [Using the log_fdw extension to access the DB log using SQL \(p. 1987\)](#).

If you specify `csvlog` for this parameter, be aware that both `stderr` and `csvlog` files are generated. Be sure to monitor the storage consumed by the logs, taking into account the `rds.log_retention_period` and other settings that affect log storage and turnover. Using `stderr` and `csvlog` more than doubles the storage consumed by the logs.

If you add `csvlog` to `log_destination` and you want to revert to the `stderr` alone, you need to reset the parameter. To do so, open the Amazon RDS Console and then open the custom DB parameter group for your instance. Choose the `log_destination` parameter, choose **Edit parameter**, and then choose **Reset**.

For more information about configuring logging, see [Working with Amazon RDS and Aurora PostgreSQL logs: Part 1](#).

Understanding the `log_line_prefix` parameter

The `stderr` log format prefixes each log message with the details specified by the `log_line_prefix` parameter, as follows.

```
%t:%r:%u@d:[%p]:t
```

You can't change this setting. Each log entry sent to `stderr` includes the following information.

- `%t` – Time of log entry
- `%r` – Remote host address
- `%u@d` – User name @ database name
- `[%p]` – Process ID if available

Turning on query logging for your RDS for PostgreSQL DB instance

You can collect more detailed information about your database activities, including queries, queries waiting for locks, checkpoints, and many other details by setting some of the parameters listed in the following table. This topic focuses on logging queries.

Parameter	Default	Description
log_connections	–	Logs each successful connection.
log_disconnections	–	Logs the end of each session and its duration.
log_checkpoints	1	Logs each checkpoint.
log_lock_waits	–	Logs long lock waits. By default, this parameter isn't set.
log_min_duration_sample	–	(ms) Sets the minimum execution time above which a sample of statements is logged. Sample size is set using the log_statement_sample_rate parameter.
log_min_duration_statement	all	Sets the type of statements logged.
log_statement	–	Sets the type of statements logged. By default, this parameter isn't set, but you can change it to all, ddl, or mod to specify the types of SQL statements that you want logged. If you specify anything other than none for this parameter, you should also take additional steps to prevent the exposure of passwords in the log files. For more information, see Mitigating risk of password exposure when using query logging (p. 721) .
log_statement_sample_rate		The percentage of statements exceeding the time specified in log_min_duration_sample to be logged, expressed as a floating point value between 0.0 and 1.0.
log_statement_stats	–	Writes cumulative performance statistics to the server log.

Using logging to find slow performing queries

You can log SQL statements and queries to help find slow performing queries. You turn on this capability by modifying the settings in the log_statement and log_min_duration parameters as outlined in this section. Before turning on query logging for your RDS for PostgreSQL DB instance, you should be aware of possible password exposure in the logs and how to mitigate the risks. For more information, see [Mitigating risk of password exposure when using query logging \(p. 721\)](#).

Following, you can find reference information about the log_statement and log_min_duration parameters.

log_statement

This parameter specifies the type of SQL statements that should get sent to the log. The default value is none. If you change this parameter to all, ddl, or mod, be sure to apply recommended actions to mitigate the risk of exposing passwords in the logs. For more information, see [Mitigating risk of password exposure when using query logging \(p. 721\)](#).

all

Logs all statements. This setting is recommended for debugging purposes.

ddl

Logs all data definition language (DDL) statements, such as CREATE, ALTER, DROP, and so on.

mod

Logs all DDL statements and data manipulation language (DML) statements, such as INSERT, UPDATE, and DELETE, which modify the data.

none

No SQL statements get logged. We recommend this setting to avoid the risk of exposing passwords in the logs.

log_min_duration_statement

Any SQL statement that runs longer than the number of milliseconds specified by this parameter setting gets logged. By default, this parameter isn't set. Turning on this parameter can help you find unoptimized queries.

-1-2147483647

The number of milliseconds (ms) of runtime over which a statement gets logged.

To set up query logging

These steps assume that your RDS for PostgreSQL DB instance uses a custom DB parameter group.

1. Set the `log_statement` parameter to `all`. The following example shows the information that is written to the `postgresql.log` file with this parameter setting.

```
2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:LOG: statement: SELECT
  feedback, s.sentiment,s.confidence
FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;
2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:LOG: QUERY STATISTICS
2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:DETAIL: ! system usage
  stats:
! 0.017355 s user, 0.000000 s system, 0.168593 s elapsed
! [0.025146 s user, 0.000000 s system total]
! 36644 kB max resident size
! 0/8 [0/8] filesystem blocks in/out
! 0/733 [0/1364] page faults/reclaims, 0 [0] swaps
! 0 [0] signals rcvd, 0/0 [0/0] messages rcvd/sent
! 19/0 [27/0] voluntary/involuntary context switches
2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:STATEMENT: SELECT
  feedback, s.sentiment,s.confidence
FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;
2022-10-05 22:05:56 UTC:52.95.4.1(11335):postgres@labdb:[3639]:ERROR: syntax error at
  or near "ORDER" at character 1
2022-10-05 22:05:56 UTC:52.95.4.1(11335):postgres@labdb:[3639]:STATEMENT: ORDER BY
  s.confidence DESC;
----- END OF LOG -----
```

2. Set the `log_min_duration_statement` parameter. The following example shows the information that is written to the `postgresql.log` file when the parameter is set to 1.

Queries that exceed the duration specified in the `log_min_duration_statement` parameter are logged. The following shows an example. You can view the log file for your RDS for PostgreSQL DB instance in the Amazon RDS Console.

```
2022-10-05 19:05:19 UTC:52.95.4.1(6461):postgres@labdb:[6144]:LOG: statement: DROP
table comments;
2022-10-05 19:05:19 UTC:52.95.4.1(6461):postgres@labdb:[6144]:LOG: duration: 167.754 ms
2022-10-05 19:08:07 UTC:@:[355]:LOG: checkpoint starting: time
2022-10-05 19:08:08 UTC:@:[355]:LOG: checkpoint complete: wrote 11 buffers (0.0%); 0
WAL file(s) added, 0 removed, 0 recycled; write=1.013 s, sync=0.006 s, total=1.033 s;
sync files=8, longest=0.004 s, average=0.001 s; distance=131028 kB, estimate=131028 kB
----- END OF LOG -----
```

Mitigating risk of password exposure when using query logging

We recommend that you keep `log_statement` set to none to avoid exposing passwords. If you set `log_statement` to all, ddl, or mod, we recommend that you take one or more of the following steps.

- For the client, encrypt sensitive information. For more information, see [Encryption Options](#) in the PostgreSQL documentation. Use the ENCRYPTED (and UNENCRYPTED) options of the CREATE and ALTER statements. For more information, see [CREATE USER](#) in the PostgreSQL documentation.
- For your RDS for PostgreSQL DB instance, set up and use the PostgreSQL Auditing (pgAudit) extension. This extension redacts sensitive information in CREATE and ALTER statements sent to the log. For more information, see [Using pgAudit to log database activity \(p. 1951\)](#).
- Restrict access to the CloudWatch logs.
- Use stronger authentication mechanisms such as IAM.

Publishing PostgreSQL logs to Amazon CloudWatch Logs

To store your PostgreSQL log records in highly durable storage, you can use Amazon CloudWatch Logs. With CloudWatch Logs, you can also perform real-time analysis of log data and use CloudWatch to view metrics and create alarms. For example, if you set `log_statements` to ddl, you can set up an alarm to alert you whenever a DDL statement is executed. You can choose to have your PostgreSQL logs uploaded to CloudWatch Logs during the process of creating your RDS for PostgreSQL DB instance. If you chose not to upload logs at that time, you can later modify your instance to start uploading logs from that point forward. In other words, existing logs aren't uploaded. Only new logs are uploaded as they're created on your modified RDS for PostgreSQL DB instance. When PostgreSQL logs are uploaded to CloudWatch Logs, they're no longer kept in the **Logs** section of the **Logs & events** tab. Instead, to view them you CloudWatch to view your logs.

All currently available RDS for PostgreSQL versions support publishing log files to CloudWatch Logs. For more information, see [Amazon RDS for PostgreSQL updates](#) in the *Amazon RDS for PostgreSQL Release Notes*.

To work with CloudWatch Logs, configure your RDS for PostgreSQL DB instance to publish log data to a log group.

You can publish the following log types to CloudWatch Logs for RDS for PostgreSQL:

- Postgresql log
- Upgrade log

After you complete the configuration, Amazon RDS publishes the log events to log streams within a CloudWatch log group. For example, the PostgreSQL log data is stored within the log group `/aws/rds/instance/my_instance/postgresql`. To view your logs, open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.

Console

To publish PostgreSQL logs to CloudWatch Logs using the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify, and then choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.

The **Log exports** section is available only for PostgreSQL versions that support publishing to CloudWatch Logs.

5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

You can publish PostgreSQL logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters.

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

Note

A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish PostgreSQL logs by calling the following CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-to-point-in-time`

Run one of these CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the CLI command you run.

Example Modify an instance to publish logs to CloudWatch Logs

The following example modifies an existing PostgreSQL DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `postgresql` and `upgrade`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["postgresql", "upgrade"]}'
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--cloudwatch-logs-export-configuration '{"EnableLogTypes": ["postgresql", "upgrade"]}'
```

Example Create an instance to publish logs to CloudWatch Logs

The following example creates a PostgreSQL DB instance and publishes log files to CloudWatch Logs. The --enable-cloudwatch-logs-exports value is a JSON array of strings. The strings can be any combination of postgresql and upgrade.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier mydbinstance \
--enable-cloudwatch-logs-exports '['"postgresql", "upgrade"]' \
--db-instance-class db.m4.large \
--engine postgres
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier mydbinstance ^
--enable-cloudwatch-logs-exports '['"postgresql", "upgrade"]' ^
--db-instance-class db.m4.large ^
--engine postgres
```

RDS API

You can publish PostgreSQL logs with the RDS API. You can call the [ModifyDBInstance](#) action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

Note

A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish PostgreSQL logs by calling the following RDS API operations:

- [CreateDBInstance](#)
- [RestoreDBInstanceFromDBSnapshot](#)
- [RestoreDBInstanceToPointInTime](#)

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`

- Engine
- DBInstanceClass

Other parameters might be required depending on the operation that you run.

Monitoring Amazon RDS API calls in AWS CloudTrail

AWS CloudTrail is an AWS service that helps you audit your AWS account. AWS CloudTrail is turned on for your AWS account when you create it. For more information about CloudTrail, see the [AWS CloudTrail User Guide](#).

Topics

- [CloudTrail integration with Amazon RDS \(p. 725\)](#)
- [Amazon RDS log file entries \(p. 725\)](#)

CloudTrail integration with Amazon RDS

All Amazon RDS actions are logged by CloudTrail. CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS.

CloudTrail events

CloudTrail captures API calls for Amazon RDS as events. An *event* represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. Events include calls from the Amazon RDS console and from code calls to the Amazon RDS API operations.

Amazon RDS activity is recorded in a CloudTrail event in [Event history](#). You can use the CloudTrail console to view the last 90 days of recorded API activity and events in an AWS Region. For more information, see [Viewing events with CloudTrail event history](#).

CloudTrail trails

For an ongoing record of events in your AWS account, including events for Amazon RDS, create a *trail*. A trail is a configuration that enables delivery of events to a specified Amazon S3 bucket. CloudTrail typically delivers log files within 15 minutes of account activity.

Note

If you don't configure a trail, you can still view the most recent events in the CloudTrail console in [Event history](#).

You can create two types of trails for an AWS account: a trail that applies to all Regions, or a trail that applies to one Region. By default, when you create a trail in the console, the trail applies to all Regions.

Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- [Overview for creating a trail](#)
- [CloudTrail supported services and integrations](#)
- [Configuring Amazon SNS notifications for CloudTrail](#)
- [Receiving CloudTrail log files from multiple Regions](#) and [Receiving CloudTrail log files from multiple accounts](#)

Amazon RDS log file entries

CloudTrail log files contain one or more log entries. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `CreateDBInstance` action.

```
{
    "eventVersion": "1.04",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AKIAIOSFODNN7EXAMPLE",

"dbiResourceId": "db-ETDZIIXHEWY5N7GXVC4SH7H5IA",
"dBSecurityGroups": [],
"pendingModifiedValues": [
    "masterUserPassword": "*****",
    "pendingCloudwatchLogsExports": {
        "logTypesToEnable": [
            "audit",
            "error",
            "general",
            "slowquery"
        ]
    }
],
"dBInstanceStatus": "creating",
"publiclyAccessible": true,
"domainMemberships": [],
"copyTagsToSnapshot": false,
"dBInstanceIdentifier": "test-instance",
"licenseModel": "general-public-license",
"iAMDatabaseAuthenticationEnabled": false,
"performanceInsightsEnabled": false,
"vpcSecurityGroups": [
    {
        "status": "active",
        "vpcSecurityGroupId": "sg-f839b688"
    }
],
"requestID": "daf2e3f5-96a3-4df7-a026-863f96db793e",
"eventID": "797163d3-5726-441d-80a7-6eeb7464acd4",

```

```
    "eventType": "AwsApiCall",
    "recipientAccountId": "123456789012"
}
```

As shown in the `userIdentity` element in the preceding example, every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information about the `userIdentity`, see the [CloudTrail userIdentity element](#). For more information about `CreateDBInstance` and other Amazon RDS actions, see the [Amazon RDS API Reference](#).

Monitoring Amazon RDS for Oracle with Database Activity Streams

By using Database Activity Streams, you can monitor near-real-time streams of database activity.

Topics

- [Overview of Database Activity Streams \(p. 729\)](#)
- [Configuring unified auditing for Oracle Database \(p. 732\)](#)
- [Starting a database activity stream \(p. 732\)](#)

- [Getting the status of a database activity stream \(p. 736\)](#)
- [Stopping a database activity stream \(p. 737\)](#)
- [Monitoring database activity streams \(p. 738\)](#)
- [Managing access to database activity streams \(p. 752\)](#)

Overview of Database Activity Streams

As an RDS for Oracle database administrator, you need to safeguard your database and meet compliance and regulatory requirements. One strategy is to integrate database activity streams with your monitoring tools. In this way, you monitor and set alarms for auditing activity in your Oracle database.

Security threats are both external and internal. To protect against internal threats, you can control administrator access to data streams by configuring the Database Activity Streams feature. RDS for Oracle DBAs don't have access to the collection, transmission, storage, and processing of the streams.

Topics

- [How database activity streams work \(p. 729\)](#)
- [Unified auditing in Oracle Database \(p. 730\)](#)
- [Asynchronous mode for database activity streams \(p. 731\)](#)

- [Region and version availability \(p. 731\)](#)
- [Supported DB instance classes for database activity streams \(p. 731\)](#)

How database activity streams work

Amazon RDS for Oracle pushes activities to an Amazon Kinesis data stream in near real time. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Kinesis Data Firehose and AWS Lambda to consume the stream and store the data.

Important

Use of the Database Activity Streams feature in Amazon RDS for Oracle is free, but Amazon Kinesis charges for a data stream. For more information, see [Amazon Kinesis Data Streams pricing](#).

You can configure applications for compliance management to consume database activity streams. These applications can use the stream to generate alerts and audit activity on your Oracle database.
[Database Activity Streams](#)

RDS for Oracle supports database activity streams in Multi-AZ deployments. In this case, database activity streams audit both the primary and standby instances.

Unified auditing in Oracle Database

RDS for Oracle doesn't capture database activity by default. You create and manage audit policies in Oracle Database yourself.

Auditing is the monitoring and recording of configured database actions. In an Oracle database, a *unified audit policy* is a named group of audit settings that you can use to audit an aspect of user behavior. A policy can be as simple as auditing the activities of a single user. You can also create complex audit policies that use conditions.

An Oracle database writes audit records, including SYS audit records, to the *unified audit trail*. For example, if an error occurs during an INSERT statement, standard auditing indicates the error number and the SQL that was executed. The audit trail resides in a read-only table in the AUDSYS schema. To access these records, query the UNIFIED_AUDIT_TRAIL data dictionary view.

Typically, you configure database activity streams as follows:

1. Create an Oracle Database audit policy by using the CREATE AUDIT POLICY command.

The Oracle Database generates audit records.

2. Enable the audit policy by using the AUDIT POLICY command.

3. Configure database activity streams.

Only activities that match the Oracle Database audit policies are captured and sent to the Amazon Kinesis data stream. When database activity streams are enabled, an Oracle database administrator can't alter the audit policy or remove audit logs.

To learn more about unified audit policies, see [About Auditing Activities with Unified Audit Policies and AUDIT](#) in the *Oracle Database Security Guide*.

Topics

- [Non-native audit fields \(p. 730\)](#)
- [DB parameter group override \(p. 730\)](#)

Non-native audit fields

When you start a database activity stream, every database event generates a corresponding activity stream event. For example, a database user might run SELECT and INSERT statements. The database audits these events and sends them to an Amazon Kinesis data stream.

The events are represented in the stream as JSON objects. A JSON object contains a DatabaseActivityMonitoringRecord, which contains a databaseActivityEventList array. Predefined fields in the array include class, clientApplication, and command.

Most events in the unified audit trail for Oracle Database map to fields in the RDS data activity stream. For example, the UNIFIED_AUDIT_TRAIL.SQL_TEXT field in unified auditing maps to the commandText field in a database activity stream. However, Oracle Database audit fields such as OS_USERNAME don't map to predefined fields in a database activity stream.

By default, an activity stream doesn't include engine-native audit fields. You can configure RDS for Oracle so that it includes these extra fields in the engineNativeAuditFields JSON object.

DB parameter group override

Typically, you turn on unified auditing in RDS for Oracle by attaching a parameter group. However, Database Activity Streams would require additional configuration. To improve your customer experience, Amazon RDS does the following:

- If you enable an activity stream, RDS for Oracle ignores the auditing parameters in the parameter group.
- If you disable an activity stream, RDS for Oracle stops ignoring the auditing parameters.

Asynchronous mode for database activity streams

Activity streams in RDS for Oracle are always asynchronous. When a database session generates an activity stream event, the session returns to normal activities immediately. In the background, RDS for Oracle makes the activity stream event into a durable record.

If an error occurs in the background task, Amazon RDS generates an event. This event indicates the beginning and end of any time windows where activity stream event records might have been lost. Asynchronous mode favors database performance over the accuracy of the activity stream.

Requirements for database activity streams

In RDS for Oracle, database activity streams have the following requirements and limitations:

- Amazon Kinesis is required for database activity streams.
- AWS Key Management Service (AWS KMS) is required for database activity streams because they are always encrypted.
- Applying additional encryption to your Amazon Kinesis data stream is incompatible with database activity streams, which are already encrypted with your AWS KMS key.
- You create and manage audit policies yourself. Unlike Amazon Aurora, RDS for Oracle doesn't capture database activities by default.
- In a Multi-AZ deployment, start the database activity stream on only the primary DB instance. The activity stream audits both the primary and standby DB instances automatically. No additional steps are required during a failover.
- CDBs aren't supported.
- Oracle read replicas aren't supported.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with database activity streams, see [Database activity streams \(p. 85\)](#).

Supported DB instance classes for database activity streams

You can use database activity streams with the following DB instance classes:

- db.m4
- db.m5.*
- db.r4
- db.r5.*
- db.z1d

Note

The memory optimized db.r5 classes, which use the naming pattern db.r5.*instance_size*.tpcthreads_per_core.memratio, aren't supported.

For more information about instance class types, see [DB instance classes \(p. 10\)](#).

Configuring unified auditing for Oracle Database

When you configure unified auditing for use with database activity streams, the following situations are possible:

- Unified auditing isn't configured for your Oracle database.

In this case, create new policies with the CREATE AUDIT POLICY command, and then enable them with the AUDIT POLICY command. The following example creates and enables a policy to monitor users with specific privileges and roles.

```
CREATE AUDIT POLICY table_pol
PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
ROLES emp_admin, sales_admin;

AUDIT POLICY table_pol;
```

For complete instructions, see [Configuring Audit Policies](#) in the Oracle Database documentation.

- Unified auditing is configured for your Oracle database.

When you enable a database activity stream, RDS for Oracle automatically clears existing audit data. It also revokes audit trail privileges. RDS for Oracle can no longer do the following:

- Purge unified audit trail records.
- Add, delete, or modify the unified audit policy.
- Update the last archived time stamp.

Important

We strongly recommend that you back up your audit data before enabling a database activity stream.

For a description of the UNIFIED_AUDIT_TRAIL view, see [UNIFIED_AUDIT_TRAIL](#). If you have an account with Oracle Support, see [How To Purge The UNIFIED AUDIT TRAIL](#).

Starting a database activity stream

When you start an activity stream for an Oracle DB instance, each database activity event, such as a change or access, generates an activity stream event. SQL commands such as CONNECT and SELECT generate access events. SQL commands such as CREATE and INSERT generate change events.

Important

Turning on an activity stream for an Oracle DB instance clears existing audit data. It also revokes audit trail privileges. When the stream is enabled, RDS for Oracle can no longer do the following:

- Purge unified audit trail records.
- Add, delete, or modify the unified audit policy.
- Update the last archived time stamp.

Console

To start a database activity stream

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

3. Choose the RDS for Oracle instance on which you want to start an activity stream. In a Multi-AZ deployment, start the stream on only the primary instance. The activity stream audits both the primary and the standby instances.
4. For **Actions**, choose **Start activity stream**.

The **Start database activity stream: *name*** window appears, where *name* is your RDS instance.

5. Enter the following settings:

- For **AWS KMS key**, choose a key from the list of AWS KMS keys.

RDS for Oracle uses the KMS key to encrypt the key that in turn encrypts database activity. Choose a KMS key other than the default key. For more information about encryption keys and AWS KMS, see [What is AWS Key Management Service?](#) in the *AWS Key Management Service Developer Guide*.

- For **Database activity events**, choose **Include Oracle native audit fields** to include Oracle-specific audit fields in the stream.
- Choose **Immediately**.

When you choose **Immediately**, the RDS instance restarts right away. If you choose **During the next maintenance window**, the RDS instance doesn't restart right away. In this case, the database activity stream doesn't start until the next maintenance window.

6. Choose **Start database activity stream**.

The status for the Oracle database shows that the activity stream is starting.

Note

If you get the error You can't start a database activity stream in this configuration, check [Supported DB instance classes for database activity streams \(p. 731\)](#) to see whether your RDS instance is using a supported instance class.

AWS CLI

To start database activity streams for an Oracle DB instance, configure the database using the [start-activity-stream](#) AWS CLI command.

- **--resource-arn *arn*** – Specifies the Amazon Resource Name (ARN) of the DB instance.
- **--kms-key-id *key*** – Specifies the KMS key identifier for encrypting messages in the database activity stream. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the AWS KMS key.
- **--engine-native-audit-fields-included** – Includes engine-specific unified auditing fields in the data stream. To exclude these fields, specify **--no-engine-native-audit-fields-included** (default).

The following example starts a database activity stream for an Oracle DB instance in asynchronous mode.

For Linux, macOS, or Unix:

```
aws rds start-activity-stream \
--mode async \
--kms-key-id my-kms-key-arn \
--resource-arn my-instance-arn \
--engine-native-audit-fields-included \
--apply-immediately
```

For Windows:

```
aws rds start-activity-stream ^
--mode async ^
--kms-key-id my-kms-key-arn ^
--resource-arn my-instance-arn ^
--engine-native-audit-fields-included ^
--apply-immediately
```

RDS API

To start database activity streams for an Oracle DB instance, configure the instance using the [StartActivityStream](#) operation.

Call the action with the parameters below:

- Region
- KmsKeyId
- ResourceArn
- Mode
- EngineNativeAuditFieldsIncluded

Modifying a database activity stream

You might want to customize your RDS for Oracle audit policy when your activity stream is started. If you don't want to lose time and data by stopping your activity stream, you can change the *audit policy state* to either of the following settings:

Locked (default)

The audit policies in your database are read-only.

Unlocked

The audit policies in your database are read/write.

The basic steps are as follows:

1. Modify the audit policy state to unlocked.
2. Customize your audit policy.
3. Modify the audit policy state to locked.

Console

To modify the audit policy state of your activity stream

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. For **Actions**, choose **Modify database activity stream**.

The **Modify database activity stream: name** window appears, where *name* is your RDS instance.

4. Choose either of the following options:

Locked

When you lock your audit policy, it becomes read-only. You can't edit your audit policy unless you unlock the policy or stop the activity stream.

Unlocked

When you unlock your audit policy, it becomes read/write. You can edit your audit policy while the activity stream is started.

5. Choose **Modify DB activity stream**.

The status for the Oracle database shows **Configuring activity stream**.

6. (Optional) Choose the DB instance link. Then choose the **Configuration** tab.

The **Audit policy status** field shows one of the following values:

- **Locked**
- **Unlocked**
- **Locking policy**
- **Unlocking policy**

AWS CLI

To modify the activity stream state for an Oracle DB instance, use the [modify-activity-stream](#) AWS CLI command.

Option	Required?	Description
--resource-arn <i>my-instance-ARN</i>	Yes	The Amazon Resource Name (ARN) of your RDS for Oracle DB instance.
--audit-policy-state	No	The new state of the audit policy for the database activity stream on your instance: locked or unlocked.

The following example unlocks the audit policy for the activity stream started on *my-instance-ARN*.

For Linux, macOS, or Unix:

```
aws rds modify-activity-stream \
--resource-arn my-instance-ARN \
--audit-policy-state unlocked
```

For Windows:

```
aws rds modify-activity-stream ^
--resource-arn my-instance-ARN ^
--audit-policy-state unlocked
```

The following example describes the instance *my-instance*. The partial sample output shows that the audit policy is unlocked.

```
aws rds describe-db-instances --db-instance-identifier my-instance

{
    "DBInstances": [
        {
            ...
            "Engine": "oracle-ee",
            ...
            "ActivityStreamStatus": "started",
```

```
    "ActivityStreamKmsKeyId": "ab12345e-1111-2bc3-12a3-ab1cd12345e",
    "ActivityStreamKinesisStreamName": "aws-rds-das-db-AB1CDEFG23GHIJK4LMNOPQRST",
    "ActivityStreamMode": "async",
    "ActivityStreamEngineNativeAuditFieldsIncluded": true,
    "ActivityStreamPolicyStatus": "unlocked",
    ...
]
}
```

RDS API

To modify the policy state of your database activity stream, use the [ModifyActivityStream](#) operation.

Call the action with the parameters below:

- `AuditPolicyState`
- `ResourceArn`

Getting the status of a database activity stream

You can get the status of an activity stream for your RDS for Oracle DB instance using the console or AWS CLI.

Console

To get the status of a database activity stream

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance link.
3. Choose the **Configuration** tab, and check **Database activity stream** for status.

AWS CLI

You can get the activity stream configuration for a database as the response to a [describe-db-instances](#) CLI request.

The following example describes *my-instance*.

```
aws rds --region my-region describe-db-instances --db-instance-identifier my-db
```

The following example shows a JSON response. The following fields are shown:

- `ActivityStreamKinesisStreamName`
- `ActivityStreamKmsKeyId`
- `ActivityStreamStatus`
- `ActivityStreamMode`
- `ActivityStreamPolicyStatus`

```
{
  "DBInstances": [
    {
      ...
      "Engine": "oracle-ee",
    }
  ]
}
```

```
    ...
    "ActivityStreamStatus": "starting",
    "ActivityStreamKmsKeyId": "ab12345e-1111-2bc3-12a3-ab1cd12345e",
    "ActivityStreamKinesisStreamName": "aws-rds-das-db-AB1CDEFG23GHIJK4LMNOPQRST",
    "ActivityStreamMode": "async",
    "ActivityStreamEngineNativeAuditFieldsIncluded": true,
    "ActivityStreamPolicyStatus": "locked",
    ...
}
]
```

RDS API

You can get the activity stream configuration for a database as the response to a [DescribeDBInstances](#) operation.

Stopping a database activity stream

You can stop an activity stream using the console or AWS CLI.

If you delete your RDS for Oracle DB instance, the activity stream is stopped and the underlying Amazon Kinesis stream is deleted automatically.

Console

To turn off an activity stream

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose a database that you want to stop the database activity stream for.
4. For **Actions**, choose **Stop activity stream**. The **Database Activity Stream** window appears.
 - a. Choose **Immediately**.

When you choose **Immediately**, the RDS instance restarts right away. If you choose **During the next maintenance window**, the RDS instance doesn't restart right away. In this case, the database activity stream doesn't stop until the next maintenance window.

- b. Choose **Continue**.

AWS CLI

To stop database activity streams for your database, configure the DB instance using the AWS CLI command [stop-activity-stream](#). Identify the AWS Region for the DB instance using the `--region` parameter. The `--apply-immediately` parameter is optional.

For Linux, macOS, or Unix:

```
aws rds --region MY_REGION \
  stop-activity-stream \
  --resource-arn MY_DB_ARN \
  --apply-immediately
```

For Windows:

```
aws rds --region MY_REGION ^
  stop-activity-stream ^
  --resource-arn MY_DB_ARN ^
```

--apply-immediately

RDS API

To stop database activity streams for your database, configure the DB instance using the [StopActivityStream](#) operation. Identify the AWS Region for the DB instance using the Region parameter. The ApplyImmediately parameter is optional.

Monitoring database activity streams

Database activity streams monitor and report activities. The stream of activity is collected and transmitted to Amazon Kinesis. From Kinesis, you can monitor the activity stream, or other services and applications can consume the activity stream for further analysis. You can find the underlying Kinesis stream name by using the AWS CLI command `describe-db-instances` or the RDS API `DescribeDBInstances` operation.

Amazon RDS manages the Kinesis stream for you as follows:

- Amazon RDS creates the Kinesis stream automatically with a 24-hour retention period.
- Amazon RDS scales the Kinesis stream if necessary.
- If you stop the database activity stream or delete the DB instance, Amazon RDS deletes the Kinesis stream.

The following categories of activity are monitored and put in the activity stream audit log:

- **SQL commands** – All SQL commands are audited, and also prepared statements, built-in functions, and functions in PL/SQL. Calls to stored procedures are audited. Any SQL statements issued inside stored procedures or functions are also audited.
- **Other database information** – Activity monitored includes the full SQL statement, the row count of affected rows from DML commands, accessed objects, and the unique database name. Database activity streams also monitor the bind variables and stored procedure parameters.

Important

The full SQL text of each statement is visible in the activity stream audit log, including any sensitive data. However, database user passwords are redacted if Oracle can determine them from the context, such as in the following SQL statement.

ALTER ROLE role-name WITH password

- **Connection information** – Activity monitored includes session and network information, the server process ID, and exit codes.

If an activity stream has a failure while monitoring your DB instance, you are notified through RDS events.

Topics

- [Accessing an activity stream from Kinesis \(p. 738\)](#)
- [Audit log contents and examples \(p. 739\)](#)
- [Processing a database activity stream using the AWS SDK \(p. 752\)](#)

Accessing an activity stream from Kinesis

When you enable an activity stream for a database, a Kinesis stream is created for you. From Kinesis, you can monitor your database activity in real time. To further analyze database activity, you can

connect your Kinesis stream to consumer applications. You can also connect the stream to compliance management applications such as IBM's Security Guardium or Imperva's SecureSphere Database Audit and Protection.

You can access your Kinesis stream either from the RDS console or the Kinesis console.

To access an activity stream from Kinesis using the RDS console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the RDS for Oracle instance on which you started an activity stream.
4. Choose **Configuration**.
5. Under **Database activity stream**, choose the link under **Kinesis stream**.
6. In the Kinesis console, choose **Monitoring** to begin observing the database activity.

To access an activity stream from Kinesis using the Kinesis console

1. Open the Kinesis console at <https://console.aws.amazon.com/kinesis>.
2. Choose your activity stream from the list of Kinesis streams.

An activity stream's name includes the prefix aws-rds-das-db- followed by the resource ID of the database. The following is an example.

```
aws-rds-das-db-NHV0V4PCLWHGF52NP
```

To use the Amazon RDS console to find the resource ID for the database, choose your DB instance from the list of databases, and then choose the **Configuration** tab.

To use the AWS CLI to find the full Kinesis stream name for an activity stream, use a [describe-db-instances](#) CLI request and note the value of ActivityStreamKinesisStreamName in the response.

3. Choose **Monitoring** to begin observing the database activity.

For more information about using Amazon Kinesis, see [What Is Amazon Kinesis Data Streams?](#).

Audit log contents and examples

Monitored events are represented in the database activity stream as JSON strings. The structure consists of a JSON object containing a **DatabaseActivityMonitoringRecord**, which in turn contains a **databaseActivityEventList** array of activity events.

Topics

```

DatabaseActivityMonitoringRecords JSON object

The database activity event records are in a JSON object that contains the following information.

JSON Field	Data Type	Description
type	string	The type of JSON record. The value is DatabaseActivityMonitoringRecords.
version	string	The version of the database activity monitoring records. Oracle DB uses version 1.3. This version introduces the engineNativeAuditFields JSON object.
databaseActivityEvents <small>(String)</small>	string	A JSON object containing the activity events.
key	string	An encryption key you use to decrypt the databaseActivityEventList (p. 747) databaseActivityEventList JSON array.

databaseActivityEvents JSON Object

The databaseActivityEvents JSON object contains the following information.

Top-level fields in JSON record

Each event in the audit log is wrapped inside a record in JSON format. This record contains the following fields.

type

This field always has the value `DatabaseActivityMonitoringRecords`.

version

This field represents the version of the database activity stream data protocol or contract. It defines which fields are available.

databaseActivityEvents

An encrypted string representing one or more activity events. It's represented as a base64 byte array. When you decrypt the string, the result is a record in JSON format with fields as shown in the examples in this section.

key

The encrypted data key used to encrypt the `databaseActivityEvents` string. This is the same AWS KMS key that you provided when you started the database activity stream.

The following example shows the format of this record.

```
{
  "type": "DatabaseActivityMonitoringRecords",
  "version": "1.3",
  "databaseActivityEvents": "encrypted audit records",
  "key": "encrypted key"
}
```

Take the following steps to decrypt the contents of the `databaseActivityEvents` field:

1. Decrypt the value in the `key` JSON field using the KMS key you provided when starting database activity stream. Doing so returns the data encryption key in clear text.
2. Base64-decode the value in the `databaseActivityEvents` JSON field to obtain the ciphertext, in binary format, of the audit payload.
3. Decrypt the binary ciphertext with the data encryption key that you decoded in the first step.
4. Decompress the decrypted payload.
 - The encrypted payload is in the `databaseActivityEvents` field.
 - The `databaseActivityEventList` field contains an array of audit records. The `type` fields in the array can be `record` or `heartbeat`.

The audit log activity event record is a JSON object that contains the following information.

JSON Field	Data Type	Description
<code>type</code>	string	The type of JSON record. The value is <code>DatabaseActivityMonitoringRecord</code> .
<code>instanceId</code>	string	The DB instance resource identifier. It corresponds to the DB instance attribute <code>DbiResourceId</code> .
<code>databaseActivityEventList</code> (Page 747)		An array of activity audit records or heartbeat messages.

databaseActivityEventList JSON array

The audit log payload is an encrypted databaseActivityEventList JSON array. The following table lists alphabetically the fields for each activity event in the decrypted DatabaseActivityEventList array of an audit log.

When unified auditing is enabled in Oracle Database, the audit records are populated in this new audit trail. The UNIFIED_AUDIT_TRAIL view displays audit records in tabular form by retrieving the audit records from the audit trail. When you start a database activity stream, a column in UNIFIED_AUDIT_TRAIL maps to a field in the databaseActivityEventList array.

Important

The event structure is subject to change. Amazon RDS might add new fields to activity events in the future. In applications that parse the JSON data, make sure that your code can ignore or take appropriate actions for unknown field names.

databaseActivityEventList fields for Amazon RDS for Oracle

Field	Data Type	Source	Description
class	string	AUDIT_TYPE column in UNIFIED_AUDIT_TRAIL	<p>The class of activity event. This corresponds to the AUDIT_TYPE column in the UNIFIED_AUDIT_TRAIL view. Valid values for Amazon RDS for Oracle are the following:</p> <ul style="list-style-type: none"> • Standard • FineGrainedAudit • XS • Database Vault • Label Security • RMAN_AUDIT • Datapump • Direct path API <p>For more information, see UNIFIED_AUDIT_TRAIL in the Oracle documentation.</p>
clientApplication	string	CLIENT_PROGRAM_NAME in UNIFIED_AUDIT_TRAIL	The application the client used to connect as reported by the client. The client doesn't have to provide this information, so the value can be null. A sample value is JDBC Thin Client.
command	string	ACTION_NAME column in UNIFIED_AUDIT_TRAIL	Name of the action executed by the user. To understand the complete action, read both the command name and the AUDIT_TYPE value. A sample value is ALTER DATABASE.

Field	Data Type	Source	Description
commandText	string	SQL_TEXT column in UNIFIED_AUDIT_TRAIL	The SQL statement associated with the event. A sample value is ALTER DATABASE BEGIN BACKUP.
databaseName	string	NAME column in V\$DATABASE	The name of the database.
dbid	number	DBID column in UNIFIED_AUDIT_TRAIL	Numerical identifier for the database. A sample value is 1559204751.
dbProtocol	string	N/A	The database protocol. In this beta, the value is oracle.
dbUserName	string	DBUSERNAME column in UNIFIED_AUDIT_TRAIL	Name of the database user whose actions were audited. A sample value is RDSADMIN.
endTime	string	N/A	This field isn't used for RDS for Oracle and is always null.

Field	Data Type	Source	Description
engineNativeAuditFields	object	UNIFIED_AUDIT_TRAIL	<p>By default, this object is empty. Field	Data Type	Source	Description
			OS_USERNAME PROTOCOL_ACTION_NAME PROTOCOL_MESSAGE PROTOCOL_RETURN_CODE PROTOCOL_SESSION_ID PROTOCOL_USERHOST PROXY_SESSIONID RLS_INFO RMAN_DEVICE_TYPE RMAN_OBJECT_TYPE RMAN_OPERATION RMAN_SESSION_RECID RMAN_SESSION_STAMP ROLE SCN SYSTEM_PRIVILEGE SYSTEM_PRIVILEGE_USED TARGET_USER TERMINAL UNIFIED_AUDIT_POLICIES USERHOST XS_CALLBACK_EVENT_TYPE XS_COOKIE XS_DATASEC_POLICY_NAME XS_ENABLED_ROLE XS_ENTITY_TYPE XS_INACTIVITY_TIMEOUT XS_NS_ATTRIBUTE XS_NS_ATTRIBUTE_NEW_VAL XS_NS_ATTRIBUTE_OLD_VAL XS_NS_NAME XS_PACKAGE_NAME XS_PROCEDURE_NAME XS_PROXY_USER_NAME XS_SCHEMA_NAME XS_SESSIONID XS_TARGET_PRINCIPAL_NAME XS_USER_NAME
			For more information, see UNIFIED_AUDIT_TRAIL in the Oracle Database documentation.
errorMessage	string	N/A	This field isn't used for RDS for Oracle and is always null.
exitCode	number	RETURN_CODE column in UNIFIED_AUDIT_TRAIL	Oracle Database error code generated by the action. If the action succeeded, the value is 0.
logTime	string	EVENT_TIMESTAMP_UTC column in UNIFIED_AUDIT_TRAIL	Timestamp of the creation of the audit trail entry. A sample value is 2020-11-27 06:56:14.981404.

Field	Data Type	Source	Description
netProtocol	string	AUTHENTICATION_TYPE column in UNIFIED_AUDIT_TRAIL	The network communication protocol. A sample value is TCP.
objectName	string	OBJECT_NAME column in UNIFIED_AUDIT_TRAIL	The name of the object affected by the action. A sample value is employees.
objectType	string	OBJECT_SCHEMA column in UNIFIED_AUDIT_TRAIL	The schema name of object affected by the action. A sample value is hr.
paramList	list	SQL_BINDS column in UNIFIED_AUDIT_TRAIL	The list of bind variables, if any, associated with SQL_TEXT. A sample value is parameter_1,parameter_2.
pid	number	OS_PROCESS column in UNIFIED_AUDIT_TRAIL	Operating system process identifier of the Oracle database process. A sample value is 22396.
remoteHost	string	AUTHENTICATION_TYPE column in UNIFIED_AUDIT_TRAIL	Either the client IP address or name of the host from which the session was spawned. A sample value is 123.456.789.123.
remotePort	string	AUTHENTICATION_TYPE column in UNIFIED_AUDIT_TRAIL	The client port number. A typical value in Oracle Database environments is 1521.
rowCount	number	N/A	This field isn't used for RDS for Oracle and is always null.
serverHost	string	Database host	The IP address of the database server host. A sample value is 123.456.789.123.
serverType	string	N/A	The database server type. The value is always ORACLE.
serverVersion	string	Database host	The Amazon RDS for Oracle version, Release Update (RU), and Release Update Revision (RUR). A sample value is 19.0.0.0.ru-2020-01.rur-2020-01.r1
serviceName	string	Database host	The name of the service. A sample value is oracle-ee.
sessionId	number	SESSIONID column in UNIFIED_AUDIT_TRAIL	The session identifier of the audit. An example is 1894327130.

Field	Data Type	Source	Description
startTime	string	N/A	This field isn't used for RDS for Oracle and is always null.
statementId	number	STATEMENT_ID column in UNIFIED_AUDIT_TRAIL	Numeric ID for each statement run. A statement can cause many actions. A sample value is 142197.
substatementId	N/A	N/A	This field isn't used for RDS for Oracle and is always null.
transactionId	string	TRANSACTION_ID column in UNIFIED_AUDIT_TRAIL	The identifier of the transaction in which the object is modified. A sample value is 02000800D5030000.

Processing a database activity stream using the AWS SDK

You can programmatically process an activity stream by using the AWS SDK.

Managing access to database activity streams

Any user with appropriate AWS Identity and Access Management (IAM) role privileges for database activity streams can create, start, stop, and modify the activity stream settings for a DB instance. These actions are included in the audit log of the stream. For best compliance practices, we recommend that you don't provide these privileges to DBAs.

You set access to database activity streams using IAM policies. For more information about RDS for Oracle authentication, see [Identity and access management for Amazon RDS \(p. 2016\)](#). For more information about creating IAM policies, see [Creating and using an IAM policy for IAM database access \(p. 2051\)](#).

Example Policy to allow configuring database activity streams

To give users fine-grained access to modify activity streams, use the service-specific operation context keys `rds:StartActivityStream` and `rds:StopActivityStream` in an IAM policy. The following IAM policy example allows a user or role to configure activity streams.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ConfigureActivityStreams",
            "Effect": "Allow",
            "Action": [
                "rds:StartActivityStream",
                "rds:StopActivityStream"
            ],
            "Resource": "*",
        }
    ]
}
```

Example Policy to allow starting database activity streams

The following IAM policy example allows a user or role to start activity streams.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowStartActivityStreams",  
            "Effect": "Allow",  
            "Action": "rds:StartActivityStream",  
            "Resource": "*"  
        }  
    ]  
}
```

Example Policy to allow stopping database activity streams

The following IAM policy example allows a user or role to stop activity streams.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowStopActivityStreams",  
            "Effect": "Allow",  
            "Action": "rds:StopActivityStream",  
            "Resource": "*"  
        }  
    ]  
}
```

Example Policy to deny starting database activity streams

The following IAM policy example prevents a user or role from starting activity streams.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DenyStartActivityStreams",  
            "Effect": "Deny",  
            "Action": "rds:StartActivityStream",  
            "Resource": "*"  
        }  
    ]  
}
```

Example Policy to deny stopping database activity streams

The following IAM policy example prevents a user or role from stopping activity streams.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DenyStopActivityStreams",  
            "Effect": "Deny",  
            "Action": "rds:StopActivityStream",  
            "Resource": "*"  
        }  
    ]  
}
```

]
}

Working with Amazon RDS Custom

Amazon RDS Custom automates database administration tasks and operations. RDS Custom makes it possible for you as a database administrator to access and customize your database environment and operating system. With RDS Custom, you can customize to meet the requirements of legacy, custom, and packaged applications.

The following video is an overview of Amazon RDS Custom from AWS re:Invent 2021.

Topics

- [Addressing the challenge of database customization \(p. 755\)](#)
- [Management model and benefits for Amazon RDS Custom \(p. 756\)](#)
- [Amazon RDS Custom architecture \(p. 758\)](#)
- [Security considerations for Amazon RDS Custom \(p. 762\)](#)
- [Working with RDS Custom for Oracle \(p. 763\)](#)
- [Working with RDS Custom for SQL Server \(p. 843\)](#)
- [Troubleshooting DB issues for Amazon RDS Custom \(p. 889\)](#)

Addressing the challenge of database customization

Amazon RDS Custom brings the benefits of Amazon RDS to a market that can't easily move to a fully managed service because of customizations that are required with third-party applications. Amazon RDS Custom saves administrative time, is durable, and scales with your business.

If you need the entire database and operating system to be fully managed by AWS, we recommend Amazon RDS. If you need administrative rights to the database and underlying operating system to make dependent applications available, Amazon RDS Custom is the better choice. If you want full management responsibility and simply need a managed compute service, the best option is self-managing your commercial databases on Amazon EC2.

To deliver a managed service experience, Amazon RDS doesn't let you access the underlying host. Amazon RDS also restricts access to some procedures and objects that require high-level privileges. However, for some applications, you might need to perform operations as a privileged operating system (OS) user.

For example, you might need to do the following:

- Install custom database and OS patches and packages.
- Configure specific database settings.
- Configure file systems to share files directly with their applications.

Previously, if you needed to customize your application, you had to deploy your database on-premises or on Amazon EC2. In this case, you bear most or all of the responsibility for database management, as summarized in the following table.

Feature	On-premises responsibility	Amazon EC2 responsibility	Amazon RDS responsibility
Application optimization	Customer	Customer	Customer
Scaling	Customer	Customer	AWS
High availability	Customer	Customer	AWS
Database backups	Customer	Customer	AWS
Database software patching	Customer	Customer	AWS
Database software install	Customer	Customer	AWS
OS patching	Customer	Customer	AWS
OS installation	Customer	Customer	AWS
Server maintenance	Customer	AWS	AWS
Hardware lifecycle	Customer	AWS	AWS
Power, network, and cooling	Customer	AWS	AWS

When you manage database software yourself, you gain more control, but you're also more prone to user errors. For example, when you make changes manually, you might accidentally cause application downtime. You might spend hours checking every change to identify and fix an issue. Ideally, you want a managed database service that automates common DBA tasks, but also supports privileged access to the database and underlying operating system.

Management model and benefits for Amazon RDS Custom

Amazon RDS Custom is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. Amazon RDS Custom automates setup, operation, and scaling of databases in the AWS Cloud while granting you access to the database and underlying operating system. With this access, you can configure settings, install patches, and enable native features to meet the dependent application's requirements. With RDS Custom, you can run your database workload using the AWS Management Console or the AWS CLI.

Currently, Amazon RDS Custom supports only the Oracle Database and Microsoft SQL Server engines.

Shared responsibility model

With Amazon RDS Custom, you get the automation of Amazon RDS and the flexibility of Amazon EC2. You take on additional database management responsibilities beyond what you do in Amazon RDS. By doing so, you can benefit from RDS automation and the deeper customization of EC2. To meet your application and business requirements, you manage the host yourself.

In the shared responsibility model of RDS Custom, you get more control than in Amazon RDS but also more responsibility. Shared responsibility has two meanings:

1. You own part of the process when using a feature.
2. You have full access to the feature, and it's your responsibility to make sure that any customizations work with that feature.

The following table details the shared responsibility model for RDS Custom.

Feature	Amazon EC2 responsibility	Amazon RDS responsibility	RDS Custom for Oracle responsibility	RDS Custom for SQL Server responsibility
Application optimization	Customer	Customer	Customer	Customer
Scaling	Customer	AWS	Shared	Shared
High availability	Customer	AWS	Customer	Customer
Database backups	Customer	AWS	Shared	Shared
Database software patching	Customer	AWS	Shared	AWS
Database software install	Customer	AWS	Shared	AWS
OS patching	Customer	AWS	Customer	AWS
OS installation	Customer	AWS	Shared	AWS
Server maintenance	AWS	AWS	AWS	AWS
Hardware lifecycle	AWS	AWS	AWS	AWS
Power, network, and cooling	AWS	AWS	AWS	AWS

You can create an RDS Custom DB instance using Microsoft SQL Server. In this case:

- You don't manage your own media.
- You don't need to purchase SQL Server licenses separately. AWS holds the license for the SQL Server database software.

You can create an RDS Custom DB instance using Oracle Database. In this case, you do the following:

- Manage your own media.

When using RDS Custom, you upload your own database installation files and patches. You create a custom engine version (CEV) from these files. Then you can create an RDS Custom DB instance by using this CEV.

- Manage your own licenses.

You bring your own Oracle Database licenses and manage licenses by yourself.

Key benefits of RDS Custom

With RDS Custom, you can do the following:

- Automate many of the same administrative tasks as Amazon RDS, including the following:
 - Lifecycle management of databases
 - Automated backups and point-in-time recovery (PITR)
 - Monitoring the health of RDS Custom DB instances and observing changes to the infrastructure, operating system, and databases
 - Notification or taking action to fix issues depending on disruption to the DB instance
- Install third-party applications.

You can install software to run custom applications and agents. Because you have privileged access to the host, you can modify file systems to support legacy applications.

- Install custom patches.

You can apply custom database patches or modify OS packages on your RDS Custom DB instances.

- Stage an on-premises database before moving it to a fully managed service.

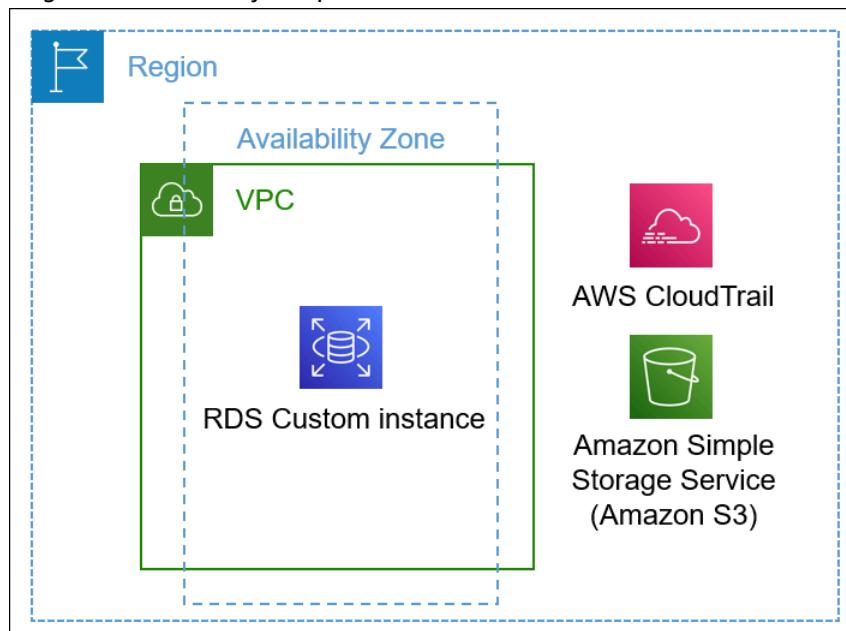

If you manage your own on-premises database, you can stage the database to RDS Custom as-is. After you familiarize yourself with the cloud environment, you can migrate your database to a fully managed Amazon RDS DB instance.

- Create your own automation.

You can create, schedule, and run custom automation scripts for reporting, management, or diagnostic tools.

Amazon RDS Custom architecture

Amazon RDS Custom architecture is based on Amazon RDS, with important differences. The following diagram shows the key components of the RDS Custom architecture.

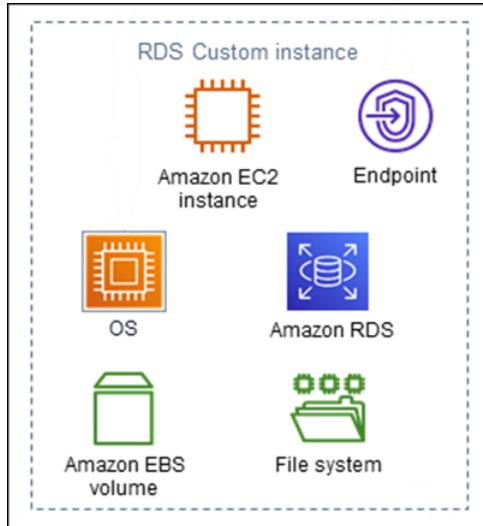

Topics

- [VPC \(p. 759\)](#)
- [Amazon S3 \(p. 759\)](#)
- [AWS CloudTrail \(p. 760\)](#)
- [RDS Custom automation and monitoring \(p. 760\)](#)

VPC

As in Amazon RDS, your RDS Custom DB instance resides in a virtual private cloud (VPC).

The DB instance consists of the following main components:

- Amazon EC2 instance
- Instance endpoint
- Operating system installed on the Amazon EC2 instance
- Amazon EBS storage, which contains any additional file systems

Amazon S3

If you use RDS Custom for Oracle, you upload installation media to a user-created Amazon S3 bucket. RDS Custom for Oracle uses the media in this bucket to create a custom engine version (CEV). A CEV is a binary volume snapshot of a database version and Amazon Machine Image (AMI). From the CEV, you can create an RDS Custom DB instance. For more information, see [Working with custom engine versions for Amazon RDS Custom for Oracle \(p. 781\)](#).

For both RDS Custom for Oracle and RDS Custom for SQL Server, RDS Custom automatically creates an Amazon S3 bucket prefixed with the string `do-not-delete-rds-custom-`. RDS Custom uses the `do-not-delete-rds-custom-` S3 bucket to store the following types of files:

- AWS CloudTrail logs for the trail created by RDS Custom
- Support perimeter artifacts (see [Support perimeter \(p. 761\)](#))
- Database redo log files (RDS Custom for Oracle only)
- Transaction logs (RDS Custom for SQL Server only)
- Custom engine version artifacts (RDS Custom for Oracle only)

RDS Custom creates the do-not-delete-rds-custom- S3 bucket when you create either of the following resources:

- Your first CEV for RDS Custom for Oracle
- Your first DB instance for RDS Custom for SQL Server

RDS Custom creates one bucket for each combination of the following:

- AWS account ID
- Engine type (either RDS Custom for Oracle or RDS Custom for SQL Server)
- AWS Region

For example, if you create RDS Custom for Oracle CEVs in a single AWS Region, one do-not-delete-rds-custom- bucket exists. If you create multiple RDS Custom for SQL Server instances, and they reside in different AWS Regions, one do-not-delete-rds-custom- bucket exists in each AWS Region. If you create one RDS Custom for Oracle instance and two RDS Custom for SQL Server instances in a single AWS Region, two do-not-delete-rds-custom- buckets exist.

AWS CloudTrail

RDS Custom automatically creates an AWS CloudTrail trail whose name begins with do-not-delete-rds-custom-. The RDS Custom support perimeter relies on the events from CloudTrail to determine whether your actions affect RDS Custom automation. For more information, see [Support perimeter \(p. 761\)](#).

RDS Custom creates the trail when you create your first DB instance. RDS Custom creates one trail for each combination of the following:

- AWS account ID
- Engine type (either RDS Custom for Oracle or RDS Custom for SQL Server)
- AWS Region

RDS Custom automation and monitoring

RDS Custom has automation software that runs outside of the DB instance. This software communicates with agents on the DB instance and with other components within the overall RDS Custom environment.

Monitoring and recovery

The RDS Custom monitoring and recovery features offer similar functionality to Amazon RDS. By default, RDS Custom is in full automation mode. The automation software has the following primary responsibilities:

- Collect metrics and send notifications
- Perform automatic instance recovery

An important responsibility of RDS Custom automation is responding to problems with your Amazon EC2 instance. For various reasons, the host might become impaired or unreachable. RDS Custom resolves these problems by either rebooting or replacing the Amazon EC2 instance.

The automated replacement preserves all database data. On RDS Custom for SQL Server, host replacement doesn't preserve operating system customizations or data on the C: drive.

The only customer-visible change when a host is replaced is a new public IP address. For more information, see [How Amazon RDS Custom replaces an impaired host \(p. 897\)](#).

Support perimeter

RDS Custom provides additional monitoring capability called the *support perimeter*. This additional monitoring ensures that your RDS Custom instance uses a supported AWS infrastructure, operating system, and database. For more information about the support perimeter, see [RDS Custom support perimeter and unsupported configurations \(p. 891\)](#).

Security considerations for Amazon RDS Custom

When you create an Amazon RDS Custom for Oracle custom engine version (CEV) or an RDS Custom for SQL Server DB instance, RDS Custom creates an Amazon S3 bucket. The S3 bucket stores files such as CEV artifacts, redo (transaction) logs, configuration items for the support perimeter, and AWS CloudTrail logs.

You can make these S3 buckets more secure by using the global condition context keys to prevent the *confused deputy problem*. For more information, see [Preventing cross-service confused deputy problems \(p. 2046\)](#).

The following RDS Custom for Oracle example shows the use of the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in an S3 bucket policy. For RDS Custom for Oracle, make sure to include the Amazon Resource Names (ARNs) for the CEVs and the DB instances. For RDS Custom for SQL Server, make sure to include the ARN for the DB instances.

Working with RDS Custom for Oracle

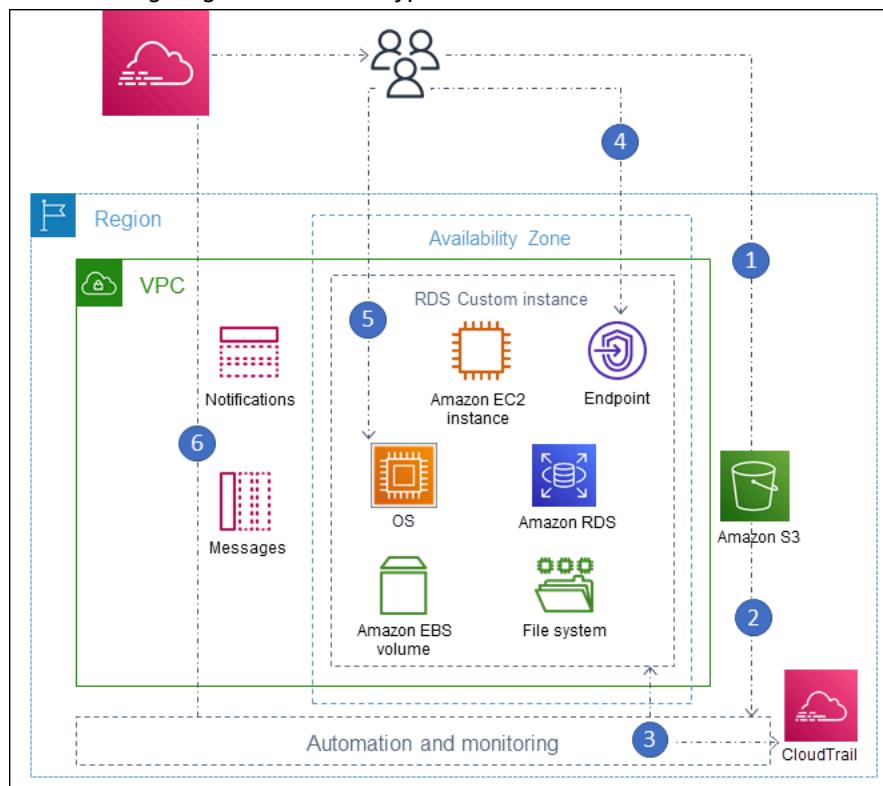

Following, you can find instructions for creating, managing, and maintaining your RDS Custom for Oracle DB instances.

Topics

- [RDS Custom for Oracle workflow \(p. 763\)](#)
- [Availability and requirements for Amazon RDS Custom for Oracle \(p. 766\)](#)
- [Setting up your environment for Amazon RDS Custom for Oracle \(p. 768\)](#)
- [Working with custom engine versions for Amazon RDS Custom for Oracle \(p. 781\)](#)
- [Configuring a DB instance for Amazon RDS Custom for Oracle \(p. 807\)](#)
- [Managing an Amazon RDS Custom for Oracle DB instance \(p. 816\)](#)
- [Working with Oracle replicas for RDS Custom for Oracle \(p. 826\)](#)
- [Backing up and restoring an Amazon RDS Custom for Oracle DB instance \(p. 831\)](#)
- [Upgrading a DB instance for Amazon RDS Custom for Oracle \(p. 838\)](#)

RDS Custom for Oracle workflow

The following diagram shows the typical workflow for RDS Custom for Oracle.

The steps are as follows:

1. Upload your database software to your Amazon S3 bucket.

For more information, see [Uploading your installation files to Amazon S3 \(p. 786\)](#).

2. Create an RDS Custom custom engine version (CEV) from your media.

For more information, see [Creating a CEV \(p. 798\)](#).

3. Create an RDS Custom DB instance from a CEV.

For more information, see [Creating an RDS Custom for Oracle DB instance \(p. 808\)](#).

4. Connect your application to the RDS Custom DB instance endpoint.

For more information, see [Connecting to your RDS Custom DB instance using SSH \(p. 812\)](#) and [Connecting to your RDS Custom DB instance using AWS Systems Manager \(p. 814\)](#).

5. (Optional) Access the host to customize your software.

6. Monitor notifications and messages generated by RDS Custom automation.

Database installation files

Your responsibility for media is a key difference between Amazon RDS and RDS Custom. Amazon RDS, which is a fully managed service, supplies the Amazon Machine Image (AMI) and database software. The Amazon RDS database software is preinstalled, so you need only choose a database engine and version, and create your database.

For RDS Custom, you supply your own media. When you create a custom engine version, RDS Custom installs the media that you provide. RDS Custom media contains your database installation files and patches. This service model is called *Bring Your Own Media (BYOM)*.

Custom engine version

An *RDS Custom custom engine version (CEV)* is a binary volume snapshot of a database version and AMI. You store your database installation files in Amazon S3. When you create your CEV, you specify the files in a JSON document called a *CEV manifest*. You can also specify installation parameters that set nondefault values for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group.

Name your CEV using a customer-specified string. The name format is the following, depending on your Oracle Database release:

- 19.*customized_string*
- 18.*customized_string*
- 12.2.*customized_string*
- 12.1.*customized_string*

You can use 1–50 alphanumeric characters, underscores, dashes, and periods. For example, you might name your CEV 19.my_cev1. When you create a CEV, you can specify the Oracle Multitenant option. You can create container databases (CDBs) only when the CEV was created with the Oracle Multitenant option. For more information, see [Working with custom engine versions for Amazon RDS Custom for Oracle \(p. 781\)](#).

Creating a DB instance for RDS Custom for Oracle

After you create your CEV, it's available for use. You can create multiple CEVs, and you can create multiple RDS Custom for Oracle DB instances from any CEV. You can also change the status of a CEV to make it available or inactive.

You can either create your RDS Custom for Oracle DB instance with the Oracle Multitenant architecture (custom-oracle-ee-cdb engine type) or with the traditional non-CDB architecture (custom-oracle-ee engine type). When you create a container database (CDB), it contains one pluggable database (PDB) and one PDB seed. You can create additional PDBs manually using Oracle SQL.

To create your RDS Custom for Oracle DB instance, use the `create-db-instance` command. In this command, specify which CEV to use. The procedure is similar to creating an Amazon RDS DB instance. However, some parameters are different. For more information, see [Configuring a DB instance for Amazon RDS Custom for Oracle \(p. 807\)](#).

Database connection

Like an Amazon RDS DB instance, an RDS Custom DB instance resides in a virtual private cloud (VPC). Your application connects to the Oracle database using an Oracle listener.

If your database is a CDB, you can use the listener `L_RDSCDB_001` to connect to the CDB root and to a PDB. If you plug a non-CDB into a CDB, make sure to set `USE_SID_AS_SERVICE_LISTENER = ON` so that migrated applications keep the same settings.

When you connect to a non-CDB, the master user is the user for the non-CDB. When you connect to a CDB, the master user is the user for the PDB. To connect to the CDB root, log in to the host, start a SQL client, and create an administrative user with SQL commands.

RDS Custom customization

You can access the RDS Custom host to install or customize software. To avoid conflicts between your changes and the RDS Custom automation, you can pause the automation for a specified period. During this period, RDS Custom doesn't perform monitoring or instance recovery. At the end of the period, RDS Custom resumes full automation. For more information, see [Pausing and resuming RDS Custom automation \(p. 817\)](#).

Availability and requirements for Amazon RDS Custom for Oracle

In this topic, you can find a summary of the Amazon RDS Custom for Oracle feature availability and requirements for quick reference.

Topics

- [Region and version availability \(p. 766\)](#)
- [DB instance class support for RDS Custom for Oracle \(p. 766\)](#)
- [General requirements for RDS Custom for Oracle \(p. 766\)](#)
- [Limitations for RDS Custom for Oracle \(p. 766\)](#)

Region and version availability

Feature availability and support vary across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS Custom for Oracle, see [RDS Custom \(p. 110\)](#).

DB instance class support for RDS Custom for Oracle

RDS Custom for Oracle supports the following DB instance classes:

- db.m5.large–db.m5.24xlarge
- db.r5.large–db.r5.24xlarge

General requirements for RDS Custom for Oracle

Make sure to follow these requirements for Amazon RDS Custom for Oracle:

- Use [Oracle Software Delivery Cloud](#) to download Oracle installation and patch files. For more information, see [Prerequisites for creating an RDS Custom for Oracle instance \(p. 768\)](#).
- Use the DB instance classes shown in [DB instance class support for RDS Custom for Oracle \(p. 766\)](#). The instances must run Oracle Linux 7 Update 6. The only storage types supported are solid state drives (SSD) of types gp2 and io1. The maximum storage limit is 64 TiB.
- Make sure that you have an AWS KMS key to create an RDS Custom DB instance. For more information, see [Make sure that you have a symmetric encryption AWS KMS key \(p. 768\)](#).
- Use only the approved database installation and patch files. For more information, see [Downloading your database installation files and patches from Oracle Software Delivery Cloud \(p. 781\)](#).
- Create an AWS Identity and Access Management (IAM) role and instance profile. For more information, see [Configuring IAM and your VPC \(p. 769\)](#).
- Make sure to supply a networking configuration that RDS Custom can use to access other AWS services. For specific requirements, see [Configuring IAM and your VPC \(p. 769\)](#).
- Make sure that the combined number of RDS Custom and Amazon RDS DB instances doesn't exceed your quota limit. For example, if your quota for Amazon RDS is 40 DB instances, you can have 20 RDS Custom for Oracle DB instances and 20 Amazon RDS DB instances.

Limitations for RDS Custom for Oracle

The following limitations apply to RDS Custom for Oracle:

- You can't provide your own AMI.
- Not all options are supported. For example, when you create or modify an RDS Custom for Oracle DB instance, you can't do the following:
 - Change the number of CPU cores and threads per core on the DB instance class.
 - Turn on storage autoscaling.
 - Set backup retention to 0.
 - Configure Kerberos authentication.
 - Specify your own DB parameter group or option group.
 - Turn on Performance Insights.
 - Turn on automatic minor version upgrade.
- Change the DB instance class. For example, you can't change a db.m5.xlarge DB instance to db.m5.2xlarge. However, you can restore a snapshot of your RDS Custom for Oracle DB instance to a different instance class.
- The maximum DB instance storage is 64 TiB.
- Only one database is supported on an RDS Custom for Oracle DB instance.

Setting up your environment for Amazon RDS Custom for Oracle

Before you create a DB instance based on Amazon RDS Custom for Oracle, perform the following tasks.

Topics

- [Prerequisites for creating an RDS Custom for Oracle instance \(p. 768\)](#)
- [Make sure that you have a symmetric encryption AWS KMS key \(p. 768\)](#)
- [Download and install the AWS CLI \(p. 769\)](#)
- [Configuring IAM and your VPC \(p. 769\)](#)
- [Grant required permissions to your IAM user \(p. 778\)](#)

Prerequisites for creating an RDS Custom for Oracle instance

Before creating an RDS Custom for Oracle DB instance, make sure that you meet the following prerequisites:

- You have access to [My Oracle Support](#) and [Oracle Software Delivery Cloud](#) to download the supported list of installation files and patches for the Enterprise Edition of any of the following Oracle Database releases:
 - Oracle Database 19c
 - Oracle Database 18c
 - Oracle Database 12c Release 2 (12.2)
 - Oracle Database 12c Release 1 (12.1)

If you use an unknown patch, custom engine version (CEV) creation fails. In this case, contact the RDS Custom support team and ask it to add the missing patch.

For more information, see [Downloading your database installation files and patches from Oracle Software Delivery Cloud \(p. 781\)](#).

- You have access to Amazon S3 so that you can upload your Oracle installation files. You use the installation files when you create your RDS Custom CEV.

For more information, see [Uploading your installation files to Amazon S3 \(p. 786\)](#) and [Creating a CEV \(p. 798\)](#).

- You supply your own virtual private cloud (VPC) and security group configuration. For more information, see [Configuring IAM and your VPC \(p. 769\)](#).
- The AWS Identity and Access Management (IAM) user that creates a CEV or RDS Custom DB instance has the required permissions for IAM, CloudTrail, and Amazon S3.

For more information, see [Grant required permissions to your IAM user \(p. 778\)](#).

For each task, the following sections describe the requirements and limitations specific to the task. For example, when you create your RDS Custom DB for Oracle instance, use either the db.m5 or db.r5 instance classes running Oracle Linux 7 Update 6. For general requirements that apply to RDS Custom, see [Availability and requirements for Amazon RDS Custom for Oracle \(p. 766\)](#).

Make sure that you have a symmetric encryption AWS KMS key

A symmetric encryption AWS KMS key is required for RDS Custom. When you create an RDS Custom for Oracle DB instance, you supply the KMS key identifier. For more information, see [Configuring a DB instance for Amazon RDS Custom for Oracle \(p. 807\)](#).

You have the following options:

- If you have an existing KMS key in your AWS account, you can use it with RDS Custom. No further action is necessary.
- If you already created a symmetric encryption KMS key for a different RDS Custom engine, you can reuse the same KMS key. No further action is necessary.
- If you don't have an existing symmetric encryption KMS key in your account, create a KMS key by following the instructions in [Creating keys](#) in the *AWS Key Management Service Developer Guide*.
- If you're creating a CEV or RDS Custom DB instance, and your KMS key is in a different AWS account, make sure to use the AWS CLI. You can't use the AWS console with cross-account KMS keys.

RDS Custom doesn't support AWS-managed KMS keys.

Make sure that the symmetric encryption key that you use gives the AWS Identity and Access Management (IAM) role in your IAM instance profile access to the kms : Decrypt and kms : GenerateDataKey operations. If you have a new symmetric encryption key in your account, no changes are required. Otherwise, make sure that your symmetric encryption key's policy can give access to these operations.

For more information about configuring IAM for RDS Custom for Oracle, see [Configuring IAM and your VPC \(p. 769\)](#).

Download and install the AWS CLI

AWS provides you with a command-line interface to use RDS Custom features. You can use either version 1 or version 2 of the AWS CLI.

For information about downloading and installing the AWS CLI, see [Installing or updating the latest version of the AWS CLI](#).

If you plan to access RDS Custom only from the AWS Management Console, skip this step.

If you have already downloaded the AWS CLI for Amazon RDS or a different RDS Custom engine, skip this step.

Configuring IAM and your VPC

You can configure your IAM role and virtual private cloud (VPC) using either of the following techniques:

- [Configuring IAM and your VPC using AWS CloudFormation \(p. 769\)](#) (recommended)
- Following the procedures in [Creating your IAM role and instance profile manually \(p. 770\)](#) and [Configuring your VPC manually \(p. 774\)](#)

Configuring IAM and your VPC using AWS CloudFormation

To simplify setup, you can use the AWS CloudFormation template files to create CloudFormation stacks. To learn how to create stacks, see [Creating a stack on the AWS CloudFormation console](#) in *AWS CloudFormation User Guide*.

To download the template files

1. Open the context (right-click) menu for the link [custom-oracle-iam.zip](#) and choose **Save Link As**.
2. Save the file to your computer.
3. Repeat the previous steps for the link [custom-vpc.zip](#).

If you already configured your VPC for RDS Custom for SQL Server, skip this step.

To configure IAM using CloudFormation

1. Open the CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
2. Start the Create Stack wizard, and choose **Create Stack**.
3. On the **Specify template** page, do the following:
 - a. For **Template source**, choose **Upload a template file**.
 - b. For **Choose file**, navigate to, then choose `custom-oracle-iam.json`.
 - c. Choose **Next**.
4. On the **Specify stack details** page, do the following:
 - a. For **Stack name**, enter `custom-oracle-iam`.
 - b. Choose **Next**.
5. On the **Configure stack options** page, choose **Next**.
6. On the **Review custom-oracle-iam** page, do the following:
 - a. For **Capabilities**, select the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** check box.
 - b. Choose **Create stack**.

CloudFormation creates the IAM roles that RDS Custom for Oracle requires.

To configure your VPC using CloudFormation

This procedure assumes that you've already used CloudFormation to create your IAM roles.

If you've already configured your VPC for a different RDS Custom engine, skip this step.

1. Open the CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
2. On the **Stacks** page, for **Create stack** choose **With new resources (standard)**.
3. On the **Specify template** page, do the following:
 - a. For **Template source**, choose **Upload a template file**.
 - b. For **Choose file**, go to and choose `custom-vpc.json`.
 - c. Choose **Next**.
4. On the **Specify stack details** page, do the following:
 - a. For **Stack name**, enter `custom-vpc`.
 - b. For **Parameters**, choose the private subnets to use for RDS Custom DB instances.
 - c. Choose the private VPC ID to use for RDS Custom DB instances.
 - d. Enter the route table associated with the private subnets.
 - e. Choose **Next**.
5. On the **Configure stack options** page, choose **Next**.
6. On the **Review custom-vpc** page, choose **Create stack**.

CloudFormation configures your VPC.

Creating your IAM role and instance profile manually

To use RDS Custom, you create an IAM instance profile named `AWSRDSCustomInstanceProfileForRdsCustomInstance`. You also create the IAM role

AWSRDSCustomInstanceRoleForRdsCustomInstance for the instance profile. You then add AWSRDSCustomInstanceRoleForRdsCustomInstance to your instance profile.

The following section explains how to perform the task without using CloudFormation.

To create the RDS Custom instance profile and add the necessary role to it

1. Create the IAM role named AWSRDSCustomInstanceRoleForRdsCustomInstance with a trust policy that Amazon EC2 can use to assume this role.
2. Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance.
3. Create an IAM instance profile for RDS Custom named AWSRDSCustomInstanceProfileForRdsCustomInstance.
4. Add the AWSRDSCustomInstanceRoleForRdsCustomInstance IAM role to the instance profile.

Create the role AWSRDSCustomInstanceRoleForRdsCustomInstance

The following example creates the role AWSRDSCustomInstanceRoleForRdsCustomInstance. Using the trust policy, Amazon EC2 can assume the role.

```
aws iam create-role \
--role-name AWSRDSCustomInstanceRoleForRdsCustomInstance \
--assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": "sts:AssumeRole",
            "Effect": "Allow",
            "Principal": {
                "Service": "ec2.amazonaws.com"
            }
        }
    ]
}'
```

Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance

When you embed an inline policy in an IAM role, the inline policy is used as part of the role's access (permissions) policy. You create the AWSRDSCustomIamRolePolicy policy that permits Amazon EC2 to send and receive messages and perform various actions.

The following example creates the access policy named AWSRDSCustomIamRolePolicy, and adds it to the IAM role AWSRDSCustomInstanceRoleForRdsCustomInstance. This example assumes that you have set the \$REGION and \$ACCOUNT_ID variables in the AWS CLI. This example also requires the Amazon Resource Name (ARN) of the AWS KMS key that you want to use for your RDS Custom DB instances.

To specify more than one KMS key, add it to the Resources section of statement ID (Sid) 11.

```
aws iam put-role-policy \
--role-name AWSRDSCustomInstanceRoleForRdsCustomInstance \
--policy-name AWSRDSCustomIamRolePolicy \
--policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "1",
            "Effect": "Allow",
            "Action": [
                "ssm:DescribeAssociation",
                "ssm:PutAssociationResult"
            ],
            "Resource": [
                "arn:aws:kms:$REGION:$ACCOUNT_ID/*"
            ]
        }
    ]
}'
```

```
    "ssm:GetDeployablePatchSnapshotForInstance",
    "ssm:GetDocument",
    "ssm:DescribeDocument",
    "ssm:GetManifest",
    "ssm:GetParameter",
    "ssm:GetParameters",
    "ssm>ListAssociations",
    "ssm>ListInstanceAssociations",
    "ssm:PutInventory",
    "ssm:PutComplianceItems",
    "ssm:PutConfigurePackageResult",
    "ssm:UpdateAssociationStatus",
    "ssm:UpdateInstanceAssociationStatus",
    "ssm:UpdateInstanceInformation",
    "ssm:GetConnectionStatus",
    "ssm:DescribeInstanceInformation",
    "ssmmessages>CreateControlChannel",
    "ssmmessages>CreateDataChannel",
    "ssmmessages:OpenControlChannel",
    "ssmmessages:OpenDataChannel"
],
"Resource": [
    "*"
]
},
{
    "Sid": "2",
    "Effect": "Allow",
    "Action": [
        "ec2messages:AcknowledgeMessage",
        "ec2messages>DeleteMessage",
        "ec2messages:FailMessage",
        "ec2messages:GetEndpoint",
        "ec2messages:GetMessages",
        "ec2messages:SendReply"
    ],
    "Resource": [
        "*"
    ]
},
{
    "Sid": "3",
    "Effect": "Allow",
    "Action": [
        "logs:PutRetentionPolicy",
        "logs:PutLogEvents",
        "logs:DescribeLogStreams",
        "logs:DescribeLogGroups",
        "logs>CreateLogStream",
        "logs>CreateLogGroup"
    ],
    "Resource": [
        "arn:aws:logs:$REGION*:log-group:rds-custom-instance*"
    ]
},
{
    "Sid": "4",
    "Effect": "Allow",
    "Action": [
        "s3:putObject",
        "s3:getObject",
        "s3:getObjectVersion"
    ],
    "Resource": [
        "arn:aws:s3:::do-not-delete-rds-custom-*/*"
    ]
}
```

```

        },
        {
            "Sid": "5",
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutMetricData"
            ],
            "Resource": [
                "*"
            ],
            "Condition": {
                "StringEquals": {
                    "cloudwatch:namespace": [
                        "RDSCustomForOracle/Agent"
                    ]
                }
            }
        },
        {
            "Sid": "6",
            "Effect": "Allow",
            "Action": [
                "events:PutEvents"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Sid": "7",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue",
                "secretsmanager:DescribeSecret"
            ],
            "Resource": [
                "arn:aws:secretsmanager:'$REGION':'$ACCOUNT_ID':secret:do-not-delete-rds-
custom-*"
            ]
        },
        {
            "Sid": "8",
            "Effect": "Allow",
            "Action": [
                "s3>ListBucketVersions"
            ],
            "Resource": [
                "arn:aws:s3:::do-not-delete-rds-custom-*"
            ]
        },
        {
            "Sid": "9",
            "Effect": "Allow",
            "Action": "ec2>CreateSnapshots",
            "Resource": [
                "arn:aws:ec2:*.*:instance/*",
                "arn:aws:ec2:*.*:volume/*"
            ],
            "Condition": {
                "StringEquals": {
                    "ec2:ResourceTag/AWSRDSCustom": "custom-oracle"
                }
            }
        },
        {
            "Sid": "10",

```

```

        "Effect": "Allow",
        "Action": "ec2:CreateSnapshots",
        "Resource": [
            "arn:aws:ec2:*::snapshot/*"
        ]
    },
    {

        "Effect": "Allow",
        "Action": [
            "kms:Decrypt",
            "kms:GenerateDataKey"
        ],
        "Resource": [
            "arn:aws:kms:'$REGION':'$ACCOUNT_ID':key/abcd1234-5678-eeff-9012-123456abcdef"
        ]
    },
    {
        "Sid": "12",
        "Effect": "Allow",
        "Action": "ec2:CreateTags",
        "Resource": "*",
        "Condition": {
            "StringLike": {
                "ec2:CreateAction": [
                    "CreateSnapshots"
                ]
            }
        }
    }
]
}

```

Create your RDS Custom instance profile

Create your IAM instance profile as follows, naming it `AWSRDSCustomInstanceProfileForRdsCustomInstance`.

```
aws iam create-instance-profile \
--instance-profile-name AWSRDSCustomInstanceProfileForRdsCustomInstance
```

Add `AWSRDSCustomInstanceRoleForRdsCustomInstance` to your RDS Custom instance profile

Add the IAM role `AWSRDSCustomInstanceRoleForRdsCustomInstance` to the profile `AWSRDSCustomInstanceProfileForRdsCustomInstance`.

```
aws iam add-role-to-instance-profile \
--instance-profile-name AWSRDSCustomInstanceProfileForRdsCustomInstance \
--role-name AWSRDSCustomInstanceRoleForRdsCustomInstance
```

Configuring your VPC manually

Your RDS Custom DB instance is in a virtual private cloud (VPC) based on the Amazon VPC service, just like an Amazon EC2 instance or Amazon RDS instance. You provide and configure your own VPC. Thus, you have full control over your instance networking setup.

RDS Custom sends communication from your DB instance to other AWS services. To make sure that RDS Custom can communicate, it validates network connectivity to these services.

Your DB instance communicates with the following AWS services:

- Amazon CloudWatch
- Amazon CloudWatch Logs
- Amazon CloudWatch Events
- Amazon EC2
- Amazon EventBridge
- Amazon S3
- AWS Secrets Manager
- AWS Systems Manager

Make sure that VPC components involved in communication between the DB instance and AWS services are configured with the following requirements:

- The DB instance can make outbound connections on port 443 to other AWS services.
- The VPC allows incoming responses to requests originating from your DB instance.
- Correctly resolve the domain names of endpoints for each AWS service.

If you already configured a VPC for a different RDS Custom engine, you can reuse that VPC and skip this process.

Topics

- [Configure your instance security group \(p. 775\)](#)
- [Configure endpoints for dependent AWS services \(p. 776\)](#)
- [Configure the instance metadata service \(p. 777\)](#)

Configure your instance security group

A *security group* acts as a virtual firewall for a VPC instance, controlling both inbound and outbound traffic. An RDS Custom DB instance has a default security group that protects the instance. Make sure that your security group permits traffic between RDS Custom and other AWS services.

To configure your security group for RDS Custom

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc>.
2. Allow RDS Custom to use the default security group, or create your own security group.

For detailed instructions, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).

3. Make sure that your security group permits outbound connections on port 443. RDS Custom needs this port to communicate with dependent AWS services.
4. If you have a private VPC and use VPC endpoints, make sure that the security group associated with the DB instance allows outbound connections on port 443 to VPC endpoints. Also make sure that the security group associated with the VPC endpoint allows inbound connections on port 443 from the DB instance.

If incoming connections aren't allowed, the RDS Custom instance can't connect to the AWS Systems Manager and Amazon EC2 endpoints. For more information, see [Create a Virtual Private Cloud endpoint](#) in the *AWS Systems Manager User Guide*.

For more information about security groups, see [Security groups for your VPC](#) in the *Amazon VPC Developer Guide*.

Configure endpoints for dependent AWS services

Make sure that your VPC allows outbound traffic to the following AWS services with which the DB instance communicates:

- Amazon CloudWatch
- Amazon CloudWatch Logs
- Amazon CloudWatch Events
- Amazon EC2
- Amazon EventBridge
- Amazon S3
- AWS Secrets Manager
- AWS Systems Manager

We recommend that you add endpoints for every service to your VPC using the following instructions. However, you can use any solution that lets your VPC communicate with AWS service endpoints. For example, you can use Network Address Translation (NAT) or AWS Direct Connect.

To configure endpoints for AWS services with which RDS Custom works

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. On the navigation bar, use the Region selector to choose the AWS Region.
3. In the navigation pane, choose **Endpoints**. In the main pane, choose **Create Endpoint**.
4. For **Service category**, choose **AWS services**.
5. For **Service Name**, choose the endpoint shown in the table.
6. For **VPC**, choose your VPC.
7. For **Subnets**, choose a subnet from each Availability Zone to include.

The VPC endpoint can span multiple Availability Zones. AWS creates an elastic network interface for the VPC endpoint in each subnet that you choose. Each network interface has a Domain Name System (DNS) host name and a private IP address.

8. For **Security group**, choose or create a security group.

You can use security groups to control access to your endpoint, much as you use a firewall. For more information about security groups, see [Security groups for your VPC](#) in the *Amazon VPC User Guide*.

9. Optionally, you can attach a policy to the VPC endpoint. Endpoint policies can control access to the AWS service to which you are connecting. The default policy allows all requests to pass through the endpoint. If you're using a custom policy, make sure that requests from the DB instance are allowed in the policy.
10. Choose **Create endpoint**.

The following table explains how to find the list of endpoints that your VPC needs for outbound communications.

Service	Endpoint format	Notes and links
AWS Systems Manager	Use the following endpoint formats: <ul style="list-style-type: none">• <code>ssm.region.amazonaws.com</code>• <code>ssmmessages.region.amazonaws.com</code>	For the list of endpoints in each Region, see AWS Systems Manager endpoints and quotas in the <i>Amazon Web Services General Reference</i> .

Service	Endpoint format	Notes and links
AWS Secrets Manager	Use the endpoint format <code>secretsmanager.region.amazonaws.com</code> .	For the list of endpoints in each Region, see AWS Secrets Manager endpoints and quotas in the <i>Amazon Web Services General Reference</i> .
Amazon CloudWatch	Use the following endpoint formats: <ul style="list-style-type: none"> For CloudWatch metrics, use <code>monitoring.region.amazonaws.com</code> For CloudWatch Events, use <code>events.region.amazonaws.com</code> For CloudWatch Logs, use <code>logs.region.amazonaws.com</code> 	For the list of endpoints in every Region, see: <ul style="list-style-type: none"> Amazon CloudWatch endpoints and quotas in the <i>Amazon Web Services General Reference</i> Amazon CloudWatch Logs endpoints and quotas in the <i>Amazon Web Services General Reference</i> Amazon CloudWatch Events endpoints and quotas in the <i>Amazon Web Services General Reference</i>
Amazon EC2	Use the following endpoint formats: <ul style="list-style-type: none"> <code>ec2.region.amazonaws.com</code> <code>ec2messages.region.amazonaws.com</code> 	For the list of endpoints in each Region, see Amazon Elastic Compute Cloud endpoints and quotas in the <i>Amazon Web Services General Reference</i> .
Amazon S3	Use the endpoint format <code>s3.region.amazonaws.com</code> .	For the list of endpoints in each Region, see Amazon Simple Storage Service endpoints and quotas in the <i>Amazon Web Services General Reference</i> . <p>To learn more about gateway endpoints for Amazon S3, see Endpoints for Amazon S3 in the <i>Amazon VPC Developer Guide</i>.</p> <p>To learn how to create an access point, see Creating access points in the <i>Amazon VPC Developer Guide</i>.</p> <p>To learn how to create a gateway endpoints for Amazon S3, see Gateway VPC endpoints.</p>

Configure the instance metadata service

Make sure that your instance can do the following:

- Access the instance metadata service using Instance Metadata Service Version 2 (IMDSv2).
- Allow outbound communications through port 80 (HTTP) to the IMDS link IP address.
- Request instance metadata from `http://169.254.169.254`, the IMDSv2 link.

For more information, see [Use IMDSv2](#) in the *Amazon EC2 User Guide for Linux Instances*.

RDS Custom for Oracle automation uses IMDSv2 by default, by setting `HttpTokens=enabled` on the underlying Amazon EC2 instance. However, you can use IMDSv1 if you want. For more information, see [Configure the instance metadata options](#) in the *Amazon EC2 User Guide for Linux Instances*.

Grant required permissions to your IAM user

Make sure that the IAM principal that creates the CEV or DB instance has either of the following policies:

- The `AdministratorAccess` policy
- The `AmazonRDSFullAccess` policy with required permissions for Amazon S3 and AWS KMS (required for both CEV and DB creation), CEV creation, and DB instance creation.

Topics

- [Permissions required for Amazon S3 and AWS KMS \(p. 778\)](#)
- [Permissions required for creating a CEV \(p. 778\)](#)
- [Permissions required for creating a DB instance from a CEV \(p. 779\)](#)

Permissions required for Amazon S3 and AWS KMS

To create CEVs or RDS Custom for Oracle DB instances, the IAM principal needs to access Amazon S3 and AWS KMS. The following sample JSON policy grants the required permissions.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "CreateS3Bucket",  
            "Effect": "Allow",  
            "Action": [  
                "s3:CreateBucket",  
                "s3:PutBucketPolicy",  
                "s3:PutBucketObjectLockConfiguration",  
                "s3:PutBucketVersioning"  
            ],  
            "Resource": "arn:aws:s3:::do-not-delete-rds-custom-*"  
        },  
        {  
            "Sid": "CreateKmsGrant",  
            "Effect": "Allow",  
            "Action": "kms>CreateGrant",  
            "Resource": "*"  
        }  
    ]  
}
```

For more information about the `kms>CreateGrant` permission, see [AWS KMS key management \(p. 2004\)](#).

Permissions required for creating a CEV

To create a CEV, the IAM principal needs the following additional permissions:

```
s3:GetObjectAcl  
s3:GetObject  
s3:GetObjectTagging  
s3>ListBucket  
mediaimport>CreateDatabaseBinarySnapshot
```

The following sample JSON policy grants the additional permissions to bucket `my-custom-installation-files` and its contents.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AccessToS3MediaBucket",
            "Effect": "Allow",
            "Action": [
                "s3:GetObjectAcl",
                "s3:GetObject",
                "s3:GetObjectTagging",
                "s3>ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::my-custom-installation-files",
                "arn:aws:s3:::my-custom-installation-files/*"
            ]
        },
        {
            "Sid": "PermissionForByom",
            "Effect": "Allow",
            "Action": [
                "mediaimport>CreateDatabaseBinarySnapshot"
            ],
            "Resource": "*"
        }
    ]
}
```

You can grant similar permissions for Amazon S3 to caller accounts using an S3 bucket policy.

Permissions required for creating a DB instance from a CEV

To create a DB instance from an existing CEV, the IAM principal needs the following additional permissions:

```
iam:SimulatePrincipalPolicy
cloudtrail>CreateTrail
cloudtrail:StartLogging
```

The following sample JSON policy grants the required permissions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ValidateIamRole",
            "Effect": "Allow",
            "Action": "iam:SimulatePrincipalPolicy",
            "Resource": "*"
        },
        {
            "Sid": "CreateCloudTrail",
            "Effect": "Allow",
            "Action": [
                "cloudtrail>CreateTrail",
                "cloudtrail:StartLogging"
            ],
            "Resource": "arn:aws:cloudtrail:*:*:trail/do-not-delete-rds-custom-*"
        }
    ]
}
```

Working with custom engine versions for Amazon RDS Custom for Oracle

A *custom engine version (CEV)* for Amazon RDS Custom for Oracle is a binary volume snapshot of a database engine and specific Amazon Machine Image (AMI). You store your database installation files in Amazon S3. RDS Custom uses the installation files to create your CEV for you.

Topics

- [Creating a CEV \(p. 798\)](#)
- [Modifying CEV status \(p. 801\)](#)
- [Viewing CEV details \(p. 803\)](#)
- [Deleting a CEV \(p. 805\)](#)

Preparing to create a CEV

To create a CEV, access the installation files and patches that are stored in your Amazon S3 bucket for any of the following releases:

- Oracle Database 19c
- Oracle Database 18c
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1)

For example, you can use the April 2021 RU/RUR for Oracle Database 19c, or any valid combination of installation files and patches.

Downloading your database installation files and patches from Oracle Software Delivery Cloud

The Oracle Database installation files and patches are hosted on Oracle Software Delivery Cloud.

To download the database installation files for Oracle Database 19c

1. Go to <https://edelivery.oracle.com/> and sign in.
2. In the box, enter **Oracle Database Enterprise Edition** and choose **Search**.
3. Choose **DLP: Oracle Database Enterprise Edition 19.3.0.0.0 (Oracle Database Enterprise Edition)**.
4. Choose **Continue**.
5. Clear the **Download Queue** check box.
6. Choose **Oracle Database 19.3.0.0.0 - Long Term Release**.

7. Choose **Linux x86-64** in **Platform/Languages**.
8. Choose **Continue**, and then sign the waiver.
9. Choose **V982063-01.zip**, choose **Download**, and then save the file.

Note

The SHA-256 hash is
BA8329C757133DA313ED3B6D7F86C5AC42CD9970A28BF2E6233F3235233AA8D8.

10. Click the links in the following table to download the Oracle patches. All URLs are for updates.oracle.com or support.oracle.com.

Uploading your installation files to Amazon S3

Upload your Oracle installation and patch files to Amazon S3 using the AWS CLI. The S3 bucket that contains your installation files must be in the same AWS Region as your CEV.

Choose either of the following options:

- Use `aws s3 cp` to upload a single .zip file.
Upload each installation .zip file separately. Don't combine the .zip files into a single .zip file.
- Use `aws s3 sync` to upload a directory.

List your installation files using either the AWS Management Console or the AWS CLI.

Examples in this section use the following placeholders:

- ***install-or-patch-file.zip*** – Oracle installation media file. For example, p32126828_190000_Linux-x86-64.zip is a patch.
- ***my-custom-installation-files*** – Your Amazon S3 bucket designated for your uploaded installation files.
- ***123456789012/cev1*** – An optional prefix in your Amazon S3 bucket.
- ***source-bucket*** – An Amazon S3 bucket where you can optionally stage files.

The following example uploads ***install-or-patch-file.zip*** to the ***123456789012/cev1*** folder in the RDS Custom Amazon S3 bucket. Run a separate `aws s3` command for each .zip that you want to upload.

For Linux, macOS, or Unix:

```
aws s3 cp install-or-patch-file.zip \  
s3://my-custom-installation-files/123456789012/cev1/
```

For Windows:

```
aws s3 cp install-or-patch-file.zip ^  
s3://my-custom-installation-files/123456789012/cev1/
```

Verify that your S3 bucket is in the AWS Region where you plan to run the `create-custom-db-engine-version` command.

```
aws s3api get-bucket-location --bucket my-custom-installation-files
```

List the files in your RDS Custom Amazon S3 bucket as follows.

```
aws s3 ls \  
s3://my-custom-installation-files/123456789012/cev1/
```

The following example uploads the files in your local `cev1` folder to the `123456789012/cev1` folder in your Amazon S3 bucket.

For Linux, macOS, or Unix:

```
aws s3 sync cev1 \  
s3://my-custom-installation-files/123456789012/cev1/
```

For Windows:

```
aws s3 sync cev1 ^  
s3://my-custom-installation-files/123456789012/cev1/
```

The following example uploads all files in `source-bucket` to the `123456789012/cev1` folder in your Amazon S3 bucket.

For Linux, macOS, or Unix:

```
aws s3 sync s3://source-bucket/ \  
s3://my-custom-installation-files/123456789012/cev1/
```

For Windows:

```
aws s3 sync s3://source-bucket/ ^  
s3://my-custom-installation-files/123456789012/cev1/
```

Sharing your installation media in S3 across AWS accounts

For the purposes of this section, the Amazon S3 bucket that contains your uploaded Oracle installation files is your *media bucket*. Your organization might use multiple AWS accounts in an AWS Region. If so, you might want to use one AWS account to populate your media bucket and a different AWS account to create CEVs. If you don't intend to share your media bucket, skip to the next section.

This section assumes the following:

- You can access the account that created your media bucket and a different account in which you intend to create CEVs.

- You intend to create CEVs in only one AWS Region. If you intend to use multiple Regions, create a media bucket in each Region.
- You're using the CLI. If you're using the Amazon S3 console, adapt the following steps.

To configure your media bucket for sharing across AWS accounts

1. Log in to the AWS account that contains the S3 bucket into which you uploaded your installation media.
2. Start with either a blank JSON policy template or an existing policy that you can adapt.

The following command retrieves an existing policy and saves it as *my-policy.json*. In this example, the S3 bucket containing your installation files is named *oracle-media-bucket*.

```
aws s3api get-bucket-policy \
--bucket oracle-media-bucket \
--query Policy \
--output text > my-policy.json
```

3. Edit the media bucket permissions as follows:

- In the Resource element of your template, specify the S3 bucket into which you uploaded your Oracle Database installation files.
- In the Principal element, specify the ARNs for all AWS accounts that you intend to use to create CEVs. You can add the root, a user, or a role to the S3 bucket allow list. For more information, see [IAM identifiers](#) in the *AWS Identity and Access Management User Guide*.

                "arn:aws:s3:::oracle-media-bucket",
                "arn:aws:s3:::oracle-media-bucket/*"
            ]
        }
    ]
}
```

4. Attach the policy to your media bucket.

In the following example, *oracle-media-bucket* is the name of the S3 bucket that contains your installation files, and *my-policy.json* is the name of your JSON file.

```
aws s3api put-bucket-policy \
--bucket oracle-media-bucket \
--policy file://my-policy.json
```

5. Log in to an AWS account in which you intend to create CEVs.
6. Verify that this account can access the media bucket in the AWS account that created it.

```
aws s3 ls --query "Buckets[] .Name"
```

For more information, see [aws s3 ls](#) in the *AWS CLI Command Reference*.

7. Create a CEV by following the steps in [Creating a CEV \(p. 798\)](#).

Preparing the CEV manifest

A *CEV manifest* is a JSON document that includes the following:

- (Required) The list of installation .zip files that you uploaded to Amazon S3. RDS Custom applies the patches in the order in which they're listed in the manifest.
- (Optional) Installation parameters that set nondefault values for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. Be aware that you can't modify the installation parameters for an existing CEV or an existing DB instance. You also can't upgrade from one CEV to another CEV when the installation parameters have different settings.

For sample CEV manifests, see [CEV manifest examples \(p. 795\)](#).

Topics

- [JSON fields in the CEV manifest \(p. 789\)](#)
- [Creating the CEV manifest \(p. 795\)](#)
- [CEV manifest examples \(p. 795\)](#)

JSON fields in the CEV manifest

The following table describes the JSON fields in the manifest.

JSON fields in the CEV manifest

JSON field	Description
MediaImportTemplateVersion	Version of the CEV manifest. The date is in the format YYYY-MM-DD.
databaseInstallationFileName	Ordered list of installation files for the database.
opatchFileNames	Ordered list of OPatch installers used for the Oracle DB engine. Only one value is valid. Values for opatchFileNames must start with p6880880_.
psuRuPatchFileNames	The PSU and RU patches for this database. Important If you include psuRuPatchFileNames, opatchFileNames is required. Values for opatchFileNames must start with p6880880_. The PSU and RU patches for this database.
OtherPatchFileNames	The patches that aren't in the list of PSU and RU patches. RDS Custom applies these patches after applying the PSU and RU patches.

JSON field	Description
	<p>Important If you include OtherPatchFileNames, opatchFileNames is required. Values for opatchFileNames must start with p6880880_.</p>

JSON field	Description
installationParameters	<p>Nondefault settings for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. You can set the following parameters:</p> <p>oracleBase</p> <p>The directory under which your Oracle binaries are installed. It is the mount point of the binary volume that stores your files. The Oracle base directory can include multiple Oracle homes. For example, if /home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1 is one of your Oracle home directories, then /home/oracle is the Oracle base directory. A user-specified Oracle base directory is not a symbolic link.</p> <p>If you don't specify the Oracle base, the default directory is /rdsdbbin.</p> <p>oracleHome</p> <p>The directory in which your Oracle database binaries are installed. For example, if you specify /home/oracle/ as your Oracle base, then you might specify /home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1/ as your Oracle home. A user-specified Oracle home directory is not a symbolic link. The Oracle home value is referenced by the \$ORACLE_HOME environment variable.</p> <p>If you don't specify the Oracle home, the default naming format is /rdsdbbin/oracle.<i>major-engine-version</i>.custom.r1.<i>engine-edition</i>.1.</p> <p>unixUsername</p> <p>The name of the UNIX user that owns the Oracle software. RDS Custom assumes this user when running local database commands. If you specify both unixUid and unixUsername, RDS Custom creates the user if it doesn't exist, and then assigns the UID to the user if it's not the same as the initial UID.</p> <p>The default user name is rdsdb.</p> <p>unixUserId</p> <p>The ID (UID) of the UNIX user that owns the Oracle software. If you specify both unixUid and unixUsername, RDS Custom creates the user if it doesn't exist, and then assigns the UID to the user if it's not the same as the initial UID.</p> <p>The default UID is 61001. This is the UID of the user rdsdb.</p> <p>unixGroupName</p> <p>The name of the UNIX group. The UNIX user that owns the Oracle software belongs to this group.</p> <p>The default group name is rdsdb.</p> <p>unixGroupId</p> <p>The ID of the UNIX group to which the UNIX user belongs.</p> <p>The default group ID is 1000. This is the ID of the group rdsdb.</p>

Each Oracle Database release has a different list of supported installation files. When you create your CEV manifest, make sure to specify only files that are supported by RDS Custom for Oracle. Otherwise, CEV creation fails with an error.

The following table shows valid values for Oracle Database 12c Release 1 (12.1).

Creating the CEV manifest

To create a CEV manifest

1. List all installation files that you plan to apply, in the order that you want to apply them.
2. Correlate the installation files with the JSON fields described in [JSON fields in the CEV manifest \(p. 789\)](#).
3. Do either of the following:
 - Create the CEV manifest as a JSON text file.
 - Edit the CEV manifest template when you create the CEV in the console. For more information, see [Creating a CEV \(p. 798\)](#).

CEV manifest examples

The following examples show CEV manifest files for different Oracle Database releases. If you include a JSON field in your manifest, make sure that it isn't empty. For example, the following CEV manifest isn't valid because otherPatchFileNames is empty.

```
{  
    "mediaImportTemplateVersion": "2020-08-14",  
    "databaseInstallationFileNames": [  
        "V982063-01.zip"  
    ],  
    "opatchFileNames": [  
        "p6880880_190000_Linux-x86-64.zip"  
    ],  
    "psuRuPatchFileNames": [  
        "p32126828_190000_Linux-x86-64.zip"  
    ],  
    "otherPatchFileNames": [  
    ]  
}
```

Example Sample CEV manifest for Oracle Database 12c Release 1 (12.1)

In the following example for the July 2021 PSU for Oracle Database 12c Release 1 (12.1), RDS Custom applies the patches in the order specified. Thus, RDS Custom applies p32768233, then p32876425, then p18759211, and so on. The example sets new values for the UNIX user and group, and the Oracle home and Oracle base.

        "p29997937_180000_Linux-x86-64.zip",
        "p31335037_180000_Linux-x86-64.zip",
        "p31335142_180000_Generic.zip"
    ],
    "installationParameters": {
        "unixGroupName": "dba",
        "unixUname": "oracle",
        "oracleHome": "/home/oracle/18.0.0.0.ru-2020-10.rur-2020-10.r1",
        "oracleBase": "/home/oracle/"
    }
}

```

Example Sample CEV manifest for Oracle Database 19c

In the following example for Oracle Database 19c, RDS Custom applies p32126828, then p29213893, then p29782284, and so on. The example sets new values for the UNIX user and group, and the Oracle home and Oracle base.

```
{
    "mediaImportTemplateVersion": "2020-08-14",
```

```
"databaseInstallationFileNames": [
    "V982063-01.zip"
],
"opatchFileNames": [
    "p6880880_190000_Linux-x86-64.zip"
],
"psuRuPatchFileNames": [
    "p32126828_190000_Linux-x86-64.zip"
],
"otherPatchFileNames": [
    "p29213893_1910000DBRU_Generic.zip",
    "p29782284_1910000DBRU_Generic.zip",
    "p28730253_190000_Linux-x86-64.zip",
    "p29374604_1910000DBRU_Linux-x86-64.zip",
    "p28852325_190000_Linux-x86-64.zip",
    "p29997937_190000_Linux-x86-64.zip",
    "p31335037_190000_Linux-x86-64.zip",
    "p31335142_190000_Generic.zip"
],
"installationParameters": {
    "unixGroupName": "dba",
    "unixUname": "oracle",
    "oracleHome": "/home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1",
    "oracleBase": "/home/oracle"
}
}
```

Validating the CEV manifest

Optionally, verify that manifest is a valid JSON file by running the `json.tool` Python script.

For example, if you change into the directory containing a CEV manifest named `manifest.json`, run the following command.

```
python -m json.tool < manifest.json
```

Adding necessary IAM permissions

Make sure that the IAM principal that creates the CEV has the necessary policies described in [Grant required permissions to your IAM user \(p. 778\)](#).

Creating a CEV

You can create a CEV using the AWS Management Console or the AWS CLI. Typically, creating a CEV takes about two hours.

You can then use the CEV to create an RDS Custom instance. Make sure that the Amazon S3 bucket containing your installation files is in the same AWS Region as your CEV. Otherwise, the process to create a CEV fails.

For more information, see [Creating an RDS Custom for Oracle DB instance \(p. 808\)](#).

Console

To create a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Custom engine versions**.

The **Custom engine versions** page shows all CEVs that currently exist. If you haven't created any CEVs, the page is empty.

3. Choose **Create custom engine version**.
4. For **Engine type**, choose **Oracle**.
5. For **Edition**, choose **Oracle Enterprise Edition**. **Oracle Enterprise Edition (Oracle RAC option)** isn't supported.
6. For **Architecture settings**, choose **Multitenant architecture** to create a Multitenant CEV, which uses the engine `custom-oracle-ee-cdb`. You can create an RDS Custom for Oracle CDB with a Multitenant CEV only. If you don't choose this option, your CEV is a non-CDB, which uses the engine `custom-oracle-ee`.
7. For **Major version**, choose the major engine version.
8. In **Version details**, enter a valid name in **Custom engine version name**.

The name format is `major-engine-version.customized_string`. You can use 1–50 alphanumeric characters, underscores, dashes, and periods. For example, you might enter the name **19.cdb_cev1**.

Optionally, enter a description for your CEV.

9. For **S3 location of manifest files**, enter the location of the Amazon S3 bucket that you specified in [Uploading your installation files to Amazon S3 \(p. 786\)](#). For example, enter `s3://my-custom-installation-files/806242271698/cev1/`.
10. In the **RDS Custom encryption** section, select **Enter a key ARN** to list the available AWS KMS keys.

Then select your KMS key from the list. An AWS KMS key is required for RDS Custom. For more information, see [Make sure that you have a symmetric encryption AWS KMS key \(p. 768\)](#).

11. Choose **Create custom engine version**.

If the CEV manifest has an invalid form, the console displays **Error validating the CEV manifest**. Fix the problems, and try again.

The **Custom engine versions** page appears. Your CEV is shown with the status **Creating**. The process to create the CEV takes approximately two hours.

AWS CLI

To create a CEV by using the AWS CLI, run the `create-custom-db-engine-version` command.

The following options are required:

- `--engine engine-type`, where `engine-type` is either `custom-oracle-ee-cdb` for a CDB or `custom-oracle-ee` for a non-CDB. You can create CDBs only from a CEV created with `custom-oracle-ee-cdb`. You can create non-CDBs only from a CEV created with `custom-oracle-ee`.
- `--engine-version major-engine-version.customized_string`
- `--kms-key-id`
- `--manifest manifest_string` or `--manifest file:file_name`

Newline characters aren't permitted in `manifest_string`. Make sure to escape double quotes ("") in the JSON code by prefixing them with a backslash (\).

The following example shows the `manifest_string` for 19c from [Preparing the CEV manifest \(p. 789\)](#). The example sets new values for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. If you copy this string, remove all newline characters before pasting it into your command.

```
"{\"mediaImportTemplateVersion\": \"2020-08-14\",
\"databaseInstallationFileNames\": [\"V982063-01.zip\"],
\"opatchFileNames\": [\"p6880880_190000_Linux-x86-64.zip\"],
\"psuRuPatchFileNames\": [\"p32126828_190000_Linux-x86-64.zip\"],
\"otherPatchFileNames\": [\"p29213893_1910000DBRU_Generic.zip\",
\"p29782284_1910000DBRU_Generic.zip\", \"p28730253_190000_Linux-x86-64.zip\",
\"p29374604_1910000DBRU_Linux-x86-64.zip\", \"p28852325_190000_Linux-
x86-64.zip\", \"p29997937_190000_Linux-x86-64.zip\", \"p31335037_190000_Linux-
x86-64.zip\", \"p31335142_190000_Generic.zip\"]}\"installationParameters\":
{ \"unixGroupName\":\"dba\", \\"unixUname\":\"oracle\", \\"oracleHome\":\"/\"/
home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1\", \\"oracleBase
\":\"/home/oracle/\\"}}}"
• --database-installation-files-s3-bucket-name s3-bucket-name, where s3-
bucket-name is the bucket name that you specified in Uploading your installation files to Amazon S3 \(p. 786\). The AWS Region in which you run create-custom-db-engine-version must be the same Region as your Amazon S3 bucket.
```

You can also specify the following options:

- `--description my-cev-description`
- `database-installation-files-s3-prefix prefix`, where *prefix* is the folder name that you specified in [Uploading your installation files to Amazon S3 \(p. 786\)](#).

The following example creates a Multitenant CEV named `19.cdb_cev1`. Make sure that the name of your CEV starts with the major engine version number.

Example

For Linux, macOS, or Unix:

```
aws rds create-custom-db-engine-version \
--engine custom-oracle-ee-cdb \
--engine-version 19.cdb_cev1 \
--database-installation-files-s3-bucket-name my-custom-installation-files \
--database-installation-files-s3-prefix 123456789012/cev1 \
--kms-key-id my-kms-key \
--description "some text" \
--manifest manifest_string
```

For Windows:

```
aws rds create-custom-db-engine-version ^
--engine custom-oracle-ee-cdb ^
--engine-version 19.cdb_cev1 ^
--database-installation-files-s3-bucket-name s3://my-custom-installation-files ^
--database-installation-files-s3-prefix 123456789012/cev1 ^
--kms-key-id my-kms-key ^
--description "some text" ^
--manifest manifest_string
```

Example

Get details about your CEV by using the `describe-db-engine-versions` command.

```
aws rds describe-db-engine-versions \
```

```
--engine custom-oracle-ee-cdb \
--include-all
```

The following partial sample output shows the engine, parameter groups, manifest, and other information.

```

```

Failure to create a CEV

If the process to create a CEV fails, RDS Custom issues RDS-EVENT-0198 with the message **Creation failed for custom engine version *major-engine-version.cev_name***, and includes details about the failure. For example, the event prints missing files.

You can't modify a failed CEV. You can only delete it, then try again to create a CEV after fixing the causes of the failure. For information about troubleshooting the reasons for CEV creation failure, see [Troubleshooting custom engine version creation for RDS Custom for Oracle \(p. 890\)](#).

Modifying CEV status

You can modify a CEV using the AWS Management Console or the AWS CLI. You can modify the CEV description or its availability status. Your CEV has one of the following status values:

- **available** – You can use this CEV to create a new RDS Custom DB instance or upgrade a DB instance. This is the default status for a newly created CEV.
- **inactive** – You can't create or upgrade an RDS Custom instance with this CEV. You can't restore a DB snapshot to create a new RDS Custom DB instance with this CEV.

You can change the CEV from any supported status to any other supported status. You might change status to prevent the accidental use of a CEV or make a discontinued CEV eligible for use again. For example, you might change the status of your CEV from available to inactive, and from inactive back to available.

Console

To modify a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Custom engine versions**.
3. Choose a CEV whose description or status you want to modify.
4. For **Actions**, choose **Modify**.
5. Make any of the following changes:
 - For **CEV status settings**, choose a new availability status.
 - For **Version description**, enter a new description.
6. Choose **Modify CEV**.

If the CEV is in use, the console displays **You can't modify the CEV status**. Fix the problems, and try again.

The **Custom engine versions** page appears.

AWS CLI

To modify a CEV by using the AWS CLI, run the `modify-custom-db-engine-version` command. You can find CEVs to modify by running the `describe-db-engine-versions` command.

The following options are required:

- `--engine custom-oracle-ee`
- `--engine-version cev`, where *cev* is the name of the custom engine version that you want to modify
- `--status status`, where *status* is the availability status that you want to assign to the CEV

The following example changes a CEV named `19.my_cev1` from its current status to `inactive`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-custom-db-engine-version \
    --engine custom-oracle-ee \
    --engine-version 19.my_cev1 \
    --status inactive
```

For Windows:

```
aws rds modify-custom-db-engine-version ^
    --engine custom-oracle-ee ^
    --engine-version 19.my_cev1 ^
    --status inactive
```

Viewing CEV details

You can view details about your CEV manifest and the command used to create your CEV by using the AWS Management Console or the AWS CLI.

Console

To view CEV details

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Custom engine versions**.

The **Custom engine versions** page shows all CEVs that currently exist. If you haven't created any CEVs, the page is empty.

3. Choose the name of the CEV that you want to view.
4. Choose **Configuration** to view the installation parameters specified in your manifest.

Configuration	Databases	Snapshots	Manifest
Configuration			
<p>Edition Oracle Enterprise Edition</p> <p>Major Version 19</p> <p>Installation files location s3://.../V982063-01.zip</p>	<p>Amazon Resource Name (ARN) arn:aws:rds:us-west-2: .../rdsdbbin/oracle.19.custom.r1.EE.1</p> <p>KMS key ID .../p30528704_197000DBRU_Linux-x86-64.zip</p>	<p>DB installation parameters</p> <p>Oracle Base Directory /rdsdbbin</p> <p>Oracle Home Directory /rdsdbbin/oracle.19.custom.r1.EE.1</p> <p>Oracle User Name rdsdb</p> <p>Oracle UID 61001</p> <p>Oracle Group Name rdsdb</p> <p>Oracle GID 1000</p>	

5. Choose **Manifest** to view the installation parameters specified in the --manifest option of the create-custom-db-engine-version command. You can copy this text, replace values as needed, and use them in a new command.

Configuration	Databases	Snapshots	Automated Backups	Tags	Manifest
CEV manifest					
<pre>--manifest "{\"databaseInstallationFileNames\": [\"V982063-01.zip\"], \"mediaImportTemplateVersion\": \"2020-08-14\", \"opatchFileNames\":\n[\"p6880880_190000_1220119_Linux-x86-64.zip\"], \"psuRuPatchFileNames\": [\"p30783543_190000_Linux-x86-64.zip\", \"p30528704_197000DBRU_Linux-\nx86-64.zip\", \"p29213893_197000DBRU_Generic.zip\", \"p28730253_190000_Linux-x86-64.zip\"], \"p28852325_190000_Linux-x86-\n64.zip\", \"p29997937_190000_Linux-x86-64.zip\", \"p29997959_190000_Generic.zip\"], \"installationParameters\":\n{\"oracleHome\": \"/rdsdbbin/oracle.19.custom.r1.EE.1\", \"oracleBase\": \"/rdsdbbin\", \"unixUid\": 61001, \"unixUsername\": \"rdsdb\", \"unixGroupId\": 1000, \"unixGroup\nname\": \"rdsdb\"}}"</pre>					

AWS CLI

To view details about a CEV by using the AWS CLI, run the [describe-db-engine-versions](#) command.

The following options are required:

- `--engine custom-oracle-ee`
- `--engine-version major-engine-version.customized_string`

The following example creates a CEV named `19.my_cev1`. Make sure that the name of your CEV starts with the major engine version number.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine custom-oracle-ee \
--engine-version 19.my_cev1
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine custom-oracle-ee ^
--engine-version 19.my_cev1
```

The following partial sample output shows the engine, parameter groups, manifest, and other information.

```
"DBEngineVersions": [
  {
    "Engine": "custom-oracle-ee",
    "MajorEngineVersion": "19",
    "EngineVersion": "19.my_cev1",
    "DatabaseInstallationFilesS3BucketName": "us-east-1-123456789012-cev-customer-
installation-files",
    "DatabaseInstallationFilesS3Prefix": "123456789012/cev1",
    "CustomDBEngineVersionManifest": "{\n\"mediaImportTemplateVersion\": \"2020-08-14\", \n\"databaseInstallationFileNames\": [\n\"V982063-01.zip\\n\"], \n\"installationParameters\": {\n\"oracleBase\": \"/tmp\", \n\"oracleHome\": \"/tmp/Oracle\\n\"}, \n\"opatchFileNames\": [\n\"p6880880_190000_Linux-x86-64.zip\\n\"], \n\"psuRuPatchFileNames\": [\n\"p32126828_190000_Linux-x86-64.zip\\n\"], \n\"otherPatchFileNames\": [\n\"p29213893_1910000DBRU_Generic.zip\", \n\"p29782284_1910000DBRU_Generic.zip\\n\", \n\"p28730253_190000_Linux-x86-64.zip\\n\", \n\"p29374604_1910000DBRU_Linux-x86-64.zip\\n\", \n\"p28852325_190000_Linux-x86-64.zip\\n\", \n\"p29997937_190000_Linux-x86-64.zip\\n\", \n\"p31335037_190000_Linux-x86-64.zip\\n\", \n\"p31335142_190000_Generic.zip\\n]\\n} \\n",

    "ValidUpgradeTarget": [
      {
        "Engine": "custom-oracle-ee",
        "EngineVersion": "19.cev.2021-01.09",
        "Description": "test",
        "AutoUpgrade": false,
      }
    ]
  }
]
```

```
        "IsMajorVersionUpgrade": false
    }
```

Deleting a CEV

You can delete a CEV using the AWS Management Console or the AWS CLI. Typically, deletion takes a few minutes.

To delete a CEV, it can't be in use by any of the following:

- An RDS Custom DB instance
- A snapshot of an RDS Custom DB instance
- An automated backup of your RDS Custom DB instance

Console

To delete a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Custom engine versions**.
3. Choose a CEV whose description or status you want to delete.
4. For **Actions**, choose **Delete**.

The **Delete *cev_name*?** dialog box appears.

5. Enter **delete me**, and then choose **Delete**.

In the **Custom engine versions** page, the banner shows that your CEV is being deleted.

AWS CLI

To delete a CEV by using the AWS CLI, run the `delete-custom-db-engine-version` command.

The following options are required:

- `--engine custom-oracle-ee`
- `--engine-version cev`, where *cev* is the name of the custom engine version to be deleted

The following example deletes a CEV named `19.my_cev1`.

Example

For Linux, macOS, or Unix:

```
aws rds delete-custom-db-engine-version \
--engine custom-oracle-ee \
--engine-version 19.my_cev1
```

For Windows:

```
aws rds delete-custom-db-engine-version ^
--engine custom-oracle-ee ^
--engine-version 19.my_cev1
```

Configuring a DB instance for Amazon RDS Custom for Oracle

You can create an RDS Custom DB instance, and then connect to it using Secure Shell (SSH) or AWS Systems Manager.

Topics

- [Overview of Amazon RDS Custom for Oracle architecture \(p. 807\)](#)
- [Creating an RDS Custom for Oracle DB instance \(p. 808\)](#)
- [RDS Custom service-linked role \(p. 812\)](#)
- [Connecting to your RDS Custom DB instance using SSH \(p. 812\)](#)
- [Connecting to your RDS Custom DB instance using AWS Systems Manager \(p. 814\)](#)

Overview of Amazon RDS Custom for Oracle architecture

If you create an Amazon RDS Custom for Oracle DB instance with the Oracle Multitenant architecture (custom-oracle-ee-cdb engine type), your database is a container database (CDB). If you don't specify the Oracle Multitenant architecture, your database is a traditional non-CDB that uses the custom-oracle-ee engine type. A non-CDB can't contain pluggable databases (PDBs).

An RDS Custom for Oracle CDB supports the following features:

- Backups
- Restoring and point-time-restore (PITR) from backups
- Read replicas
- Minor version upgrades

When you create a CDB instance using the Oracle Multitenant architecture, your CDB includes the following:

- CDB root (CDB\$ROOT)
- PDB seed (PDB\$SEED)
- PDB

By default, your CDB is named RDSCDB, which is also the name of the Oracle System ID (Oracle SID), and your PDB is named ORCL. You can choose a different name for your PDB, but the Oracle SID and the PDB name can't be the same.

If you want additional PDBs, create them manually using Oracle SQL. RDS Custom for Oracle doesn't restrict the number of PDBs that you can create using Oracle SQL. RDS Custom for Oracle doesn't supply APIs for PDBs. In general, you are responsible for creating and managing PDBs, as in an on-premises deployment.

Note

If you create a PDB, we recommend that you take a manual snapshot afterward in case you need to perform point-in-time recovery (PITR).

You can't rename existing PDBs using Amazon RDS APIs. You also can't rename the CDB using the `modify-db-instance` command.

The open mode for the CDB root is READ WRITE on the primary and MOUNTED on a mounted standby database. RDS Custom for Oracle attempts to open all PDBs when opening the CDB. If RDS Custom for Oracle can't open all PDBs, it issues the event tenant database shutdown.

Creating an RDS Custom for Oracle DB instance

Create an Amazon RDS Custom for Oracle DB instance using either the AWS Management Console or the AWS CLI. The procedure is similar to the procedure for creating an Amazon RDS DB instance. For more information, see [Creating an Amazon RDS DB instance \(p. 230\)](#).

If you included installation parameters in your CEV manifest, then your DB instance uses the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group that you specified. The `oratab` file, which is created by Oracle Database during installation, points to the real installation location rather than to a symbolic link. When RDS Custom runs commands, it runs as the configured OS user rather than the default user `rdsdb`. For more information, see [Preparing the CEV manifest \(p. 789\)](#).

Before you attempt to create or connect to an RDS Custom DB instance, complete the tasks in [Setting up your environment for Amazon RDS Custom for Oracle \(p. 768\)](#).

Console

To create an RDS Custom for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose **Create database**.
4. In **Choose a database creation method**, select **Standard create**.
5. In **Engine options**, choose **Oracle** for the DB engine type. Oracle Database is the only supported DB engine.
6. For **Database management type**, choose **Amazon RDS Custom**.
7. For **Edition**, choose **Oracle Enterprise Edition**.
8. For **Architecture settings**, choose **Multitenant architecture** if you want your database to be a CDB. At creation, your CDB contains one PDB and one PDB seed. If you don't choose **Multitenant architecture**, your database is a non-CDB, which means it can't contain PDBs.
9. For **Database version**, choose the RDS Custom custom engine version (CEV) that you previously created. The CEV has the following format: *major-engine-version*.*customized_string*. An example identifier is 19.cdb_cev1.

If you chose **Multitenant architecture** in the previous step, you can only specify a Multitenant CEV. The console filters out CEVs that were created as non-CDBs.

10. In **Templates**, choose **Production**.
11. In **Settings**, enter a unique name for the **DB instance identifier**.
12. Enter your master password by doing the following:
 - a. In the **Settings** section, open **Credential Settings**.
 - b. Clear the **Auto generate a password** check box.
 - c. Change the **Master username** value and enter the same password in **Master password** and **Confirm password**. By default, the new RDS Custom DB instance uses an automatically generated password for the master user.

When you connect to a non-CDB, the master user is the user for the non-CDB. When you connect to a CDB, the master user is the user for the PDB. To connect to the CDB root, log in to the host, start a SQL client, and create an administrative user with SQL commands.

13. In **DB instance size**, choose a **DB instance class**.

For supported classes, see [DB instance class support for RDS Custom for Oracle \(p. 766\)](#).

14. Choose **Storage** settings.
15. For **RDS Custom security**, do the following:
 - a. For **IAM instance profile**, choose the instance profile for your RDS Custom for Oracle DB instance.

The IAM instance profile must begin with AWSRDSCustom, for example *AWSRDSCustomInstanceProfileForRdsCustomInstance*.
 - b. For **Encryption**, choose **Enter a key ARN** to list the available AWS KMS keys. Then choose your key from the list.

An AWS KMS key is required for RDS Custom. For more information, see [Make sure that you have a symmetric encryption AWS KMS key \(p. 768\)](#).
16. (Optional) Choose **Add new tag** to apply an identifier to this DB instance.

Important

You can tag RDS Custom DB instances when you create them, but don't create or modify the AWSRDSCustom tag that's required for RDS Custom automation. For more information, see [Tagging RDS Custom for Oracle resources \(p. 824\)](#).

17. For **Initial database name**, enter a name or leave the default value ORCL. In Oracle Multitenant, the initial database name is the PDB name.
18. For the remaining sections, specify your preferred RDS Custom DB instance settings. For information about each setting, see [Settings for DB instances \(p. 237\)](#). The following settings don't appear in the console and aren't supported:

- **Processor features**
- **Storage autoscaling**
- **Availability & durability**
- **Password and Kerberos authentication** option in **Database authentication** (only **Password authentication** is supported)
- **Database options** group in **Additional configuration**
- **Performance Insights**
- **Log exports**
- **Enable auto minor version upgrade**
- **Deletion protection**

Backup retention period is supported, but you can't choose **0 days**.

19. Choose **Create database**.

Important

When you create an RDS Custom for Oracle DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

The **View credential details** button appears on the **Databases** page.

To view the master user name and password for the RDS Custom DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the RDS Custom DB instance is available, modify the DB instance to do so. For more information about modifying a DB instance, see [Managing an Amazon RDS Custom for Oracle DB instance \(p. 816\)](#).

20. Choose **Databases** to view the list of RDS Custom DB instances.
21. Choose the RDS Custom DB instance that you just created.

On the RDS console, the details for the new RDS Custom DB instance appear:

- The DB instance has a status of **creating** until the RDS Custom DB instance is created and ready for use. When the state changes to **available**, you can connect to the DB instance. Depending on the instance class and storage allocated, it can take several minutes for the new DB instance to be available.
- **Role** has the value **Instance (RDS Custom)**.
- **RDS Custom automation mode** has the value **Full automation**. This setting means that the DB instance provides automatic monitoring and instance recovery.

AWS CLI

You create an RDS Custom DB instance by using the `create-db-instance` AWS CLI command.

The following options are required:

- `--db-instance-identifier`
- `--db-instance-class` (for a list of supported instance classes, see [DB instance class support for RDS Custom for Oracle \(p. 766\)](#))
- `--engine engine_type` (where `engine-type` is `custom-oracle-ee-cdb` for a CDB and `custom-oracle-ee` for a non-CDB)
- `--engine-version cev` (where `cev` is the name of the custom engine version that you specified in [Creating a CEV \(p. 798\)](#))
- `--kms-key-id`
- `--no-auto-minor-version-upgrade`
- `--custom-iam-instance-profile`

The following example creates an RDS Custom DB instance named `my-cdb-instance`. The database is a CDB. The PDB name is `my-pdb`. The backup retention period is three days.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --engine custom-oracle-ee-cdb \
  --db-instance-identifier my-cdb-instance \
  --engine-version 19.cdb_cev1 \
  --db-name my-pdb \
  --allocated-storage 250 \
  --db-instance-class db.m5.xlarge \
  --db-subnet-group mydbsubnetgroup \
  --master-username myawsuser \
  --master-user-password mypassword \
```

```
--backup-retention-period 3 \
--no-multi-az \
--port 8200 \
--license-model bring-your-own-license \
--kms-key-id my-kms-key \
--no-auto-minor-version-upgrade \
--custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
```

For Windows:

```
aws rds create-db-instance ^
--engine custom-oracle-ee-cdb ^
--db-instance-identifier my-cdb-instance ^
--engine-version 19.cdb_cev1 ^
--db-name my-pdb ^
--allocated-storage 250 ^
--db-instance-class db.m5.xlarge ^
--db-subnet-group mydbsubnetgroup ^
--master-username myawsuser ^
--master-user-password mypassword ^
--backup-retention-period 3 ^
--no-multi-az ^
--port 8200 ^
--license-model bring-your-own-license ^
--kms-key-id my-kms-key ^
--no-auto-minor-version-upgrade ^
--custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
```

Get details about your instance by using the describe-db-instances command.

Example

```
aws rds describe-db-instances --db-instance-identifier my-cdb-instance
```

The following partial output shows the engine, parameter groups, and other information.

```
{
    "DBInstances": [
        {
            "PendingModifiedValues": {},
            "Engine": "custom-oracle-ee-cdb",
            "MultiAZ": false,
            "DBSecurityGroups": [],
            "DBParameterGroups": [
                {
                    "DBParameterGroupName": "default.custom-oracle-ee-cdb-19",
                    "ParameterApplyStatus": "in-sync"
                }
            ],
            "AutomationMode": "full",
            "DBInstanceIdentifier": "my-cdb-instance",
            ...
            "TagList": [
                {
                    "Key": "AWSRDSCustom",
                    "Value": "custom-oracle"
                }
            ]
        }
    ]
}
```

RDS Custom service-linked role

A *service-linked role* gives Amazon RDS Custom access to resources in your AWS account. It makes using RDS Custom easier because you don't have to manually add the necessary permissions. RDS Custom defines the permissions of its service-linked roles, and unless defined otherwise, only RDS Custom can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

When you create an RDS Custom DB instance, both the Amazon RDS and RDS Custom service-linked roles are created (if they don't already exist) and used. For more information, see [Using service-linked roles for Amazon RDS \(p. 2089\)](#).

The first time that you create an RDS Custom for Oracle DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

Connecting to your RDS Custom DB instance using SSH

After you create your RDS Custom DB instance, you can connect to this instance using an SSH client. The procedure is the same as for connecting to an Amazon EC2 instance. For more information, see [Connecting to your Linux instance using SSH](#).

To connect to the DB instance, you need the key pair associated with the instance. RDS Custom creates the key pair on your behalf. The pair name uses the prefix `do-not-delete-rds-custom-ssh-privatekey-db-`. AWS Secrets Manager stores your private key as a secret.

Complete the task in the following steps:

1. [Configure your DB instance to allow SSH connections \(p. 812\)](#)
2. [Retrieve your secret key \(p. 812\)](#)
3. [Connect to your EC2 instance using the ssh utility \(p. 814\)](#)

Configure your DB instance to allow SSH connections

Make sure that your DB instance security group permits inbound connections on port 22 for TCP. To learn how to configure your instance security group, see [Configure your instance security group \(p. 775\)](#).

Retrieve your secret key

Retrieve the secret key using either AWS Management Console or the AWS CLI.

Console

To retrieve the secret key

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose **Configuration**.
4. Note the **Resource ID** value. For example, the resource ID might be `db-ABCDEFGHijklmn0PQRS0123456`.
5. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
6. In the navigation pane, choose **Instances**.

7. Find the name of your EC2 instance, and choose the instance ID associated with it. For example, the EC2 instance ID might be i-abcdefgijklm01234.
8. In **Details**, find **Key pair name**. The pair name includes the resource ID. For example, the pair name might be do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c.
9. In the instance summary, find **Public IPv4 DNS**. For the example, the public Domain Name System (DNS) address might be ec2-12-345-678-901.us-east-2.compute.amazonaws.com.
10. Open the AWS Secrets Manager console at <https://console.aws.amazon.com/secretsmanager/>.
11. Choose the secret that has the same name as your key pair.
12. Choose **Retrieve secret value**.
13. Copy the private key into a text file, and then save the file with the .pem extension. For example, save the file as /tmp/do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem.

AWS CLI

To retrieve the private key, use the AWS CLI.

Example

To find the DB resource ID of your RDS Custom DB instance, use aws rds describe-db-instances.

```
aws rds describe-db-instances \
    --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
    --output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is db-.

```
db-ABCDEFGHIJKLMNOPQRS0123456
```

To find the EC2 instance ID of your DB instance, use aws ec2 describe-instances. The following example uses db-ABCDEFGHIJKLMNOPQRS0123456 for the resource ID.

```
aws ec2 describe-instances \
    --filters "Name>tag:Name,Values=db-ABCDEFGHIJKLMNOPQRS0123456" \
    --output text \
    --query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefgijklm01234
```

To find the key name, specify the EC2 instance ID.

```
aws ec2 describe-instances \
    --instance-ids i-0bdc4219e66944afa \
    --output text \
    --query 'Reservations[*].Instances[*].KeyName'
```

The following sample output shows the key name, which uses the prefix do-not-delete-rds-custom-ssh-privatekey-.

```
do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c
```

To save the private key in a .pem file named after the key, use aws secretsmanager. The following example saves the file in your /tmp directory.

```
aws secretsmanager get-secret-value \
--secret-id do-not-delete-rds-custom-ssh-privatekey-db-
ABCDEFGHIJKLMNOPQRS0123456-0d726c \
--query SecretString \
--output text >/tmp/do-not-delete-rds-custom-ssh-privatekey-db-
ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem
```

Connect to your EC2 instance using the ssh utility

The following example assumes that you created a .pem file that contains your private key.

Change to the directory that contains your .pem file. Using chmod, set the permissions to 400.

```
cd /tmp
chmod 400 do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem
```

To obtain your public DNS name, use the command ec2 describe-instances.

```
aws ec2 describe-instances \
--instance-ids i-abcdefhijklm01234 \
--output text \
--query 'Reservations[*].Instances[*].PublicDnsName'
```

The following sample output shows the public DNS name.

```
ec2-12-345-678-901.us-east-2.compute.amazonaws.com
```

In the ssh utility, specify the .pem file and the public DNS name of the instance.

```
ssh -i \
"do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem" \
ec2-user@ec2-12-345-678-901.us-east-2.compute.amazonaws.com
```

Connecting to your RDS Custom DB instance using AWS Systems Manager

After you create your RDS Custom DB instance, you can connect to it using AWS Systems Manager Session Manager. Session Manager is an Systems Manager capability that you can use to manage Amazon EC2 instances through a browser-based shell or through the AWS CLI. For more information, see [AWS Systems Manager Session Manager](#).

Console

To connect to your DB instance using Session Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose **Configuration**.
4. Note the **Resource ID** for your DB instance. For example, the resource ID might be db-ABCDEFGHIJKLMNOPQRS0123456.

5. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
6. In the navigation pane, choose **Instances**.
7. Look for the name of your EC2 instance, and then click the instance ID associated with it. For example, the instance ID might be i-abcdefgijklm01234.
8. Choose **Connect**.
9. Choose **Session Manager**.
10. Choose **Connect**.

A window opens for your session.

AWS CLI

You can connect to your RDS Custom DB instance using the AWS CLI. This technique requires the Session Manager plugin for the AWS CLI. To learn how to install the plugin, see [Install the Session Manager plugin for the AWS CLI](#).

To find the DB resource ID of your RDS Custom DB instance, use `aws rds describe-db-instances`.

```
aws rds describe-db-instances \
--query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
--output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is db-.

```
db-ABCDEFGHIJKLMNOPQRS0123456
```

To find the EC2 instance ID of your DB instance, use `aws ec2 describe-instances`. The following example uses db-ABCDEFGHIJKLMNOPQRS0123456 for the resource ID.

```
aws ec2 describe-instances \
--filters "Name>tag:Name,Values=db-ABCDEFGHIJKLMNOPQRS0123456" \
--output text \
--query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefgijklm01234
```

Use the `aws ssm start-session` command, supplying the EC2 instance ID in the `--target` parameter.

```
aws ssm start-session --target "i-abcdefgijklm01234"
```

A successful connection looks like the following.

```
Starting session with SessionId: yourid-abcdefgijklm1234
[ssm-user@ip-123-45-67-89 bin]$
```

Managing an Amazon RDS Custom for Oracle DB instance

Amazon RDS Custom supports a subset of the usual management tasks for Amazon RDS DB instances. Following, you can find instructions for the supported RDS Custom for Oracle management tasks using the AWS Management Console and the AWS CLI.

Topics

- [Working with container databases \(CDBs\) in RDS Custom for Oracle \(p. 816\)](#)
- [Working with high availability features for RDS Custom for Oracle \(p. 817\)](#)

- [Tagging RDS Custom for Oracle resources \(p. 824\)](#)
- [Deleting an RDS Custom for Oracle DB instance \(p. 824\)](#)

Working with container databases (CDBs) in RDS Custom for Oracle

You can either create your RDS Custom for Oracle DB instance with the Oracle Multitenant architecture (custom-oracle-ee-cdb engine type) or with the traditional non-CDB architecture (custom-oracle-ee engine type). When you create a container database (CDB), it contains one pluggable database (PDB) and one PDB seed. You can create additional PDBs manually using Oracle SQL.

In the RDS Custom for Oracle shared responsibility model, you are responsible for managing PDBs and creating any additional PDBs. RDS Custom doesn't restrict the number of PDBs. You can manually create, modify, and delete PDBs by connecting to the CDB root and running a SQL command. Create PDBs on an Amazon EBS data volume to prevent the DB instance from going outside the support perimeter.

You can't rename existing PDBs using Amazon RDS APIs. You also can't rename the CDB using the `modify-db-instance` command.

To modify your CDBs or PDBs, complete the following steps:

1. Pause automation to prevent interference with RDS Custom actions.
2. Modify your CDB or PDBs.
3. Back up any modified PDBs.
4. Resume automation.

RDS Custom keeps the CDB root open in the same way as it keeps a non-CDB open. If the state of the CDB root changes, the monitoring and recovery automation attempts to recover the CDB root to the desired state. You receive RDS event notifications when the root CDB is shut down (RDS-EVENT-0004) or restarted (RDS-EVENT-0006), similar to the non-CDB architecture. RDS Custom attempts to open all PDBs in READ WRITE mode at DB instance startup. If some PDBs can't be opened, RDS Custom publishes the following event: tenant database shutdown.

Working with high availability features for RDS Custom for Oracle

To support replication between RDS Custom for Oracle instances, you can configure high availability (HA) with Oracle Data Guard. The primary DB instance automatically synchronizes data to the standby instances.

You can configure your high availability environment in the following ways:

- Configure standby instances in different Availability Zones (AZs) to be resilient to AZ failures.
- Place your standby databases in mounted or read-only mode.
- Fail over or switch over from the primary database to a standby database with no data loss.
- Migrate data by configuring high availability for your on-premises instance, and then failing over or switching over to the RDS Custom standby database.

To learn how to configure high availability, see the whitepaper [Build high availability for Amazon RDS Custom for Oracle using read replicas](#). You can perform the following tasks:

- Use a virtual private network (VPN) tunnel to encrypt data in transit for your high availability instances. Encryption in transit isn't configured automatically by RDS Custom.
- Configure Oracle Fast-Failover Observer (FSFO) to monitor your high availability instances.
- Allow the observer to perform automatic failover when necessary conditions are met.

Pausing and resuming RDS Custom automation

RDS Custom automatically provides monitoring and instance recovery for an RDS Custom for Oracle DB instance. If you need to customize your DB instance, do the following:

1. Pause RDS Custom automation for a specified period. The pause ensures that your customizations don't interfere with RDS Custom automation.
2. Customize the RDS Custom for Oracle DB instance as needed.
3. Do either of the following:
 - Resume automation manually.

Important

Pausing and resuming automation are the only supported automation tasks when modifying an RDS Custom for Oracle DB instance.

- Wait for the pause period to end. In this case, RDS Custom resumes monitoring and instance recovery automatically.

In an on-premises Oracle CDB, you can preserve a specified open mode for PDBs using a built-in command or after a startup trigger. This mechanism brings PDBs to a specified state when the CDB restarts. When opening your CDB, RDS Custom automation always discards any user-specified preserved states and attempts to open all PDBs. If RDS Custom can't open all PDBs, the following event is issued: The following PDBs failed to open: *list-of-PDBs*.

Console

To pause or resume RDS Custom automation

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **RDS Custom automation mode**, choose one of the following options:
 - **Paused** pauses the monitoring and instance recovery for the RDS Custom DB instance. Enter the pause duration that you want (in minutes) for **Automation mode duration**. The minimum value is 60 minutes (default). The maximum value is 1,440 minutes.
 - **Full automation** resumes automation.
5. Choose **Continue** to check the summary of modifications.

A message indicates that RDS Custom will apply the changes immediately.
6. If your changes are correct, choose **Modify DB instance**. Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

On the RDS console, the details for the modification appear. If you paused automation, the **Status** of your RDS Custom DB instance indicates **Automation paused**.
7. (Optional) In the navigation pane, choose **Databases**, and then your RDS Custom DB instance.

In the **Summary** pane, **RDS Custom automation mode** indicates the automation status. If automation is paused, the value is **Paused**. **Automation resumes in *num* minutes**.

AWS CLI

To pause or resume RDS Custom automation, use the [modify-db-instance](#) AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. Control the automation mode with the following parameters:

- `--automation-mode` specifies the pause state of the DB instance. Valid values are `all-paused`, which pauses automation, and `full`, which resumes it.
- `--resume-full-automation-mode-minutes` specifies the duration of the pause. The default value is 60 minutes.

Note

Regardless of whether you specify `--no-apply-immediately` or `--apply-immediately`, RDS Custom applies modifications asynchronously as soon as possible.

In the command response, `ResumeFullAutomationModeTime` indicates the resume time as a UTC timestamp. When the automation mode is `all-paused`, you can use `modify-db-instance` to resume automation mode or extend the pause period. No other `modify-db-instance` options are supported.

The following example pauses automation for `my-custom-instance` for 90 minutes.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance \
  --automation-mode all-paused \
  --resume-full-automation-mode-minutes 90
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier my-custom-instance ^
```

```
--automation-mode all-paused ^
--resume-full-automation-mode-minutes 90
```

The following example extends the pause duration for an extra 30 minutes. The 30 minutes is added to the original time shown in ResumeFullAutomationModeTime.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier my-custom-instance \
--automation-mode all-paused \
--resume-full-automation-mode-minutes 30
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier my-custom-instance ^
--automation-mode all-paused ^
--resume-full-automation-mode-minutes 30
```

The following example resumes full automation for my-custom-instance.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier my-custom-instance \
--automation-mode full \
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier my-custom-instance ^
--automation-mode full
```

In the following partial sample output, the pending AutomationMode value is full.

```
{
    "DBInstance": {
        "PubliclyAccessible": true,
        "MasterUsername": "admin",

```

Modifying the storage for an RDS Custom for Oracle DB instance

Modifying storage for an RDS Custom for Oracle DB instance is similar to modifying storage for an Amazon RDS DB instance, but you can only do the following:

- Increase the allocated storage.
- Change the storage type from io1 to gp2, or gp2 to io1.
- Change the Provisioned IOPS, if you're using the io1 storage type.

The following limitations apply to modifying the storage for an RDS Custom for Oracle DB instance:

- The minimum allocated storage for RDS Custom for Oracle is 40 GiB, and the maximum is 64 TiB.
- As with Amazon RDS, you can't decrease the allocated storage. This is a limitation of Amazon EBS volumes.
- Storage autoscaling isn't supported for RDS Custom DB instances.

- Any storage volumes that you attach manually to your RDS Custom DB instance are outside the support perimeter.

For more information, see [RDS Custom support perimeter and unsupported configurations \(p. 891\)](#).

- Magnetic (standard) storage isn't supported for RDS Custom.

For more information about storage, see [Amazon RDS DB instance storage \(p. 64\)](#).

For general information about storage modification, see [Working with storage for Amazon RDS DB instances \(p. 410\)](#). The following procedures are specific to RDS Custom.

Console

To modify the storage for an RDS Custom for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Make the following changes as needed:
 - a. Enter a new value for **Allocated storage**. It must be greater than the current value, and from 40 GiB–64 TiB.
 - b. Change the value for **Storage type**. You can use General Purpose (gp2) or Provisioned IOPS (io1) storage.
 - c. If using io1 storage, you can change the **Provisioned IOPS** value.
6. Choose **Continue**.
7. Choose **Apply immediately** or **Apply during the next scheduled maintenance window**.
8. Choose **Modify DB instance**.

AWS CLI

To modify the storage for an RDS Custom for Oracle DB instance, use the [modify-db-instance](#) AWS CLI command. Set the following parameters as needed:

- **--allocated-storage** – Amount of storage to be allocated for the DB instance, in gibibytes. It must be greater than the current value, and from 40–65,536 GiB.
- **--storage-type** – The storage type, gp2 or io1.
- **--iops** – Provisioned IOPS for the DB instance, if using the io1 storage type.
- **--apply-immediately** – Use **--apply-immediately** to apply the storage changes immediately.
Or use **--no-apply-immediately** (the default) to apply the changes during the next maintenance window.

The following example changes the storage size of my-custom-instance to 200 GiB, storage type to io1, and Provisioned IOPS to 3000.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
```

```
--db-instance-identifier my-custom-instance \
--storage-type io1 \
--iops 3000 \
--allocated-storage 200 \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier my-custom-instance ^
--storage-type io1 ^
--iops 3000 ^
--allocated-storage 200 ^
--apply-immediately
```

Changing the time zone of an RDS Custom for Oracle DB instance

You change the time zone of an RDS Custom for Oracle DB instance manually. This approach contrasts with RDS for Oracle, where you use the `TIME_ZONE` option in a custom DB option group.

You can change time zones for RDS Custom for Oracle DB instances multiple times. However, we recommend not changing them more than once every 48 hours. We also recommend changing them only when the latest restorable time is within the last 30 minutes.

If you don't follow these recommendations, cleaning up redo logs might remove more logs than intended. Redo log timestamps might also be converted incorrectly to UTC, which can prevent the redo log files from being downloaded and replayed correctly. This in turn can prevent point-in-time recovery (PITR) from performing correctly.

Changing the time zone of an RDS Custom for Oracle DB instance has the following limitations:

- PITR is supported for recovery times before RDS Custom automation is paused, and after automation is resumed.

For more information about PITR, see [Restoring an RDS Custom for Oracle instance to a point in time \(p. 833\)](#).
- Changing the time zone of an existing read replica causes downtime. We recommend changing the time zone of the DB instance before creating read replicas.

You can create a read replica from a DB instance with a modified time zone. For more information about read replicas, see [Working with Oracle replicas for RDS Custom for Oracle \(p. 826\)](#).

Use the following procedures to change the time zone of an RDS Custom for Oracle DB instance.

Make sure to follow these procedures. If they aren't followed, it can result in these issues:

- Disruption of redo log download and replay
- Incorrect redo log timestamps
- Cleanup of redo logs on the host that doesn't use the redo log retention period

To change the time zone for a primary DB instance

1. Pause RDS Custom automation. For more information, see [Pausing and resuming RDS Custom automation \(p. 817\)](#).
2. (Optional) Change the time zone of the DB instance, for example by using the following command.

```
ALTER DATABASE SET TIME_ZONE = 'US/Pacific';
```

3. Shut down the DB instance.
4. Log in to the host and change the system time zone.
5. Start the DB instance.
6. Resume RDS Custom automation.

To change the time zone for a primary DB instance and its read replicas

1. Pause RDS Custom automation on the primary DB instance.
2. Pause RDS Custom automation on the read replicas.
3. (Optional) Change the time zone of the primary and read replicas, for example by using the following command.

```
ALTER DATABASE SET TIME_ZONE = 'US/Pacific';
```

4. Shut down the primary DB instance.
5. Shut down the read replicas.
6. Log in to the host and change the system time zone for the read replicas.
7. Change the system time zone for the primary DB instance.
8. Mount the read replicas.
9. Start the primary DB instance.
10. Resume RDS Custom automation on the primary DB instance and then on the read replicas.

Changing the character set of an RDS Custom for Oracle DB instance

RDS Custom for Oracle defaults to the character set US7ASCII. You might want to specify different character sets to meet language or multibyte character requirements. When you use RDS Custom for Oracle, you can pause automation and then change the character set of your database manually.

Changing the character set of an RDS Custom for Oracle DB instance has the following requirements:

- You can only change the character set on a newly provisioned RDS Custom instance that has an empty or starter database with no application data. For all other scenarios, change the character set using DMU (Database Migration Assistant for Unicode).
- You can only change to a character set supported by RDS for Oracle. For more information, see [Supported DB character sets \(p. 1483\)](#).

To change the character set of an RDS Custom for Oracle DB instance

1. Pause RDS Custom automation. For more information, see [Pausing and resuming RDS Custom automation \(p. 817\)](#).
2. Log in to your database as a user with SYSDBA privileges.
3. Restart the database in restricted mode, change the character set, and then restart the database in normal mode.

Run the following script in your SQL client:

```
SHUTDOWN IMMEDIATE;
```

```
STARTUP RESTRICT;
ALTER DATABASE CHARACTER SET INTERNAL_CONVERT AL32UTF8;
SHUTDOWN IMMEDIATE;
STARTUP;
SELECT VALUE FROM NLS_DATABASE_PARAMETERS WHERE PARAMETER = 'NLS_CHARACTERSET';
```

Verify that the output shows the correct character set:

```
VALUE
-----
AL32UTF8
```

4. Resume RDS Custom automation. For more information, see [Pausing and resuming RDS Custom automation \(p. 817\)](#).

Support for Transparent Data Encryption

RDS Custom supports Transparent Data Encryption (TDE) for RDS Custom for Oracle DB instances.

However, you can't enable TDE using an option in a custom option group as you can in RDS for Oracle. You turn on TDE manually. For information about using Oracle Transparent Data Encryption, see [Securing stored data using Transparent Data Encryption](#) in the Oracle documentation.

Tagging RDS Custom for Oracle resources

You can tag RDS Custom resources as with Amazon RDS resources, but with some important differences:

- Don't create or modify the AWSRDSCustom tag that's required for RDS Custom automation. If you do, you might break the automation.
- Tags added to RDS Custom DB instances during creation are propagated to all other related RDS Custom resources.
- Tags aren't propagated when you add them to RDS Custom resources after DB instance creation.

For general information about resource tagging, see [Tagging Amazon RDS resources \(p. 392\)](#).

Deleting an RDS Custom for Oracle DB instance

To delete an RDS Custom DB instance, do the following:

- Provide the name of the DB instance.
- Clear the option to take a final DB snapshot of the DB instance.
- Choose or clear the option to retain automated backups.

You can delete an RDS Custom DB instance using the console or the CLI. The time required to delete the DB instance can vary depending on the backup retention period (that is, how many backups to delete) and how much data is deleted.

Console

To delete an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance that you want to delete. RDS Custom DB instances show the role **Instance (RDS Custom)**.

3. For **Actions**, choose **Delete**.
4. To retain automated backups, choose **Retain automated backups**.
5. Enter **delete me** in the box.
6. Choose **Delete**.

AWS CLI

You delete an RDS Custom DB instance by using the `delete-db-instance` AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. The remaining parameters are the same as for an Amazon RDS DB instance, with the following exceptions:

- `--skip-final-snapshot` is required.
- `--no-skip-final-snapshot` isn't supported.
- `--final-db-snapshot-identifier` isn't supported.

The following example deletes the RDS Custom DB instance named `my-custom-instance`, and retains automated backups.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
  --db-instance-identifier my-custom-instance \
  --skip-final-snapshot \
  --no-delete-automated-backups
```

For Windows:

```
aws rds delete-db-instance ^
  --db-instance-identifier my-custom-instance ^
  --skip-final-snapshot ^
  --no-delete-automated-backups
```

Working with Oracle replicas for RDS Custom for Oracle

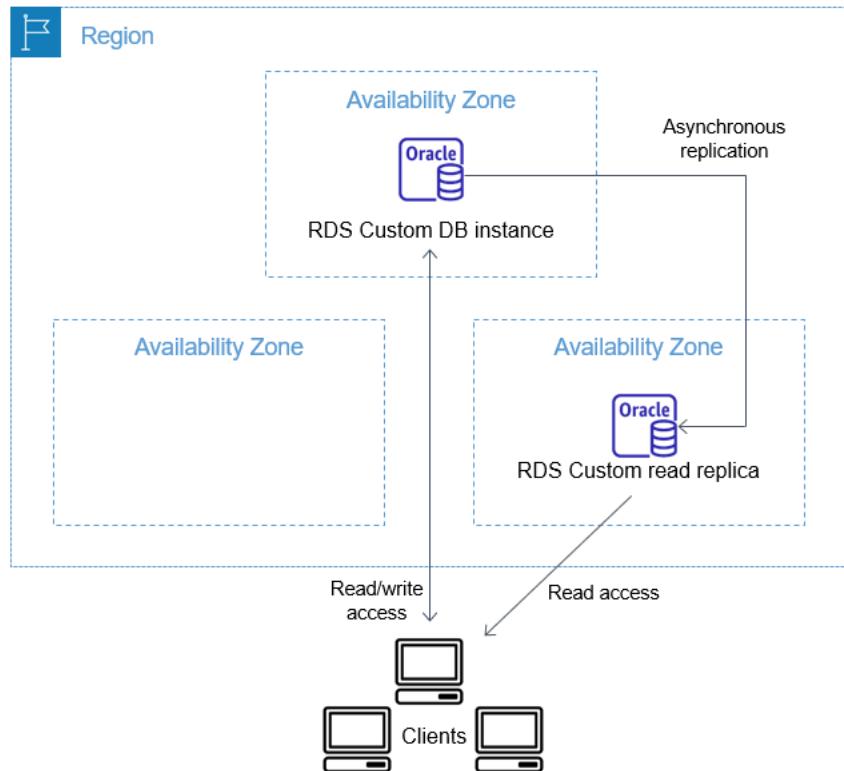

You can create Oracle replicas for RDS Custom for Oracle DB instances. Both container databases (CDBs) and non-CDBs are supported. Creating an Oracle replica is similar to the process in Amazon RDS, but with important differences. For general information about creating and managing Oracle replicas, see [Working with read replicas \(p. 370\)](#) and [Working with read replicas for Amazon RDS for Oracle \(p. 1630\)](#).

Topics

- [Overview of RDS Custom for Oracle replication \(p. 826\)](#)
- [Requirements and limitations for RDS Custom for Oracle replication \(p. 827\)](#)
- [Promoting an RDS Custom for Oracle replica to a standalone DB instance \(p. 829\)](#)

Overview of RDS Custom for Oracle replication

The architecture of RDS Custom for Oracle replication is analogous to RDS for Oracle replication. A primary DB instance replicates asynchronously to one or more Oracle replicas.

As with RDS for Oracle, you can create up to five managed Oracle replicas of your RDS Custom for Oracle primary DB instance. You can also create your own manually configured (external) Oracle replicas. External replicas don't count toward your instance limit. They also lie outside the RDS Custom support perimeter. For more information about the support perimeter, see [RDS Custom support perimeter and unsupported configurations \(p. 891\)](#).

Oracle replica names are based on the database unique name. The format is `DB_UNIQUE_NAME_X`, with letters appended sequentially. For example, if your database unique name is ORCL, the first two replicas are named ORCL_A and ORCL_B. The first six letters, A–F, are reserved for RDS Custom. RDS Custom

copies database parameters from your primary DB instance to the replicas. For more information, see [DB_UNIQUE_NAME](#) in the Oracle documentation.

By default, RDS Custom Oracle replicas use the same backup retention period as your primary DB instance. You can modify the backup retention period to 1–35 days. RDS Custom supports backing up, restoring, and point-in-time recovery (PITR). For more information about backing up and restoring RDS Custom DB instances, see [Backing up and restoring an Amazon RDS Custom for Oracle DB instance \(p. 831\)](#).

You can promote managed Oracle replicas in RDS Custom for Oracle using the console, `promote-read-replica` AWS CLI command, or `PromoteReadReplica` API. If you delete your primary DB instance, and all replicas are healthy, RDS Custom for Oracle promotes your managed replicas to standalone instances automatically. If a replica has paused automation or is outside the support perimeter, you must fix the replica before RDS Custom can promote it automatically. You can only promote external Oracle replicas manually.

Requirements and limitations for RDS Custom for Oracle replication

When you create RDS Custom for Oracle replicas, not all RDS Oracle replica options are supported.

Topics

- [General requirements and limitations \(p. 827\)](#)
- [Networking requirements and limitations \(p. 828\)](#)
- [External replica requirements and limitations \(p. 828\)](#)
- [Replica promotion requirements and limitations \(p. 829\)](#)

General requirements and limitations

RDS Custom for Oracle replicas have the following limitations:

- We recommend that you create Oracle replicas only for RDS Custom for Oracle DB instances created after November 18, 2022. If you need to create Oracle replicas for pre-existing RDS Custom for Oracle DB instances, see [Troubleshooting replica creation for RDS Custom for Oracle \(p. 900\)](#).
- You can create RDS Custom for Oracle replicas in mounted mode only. However, you can manually change the mode of mounted replicas to read-only, and from read-only to mounted. For more information, see the documentation for the `create-db-instance-read-replica` AWS CLI command.
- Cross-Region Oracle replicas aren't supported.
- Make sure not to modify the RDS_DATAGUARD user. This user is reserved for RDS Custom for Oracle automation. Modifying this user can result in undesired outcomes, such as an inability to create Oracle replicas for your RDS Custom for Oracle DB instance.
- You can't change the value of the Oracle Data Guard `CommunicationTimeout` parameter. This parameter is set to 15 seconds for RDS Custom for Oracle DB instances.
- Make sure not to change the replication user password. It is required to administer the Oracle Data Guard configuration on the host. If you change the password, RDS Custom for Oracle might put your Oracle replica outside the support perimeter. For more information, see [RDS Custom support perimeter and unsupported configurations \(p. 891\)](#).

The password is stored in AWS Secrets Manager, tagged with the DB resource ID. Each Oracle replica has its own secret in Secrets Manager. The format for the secret is the following.

```
do-not-delete-rds-custom-db-DB_resource_id-6-digit_UUID-dg
```

- While creating a Oracle replica, RDS Custom temporarily pauses the cleanup of redo log files. In this way, RDS Custom ensures that it can apply these logs to the new Oracle replica after it becomes available.
- If your RDS Custom DB instance is a CDB, we recommend that you don't specify the clause STANDBYS=NONE in a CREATE PLUGGABLE DATABASE command. The goal is to ensure that your standby CDB contains all PDBs if a failover occurs.

Networking requirements and limitations

Make sure that your network configuration supports RDS Custom for Oracle replicas. Consider the following requirements and limitations:

- Make sure to enable port 1140 for both inbound and outbound communication within your virtual private cloud (VPC) for the primary DB instance and all of the replicas. This is required for Oracle Data Guard communication between the read replicas.
- RDS Custom for Oracle validates the network while creating a Oracle replica. If the primary DB instance and the new replica can't connect over the network, RDS Custom for Oracle doesn't create the replica and places it in the INCOMPATIBLE_NETWORK state.
- For external Oracle replicas, such as those you create on Amazon EC2 or on-premises, use another port and listener for Oracle Data Guard replication. Trying to use port 1140 could cause conflicts with RDS Custom automation.
- The /rdsdbdata/config/tnsnames.ora file contains network service names mapped to listener protocol addresses. Note the following requirements and recommendations:
 - Entries in tnsnames.ora prefixed with rds_custom_ are reserved for RDS Custom when handling Oracle replica operations.

When creating manual entries in tnsnames.ora, don't use this prefix.

- In some cases, you might want to switch over or fail over manually, or use failover technologies such as Fast-Start Failover (FSFO). If so, make sure to manually synchronize tnsnames.ora entries from the primary DB instance to all of the standby instances. This recommendation applies to both Oracle replicas managed by RDS Custom and to external Oracle replicas.

RDS Custom automation updates tnsnames.ora entries on only the primary DB instance. Make sure also to synchronize when you add or remove a Oracle replica.

If you don't synchronize the tnsnames.ora files and switch over or fail over manually, Oracle Data Guard on the primary DB instance might not be able to communicate with the Oracle replicas.

External replica requirements and limitations

RDS Custom for Oracle external replicas, which include on-premises replicas, have the following limitations:

- RDS Custom for Oracle detects instance role changes upon manual failover, such as FSFO, for managed Oracle replicas but not for external Oracle replicas.

The role change is noted in the event log. You can also see the new state by using the [describe-db-instances](#) AWS CLI command.

- RDS Custom for Oracle detects high replication lag for managed Oracle replicas but not for external Oracle replicas.

High replication lag produces the Replication has stopped event. You can also see the replication status by using the [describe-db-instances](#) AWS CLI command, but there might be a delay for it to be updated.

- RDS Custom for Oracle doesn't promote external Oracle replicas automatically after you delete your primary DB instance. The automatic promotion feature is available only for managed Oracle replicas. For information about promoting Oracle replicas manually, see the white paper [Enabling high availability with Data Guard on Amazon RDS Custom for Oracle](#).

Replica promotion requirements and limitations

Promoting RDS Custom for Oracle managed Oracle replicas is the same as promoting RDS managed replicas, with some differences. Note the following requirements and limitations for RDS Custom for Oracle:

- You can't promote a replica while RDS Custom for Oracle is backing it up.
- When you promote your Oracle replica, you can't change the backup retention period to 0.
- Make sure not to initiate a failover while RDS Custom for Oracle is promoting your replica. Otherwise, the promotion workflow could become stuck.
- Make sure not to switch over your primary DB instance while RDS Custom for Oracle is promoting your Oracle replica. Otherwise, the promotion workflow could become stuck.
- Make sure not to shut down your primary DB instance while RDS Custom for Oracle is promoting your Oracle replica. Otherwise, the promotion workflow could become stuck.
- Make sure not to attempt to restart replication with your newly promoted DB instance as a target. After RDS Custom for Oracle promotes your Oracle replica, it becomes a standalone DB instance and no longer has the replica role.
- If you issue `delete-db-instance` on the primary DB instance, RDS Custom for Oracle validates that each managed Oracle replica is healthy and available for promotion. A replica might be ineligible for promotion because automation is paused or it is outside the support perimeter. In such cases, RDS Custom for Oracle publishes an event explaining the issue so that you can repair your Oracle replica manually.
- If you maintain external Oracle replicas and delete your primary DB instance, you must promote your external Oracle replicas manually.

For more information, see [Troubleshooting replica promotion for RDS Custom for Oracle \(p. 900\)](#).

Promoting an RDS Custom for Oracle replica to a standalone DB instance

Just as with RDS for Oracle, you can promote an RDS Custom for Oracle replica to a standalone DB instance. When you promote a Oracle replica, RDS Custom for Oracle reboots the DB instance before it becomes available. For more information about promoting Oracle replicas, see [Promoting a read replica to be a standalone DB instance \(p. 377\)](#).

The following steps show the general process for promoting a Oracle replica to a DB instance:

1. Stop any transactions from being written to the primary DB instance.
2. Wait for RDS Custom for Oracle to apply all updates to your Oracle replica.
3. Promote your Oracle replica by choosing the **Promote** option on the Amazon RDS console, the AWS CLI command `promote-read-replica`, or the `PromoteReadReplica` Amazon RDS API operation.

Promoting a Oracle replica takes a few minutes to complete. During the process, RDS Custom for Oracle stops replication and reboots your replica. When the reboot completes, the Oracle replica is available as a standalone DB instance.

Console

To promote an RDS Custom for Oracle replica to a standalone DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the Amazon RDS console, choose **Databases**.
The **Databases** pane appears. Each Oracle replica shows **Replica** in the **Role** column.
3. Choose the RDS Custom for Oracle replica that you want to promote.
4. For **Actions**, choose **Promote**.
5. On the **Promote Oracle replica** page, enter the backup retention period and the backup window for the newly promoted DB instance. You can't set this value to **0**.
6. When the settings are as you want them, choose **Promote Oracle replica**.

AWS CLI

To promote your RDS Custom for Oracle replica to a standalone DB instance, use the AWS CLI [promote-read-replica](#) command.

Example

For Linux, macOS, or Unix:

```
aws rds promote-read-replica \
--db-instance-identifier my-custom-read-replica \
--backup-retention-period 2 \
--preferred-backup-window 23:00-24:00
```

For Windows:

```
aws rds promote-read-replica ^
--db-instance-identifier my-custom-read-replica ^
--backup-retention-period 2 ^
--preferred-backup-window 23:00-24:00
```

RDS API

To promote your RDS Custom for Oracle replica to be a standalone DB instance, call the Amazon RDS API [PromoteReadReplica](#) operation with the required parameter **DBInstanceIdentifier**.

Backing up and restoring an Amazon RDS Custom for Oracle DB instance

Like Amazon RDS, RDS Custom creates and saves automated backups of your RDS Custom for Oracle DB instance during the backup window of your DB instance. You can also back up your DB instance manually.

The procedure is identical to taking a snapshot of an Amazon RDS DB instance. The first snapshot of an RDS Custom DB instance contains the data for the full DB instance. Subsequent snapshots are incremental.

Restore DB snapshots using either the AWS Management Console or the AWS CLI.

Topics

- [Creating an RDS Custom for Oracle snapshot \(p. 831\)](#)
- [Restoring from an RDS Custom for Oracle DB snapshot \(p. 832\)](#)
- [Restoring an RDS Custom for Oracle instance to a point in time \(p. 833\)](#)
- [Deleting an RDS Custom for Oracle snapshot \(p. 836\)](#)
- [Deleting RDS Custom for Oracle automated backups \(p. 836\)](#)

Creating an RDS Custom for Oracle snapshot

RDS Custom for Oracle creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. When your DB instance contains a container database (CDB), the snapshot of the instance includes the root CDB and all PDBs.

When you create an RDS Custom for Oracle snapshot, specify which RDS Custom DB instance to back up. Give your snapshot a name so you can restore from it later.

When you create a snapshot, RDS Custom for Oracle creates an Amazon EBS snapshot for every volume attached to the DB instance. RDS Custom for Oracle uses the EBS snapshot of the root volume to register a new Amazon Machine Image (AMI). To make snapshots easy to associate with a specific DB instance, they're tagged with `DBSnapshotIdentifier`, `DbiResourceId`, and `VolumeType`.

Creating a DB snapshot results in a brief I/O suspension. This suspension can last from a few seconds to a few minutes, depending on the size and class of your DB instance. The snapshot creation time varies with the size of your database. Because the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects snapshot creation time. To learn more about creating snapshots, see [Creating a DB snapshot \(p. 448\)](#).

Create an RDS Custom for Oracle snapshot using the console or the AWS CLI.

Console

To create an RDS Custom snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. In the list of RDS Custom DB instances, choose the instance for which you want to take a snapshot.
4. For **Actions**, choose **Take snapshot**.

The **Take DB snapshot** window appears.

5. For **Snapshot name**, enter the name of the snapshot.

6. Choose **Take snapshot**.

AWS CLI

You create a snapshot of an RDS Custom DB instance by using the [create-db-snapshot](#) AWS CLI command.

Specify the following options:

- `--db-instance-identifier` – Identifies which RDS Custom DB instance you are going to back up
- `--db-snapshot-identifier` – Names your RDS Custom snapshot so you can restore from it later

In this example, you create a DB snapshot called *my-custom-snapshot* for an RDS Custom DB instance called *my-custom-instance*.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
  --db-instance-identifier my-custom-instance \
  --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds create-db-snapshot ^
  --db-instance-identifier my-custom-instance ^
  --db-snapshot-identifier my-custom-snapshot
```

Restoring from an RDS Custom for Oracle DB snapshot

When you restore an RDS Custom for Oracle DB instance, you provide the name of the DB snapshot and a name for the new instance. You can't restore from a snapshot to an existing RDS Custom DB instance. A new RDS Custom for Oracle DB instance is created when you restore.

The restore process differs in the following ways from restore in Amazon RDS:

- Before restoring a snapshot, RDS Custom for Oracle backs up existing configuration files. These files are available on the restored instance in the directory `/rdsbdbdata/config/backup`. RDS Custom for Oracle restores the DB snapshot with default parameters and overwrites the previous database configuration files with existing ones. Thus, the restored instance doesn't preserve custom parameters and changes to database configuration files.
- The restored database has the same name as in the snapshot. You can't specify a different name. (For RDS Custom for Oracle, the default is ORCL.)

Console

To restore an RDS Custom DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.

4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore DB instance** page, for **DB instance identifier**, enter the name for your restored RDS Custom DB instance.
6. Choose **Restore DB instance**.

AWS CLI

You restore an RDS Custom DB snapshot by using the [restore-db-instance-from-db-snapshot](#) AWS CLI command.

If the snapshot you are restoring from is for a private DB instance, make sure to specify both the correct db-subnet-group-name and no-publicly-accessible. Otherwise, the DB instance defaults to publicly accessible. The following options are required:

- **db-snapshot-identifier** – Identifies the snapshot from which to restore
- **db-instance-identifier** – Specifies the name of the RDS Custom DB instance to create from the DB snapshot
- **custom-iam-instance-profile** – Specifies the instance profile associated with the underlying Amazon EC2 instance of an RDS Custom DB instance.

The following code restores the snapshot named `my-custom-snapshot` for `my-custom-instance`.

Example

For Linux, macOS, or Unix:

```
aws restore-db-instance-from-db-snapshot \
--db-snapshot-identifier my-custom-snapshot \
--db-instance-identifier my-custom-instance \
--custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
--no-publicly-accessible
```

For Windows:

```
aws restore-db-instance-from-db-snapshot ^
--db-snapshot-identifier my-custom-snapshot ^
--db-instance-identifier my-custom-instance ^
--custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
--no-publicly-accessible
```

Restoring an RDS Custom for Oracle instance to a point in time

You can restore a DB instance to a specific point in time (PITR), creating a new DB instance. To support PITR, your DB instances must have backup retention set to a nonzero value.

The latest restorable time for an RDS Custom for Oracle DB instance depends on several factors, but is typically within 5 minutes of the current time. To see the latest restorable time for a DB instance, use the AWS CLI [describe-db-instances](#) command and look at the value returned in the LatestRestorableTime field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose **Automated backups**.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose **Automated backups** in the Amazon RDS console.

For general information about PITR, see [Restoring a DB instance to a specified time \(p. 499\)](#).

Topics

- [PITR considerations for RDS Custom for Oracle \(p. 834\)](#)

PITR considerations for RDS Custom for Oracle

In RDS Custom for Oracle, PITR differs in the following important ways from PITR in Amazon RDS:

- The restored database has the same name as in the source DB instance. You can't specify a different name. The default is ORCL.
- AWSRDSCustomIamRolePolicy requires new permissions. For more information, see [Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance \(p. 771\)](#).
- All RDS Custom for Oracle DB instances must have backup retention set to a nonzero value.
- If you change the operating system or DB instance time zone, PITR might not work. For information about changing time zones, see [Changing the time zone of an RDS Custom for Oracle DB instance \(p. 822\)](#).
- If you set automation to ALL_PAUSED, RDS Custom pauses the upload of archived redo logs, including logs created before the latest restorable time (LRT). We recommend that you pause automation for a brief period.

To illustrate, assume that your LRT is 10 minutes ago. You pause automation. During the pause, RDS Custom doesn't upload archived redo logs. If your DB instance crashes, you can only recover to a time before the LRT that existed when you paused. When you resume automation, RDS Custom resumes uploading logs. The LRT advances. Normal PITR rules apply.

- In RDS Custom, you can manually specify an arbitrary number of hours to retain archived redo logs before RDS Custom deletes them after upload. In RDS Custom, specify the number of hours manually in the following file: /opt/aws/rdscustomagent/config/redo_logs_custom_configuration.json. The format is {"archivedLogRetentionHours" : "*num_of_hours*"}. The number must be an integer in the range 1–840.
- Assume that you plug a non-CDB into a container database (CDB) as a PDB and then attempt PITR. The operation succeeds only if you previously backed up the PDB. After you create or modify a PDB, we recommend that you always back it up.
- We recommend that you don't customize database initialization parameters. For example, modifying the following parameters affects PITR:
 - CONTROL_FILE_RECORD_KEEP_TIME affects the rules for uploading and deleting logs.
 - LOG_ARCHIVE_DEST_n doesn't support multiple destinations.
 - ARCHIVE_LAG_TARGET affects the latest restorable time.
- If you customize database initialization parameters, we strongly recommend that you only customize the following:
 - COMPATIBLE
 - MAX_STRING_SIZE
 - DB_FILES
 - UNDO_TABLESPACE
 - ENABLE_PLUGGABLE_DATABASE
 - CONTROL_FILES
 - AUDIT_TRAIL
 - AUDIT_TRAIL_DEST

For all other initialization parameters, RDS Custom restores the default values. If you modify a parameter that isn't in the preceding list, it might have an adverse effect on PITR and lead to unpredictable results. For example, CONTROL_FILE_RECORD_KEEP_TIME affects the rules for uploading and deleting logs.

You can restore an RDS Custom DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore an RDS Custom DB instance to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Automated backups**.
3. Choose the RDS Custom DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.
The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

If you chose **Custom**, enter the date and time to which you want to restore the instance.

Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

6. For **DB instance identifier**, enter the name of the target restored RDS Custom DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class.
8. Choose **Restore to point in time**.

AWS CLI

You restore a DB instance to a specified time by using the [restore-db-instance-to-point-in-time](#) AWS CLI command to create a new RDS Custom DB instance.

Use one of the following options to specify the backup to restore from:

- `--source-db-instance-identifier mysourcedbinstance`
- `--source-dbi-resource-id dbinstanceresourceID`
- `--source-db-instance-automated-backups-arn backupARN`

The `custom-iam-instance-profile` option is required.

The following example restores `my-custom-db-instance` to a new DB instance named `my-restored-custom-db-instance`, as of the specified time.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
    --source-db-instance-identifier my-custom-db-instance \
    --target-db-instance-identifier my-restored-custom-db-instance \
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
    --restore-time 2022-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
--source-db-instance-identifier my-custom-db-instance ^
--target-db-instance-identifier my-restored-custom-db-instance ^
--custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
--restore-time 2022-10-14T23:45:00.000Z
```

Deleting an RDS Custom for Oracle snapshot

You can delete DB snapshots managed by RDS Custom for Oracle when you no longer need them. The deletion procedure is the same for both Amazon RDS and RDS Custom DB instances.

The Amazon EBS snapshots for the binary and root volumes remain in your account for a longer time because they might be linked to some instances running in your account or to other RDS Custom for Oracle snapshots. These EBS snapshots are automatically deleted after they're no longer related to any existing RDS Custom for Oracle resources (DB instances or backups).

Console

To delete a snapshot of an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete snapshot**.
5. Choose **Delete** on the confirmation page.

AWS CLI

To delete an RDS Custom snapshot, use the AWS CLI command `delete-db-snapshot`.

The following option is required:

- `--db-snapshot-identifier` – The snapshot to be deleted

The following example deletes the `my-custom-snapshot` DB snapshot.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-snapshot \
--db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds delete-db-snapshot ^
--db-snapshot-identifier my-custom-snapshot
```

Deleting RDS Custom for Oracle automated backups

You can delete retained automated backups for RDS Custom for Oracle when they are no longer needed. The procedure is the same as the procedure for deleting Amazon RDS backups.

Console

To delete a retained automated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Automated backups**.
3. Choose **Retained**.
4. Choose the retained automated backup that you want to delete.
5. For **Actions**, choose **Delete**.
6. On the confirmation page, enter **delete me** and choose **Delete**.

AWS CLI

You can delete a retained automated backup by using the AWS CLI command [delete-db-instance-automated-backup](#).

The following option is used to delete a retained automated backup:

- **--dbi-resource-id** – The resource identifier for the source RDS Custom DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup by using the AWS CLI command [describe-db-instance-automated-backups](#).

The following example deletes the retained automated backup with source DB instance resource identifier `custom-db-123ABCEXAMPLE`.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
--dbi-resource-id custom-db-123ABCEXAMPLE
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
--dbi-resource-id custom-db-123ABCEXAMPLE
```

Upgrading a DB instance for Amazon RDS Custom for Oracle

You can upgrade an Amazon RDS Custom DB instance by modifying it to use a new custom engine version (CEV). For general information about upgrades, see [Upgrading a DB instance engine version \(p. 360\)](#).

Topics

- [Requirements and considerations for RDS Custom for Oracle upgrades \(p. 838\)](#)
- [Viewing valid upgrade targets for RDS Custom for Oracle DB instances \(p. 839\)](#)
- [Upgrading an RDS Custom DB instance \(p. 839\)](#)
- [Viewing pending upgrades for RDS Custom DB instances \(p. 840\)](#)
- [Troubleshooting an upgrade failure for an RDS Custom for Oracle DB instance \(p. 841\)](#)

Requirements and considerations for RDS Custom for Oracle upgrades

Before upgrading your DB instance, note the following requirements:

- You can upgrade your DB instance to a new CEV only if it already exists.
- You can upgrade your DB instance to a new CEV only if it uses the same installation parameter settings in the manifest. For example, you can't upgrade a database that uses the default Oracle home to a CEV that uses a nondefault Oracle home.
- You can upgrade your DB instance to a new minor version only. For example, you can't upgrade a DB instance using an Oracle Database 12c CEV to an Oracle Database 19c CEV.

Consider the following:

- We strongly recommend that you upgrade your RDS Custom for Oracle DB instance using CEVs. RDS Custom for Oracle automation synchronizes the patch metadata with the database binary on your DB instance.

In special circumstances, RDS Custom supports applying a "one-off" patch directly to the underlying Amazon EC2 instance directly using OPATCH. A valid use case might be a patch that you want to apply immediately, but the RDS Custom team is upgrading the CEV feature, causing a delay. To apply a patch manually, perform the following steps:

1. Pause RDS Custom automation.
2. Apply your patch to the database binaries on the Amazon EC2 instance.
3. Resume RDS Custom automation.

A disadvantage of the preceding technique is that you must apply the patch manually to every instance that you want to upgrade. In contrast, when you create a new CEV, you can create or upgrade multiple DB instances using the same CEV.

- When you upgrade your primary DB instance, RDS Custom for Oracle upgrades your read replicas automatically. You don't have to upgrade read replicas manually.
- When you upgrade a CEV, RDS Custom deletes the data in the bin volume of your DB instance.
- When you upgrade a container database (CDB), RDS Custom checks that all PDBs are open or could be opened. If these conditions aren't met, RDS Custom stops the check and returns the database to its original state without attempting the upgrade. If the conditions are met, RDS Custom patches the CDB root first, and then patches all other PDBs (including PDB\$SEED) in parallel.

After the patching process completes, RDS Custom attempts to open all PDBs. If any PDBs fail to open, you receive the following event: The following PDBs failed to open: *List-of-PDBs*. If RDS Custom fails to patch the CDB root or any PDBs, the instance is put into the PATCH_DB_FAILED state.

- You might want to perform a major version upgrade and a conversion of non-CDB to CDB at the same time. In this case, we recommend that you complete this goal in the following process:
 1. Create a new RDS Custom DB instance that uses the Oracle Multitenant architecture.
 2. Plug in a non-CDB into your CDB root, creating it as a PDB. Make sure that the non-CDB is the same major version as your CDB.
 3. Convert your PDB by running the `noncdb_to_pdb.sql` Oracle script.
 4. Validate your CDB instance.
 5. Upgrade your CDB instance.

Viewing valid upgrade targets for RDS Custom for Oracle DB instances

You can see existing CEVs on the **Custom engine versions** page in the AWS Management Console.

You can also use the `describe-db-engine-versions` AWS CLI command to find valid upgrades for your DB instances, as shown in the following example. This example assumes that a DB instance was created using the version 19.my_cev1, and that the upgrade versions 19.my_cev2 and 19.my_cev exist.

```
aws rds describe-db-engine-versions --engine custom-oracle-ee --engine-version 19.my_cev1
```

The output resembles the following.

```
{  
    "DBEngineVersions": [  
        {  
            "Engine": "custom-oracle-ee",  
            "EngineVersion": "19.my_cev1",  
            ...  
            "ValidUpgradeTarget": [  
                {  
                    "Engine": "custom-oracle-ee",  
                    "EngineVersion": "19.my_cev2",  
                    "Description": "19.my_cev2 description",  
                    "AutoUpgrade": false,  
                    "IsMajorVersionUpgrade": false  
                },  
                {  
                    "Engine": "custom-oracle-ee",  
                    "EngineVersion": "19.my_cev3",  
                    "Description": "19.my_cev3 description",  
                    "AutoUpgrade": false,  
                    "IsMajorVersionUpgrade": false  
                }  
            ]  
            ...  
        }  
    ]  
}
```

Upgrading an RDS Custom DB instance

To upgrade your RDS Custom DB instance, you modify it to use a new CEV.

Read replicas managed by RDS Custom are automatically upgraded after the primary DB instance is upgraded.

Console

To upgrade an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **DB engine version**, choose the CEV to upgrade to, such as `19.my_cev3`.
5. Choose **Continue** to check the summary of modifications.
Choose **Apply immediately** to apply the changes immediately.
6. If your changes are correct, choose **Modify DB instance**. Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To upgrade an RDS Custom DB instance, use the `modify-db-instance` AWS CLI command with the following parameters:

- `--db-instance-identifier` – The DB instance to be upgraded
- `--engine-version` – The new CEV
- `--no-apply-immediately | --apply-immediately` – Whether to perform the upgrade immediately or wait until the scheduled maintenance window

The following example upgrades `my-custom-instance` to version `19.my_cev3`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance \
  --engine-version 19.my_cev3 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier my-custom-instance ^
  --engine-version 19.my_cev3 ^
  --apply-immediately
```

Viewing pending upgrades for RDS Custom DB instances

You can see pending upgrades for your Amazon RDS Custom DB instances by using the `describe-db-instances` or `describe-pending-maintenance-actions` AWS CLI command.

However, this approach doesn't work if you used the `--apply-immediately` option or if the upgrade is in progress.

The following `describe-db-instances` command shows pending upgrades for `my-custom-instance`.

```
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The output resembles the following.

```
{  
    "DBInstances": [  
        {  
            "DBInstanceIdentifier": "my-custom-instance",  
            "EngineVersion": "19.my_cev1",  
            ...  
            "PendingModifiedValues": {  
                "EngineVersion": "19.my_cev3"  
            }  
        }  
    ]  
}
```

The following shows use of the `describe-pending-maintenance-actions` command.

```
aws rds describe-pending-maintenance-actions
```

The output resembles the following.

```
{  
    "PendingMaintenanceActions": [  
        {  
            "ResourceIdentifier": "arn:aws:rds:us-west-2:123456789012:instance:my-custom-instance",  
            "PendingMaintenanceActionDetails": [  
                {  
                    "Action": "db-upgrade",  
                    "Description": "Upgrade to 19.my_cev3"  
                }  
            ]  
        }  
    ]  
}
```

Troubleshooting an upgrade failure for an RDS Custom for Oracle DB instance

If an RDS Custom DB instance upgrade fails, an RDS event is generated and the DB instance status becomes `upgrade-failed`.

You can see this status by using the `describe-db-instances` AWS CLI command, as shown in the following example.

```
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The output resembles the following.

```
{  
    "DBInstances": [  
        {  
            "DBInstanceIdentifier": "my-custom-instance",  
            "EngineVersion": "19.my_cev1",  
            ...  
        }  
    ]  
}
```

```
    ...
    "PendingModifiedValues": {
        "EngineVersion": "19.my_cev3"
    }
}
]
}
```

After an upgrade failure, all database actions are blocked except for modifying the DB instance to perform the following tasks:

- Retrying the same upgrade
- Pausing and resuming RDS Custom automation
- Point-in-time recovery (PITR)
- Deleting the DB instance

Note

If automation has been paused for the RDS Custom DB instance, you can't retry the upgrade until you resume automation.

The same actions apply to an upgrade failure for an RDS-managed read replica as for the primary.

For more information, see [Troubleshooting upgrades for RDS Custom for Oracle \(p. 899\)](#).

Working with RDS Custom for SQL Server

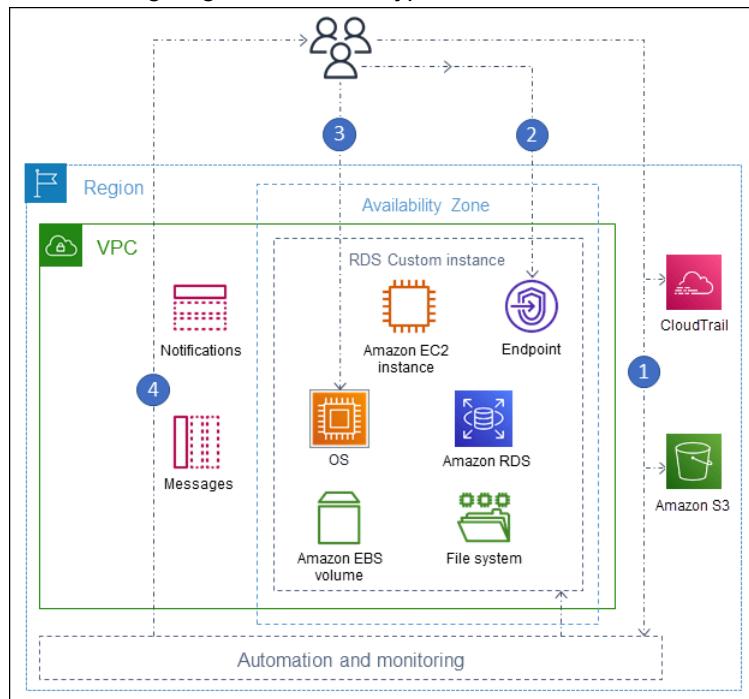

Following, you can find instructions for creating, managing, and maintaining your RDS Custom for SQL Server DB instances.

Topics

- [RDS Custom for SQL Server workflow \(p. 843\)](#)
- [Requirements and limitations for Amazon RDS Custom for SQL Server \(p. 845\)](#)
- [Setting up your environment for Amazon RDS Custom for SQL Server \(p. 847\)](#)
- [Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server \(p. 860\)](#)
- [Managing an Amazon RDS Custom for SQL Server DB instance \(p. 868\)](#)
- [Backing up and restoring an Amazon RDS Custom for SQL Server DB instance \(p. 877\)](#)
- [Migrating an on-premises database to Amazon RDS Custom for SQL Server \(p. 885\)](#)
- [Upgrading a DB instance for Amazon RDS Custom for SQL Server \(p. 888\)](#)

RDS Custom for SQL Server workflow

The following diagram shows the typical workflow for RDS Custom for SQL Server.

The steps are as follows:

1. Create an RDS Custom for SQL Server DB instance from an engine version offered by RDS Custom.

For more information, see [Creating an RDS Custom for SQL Server DB instance \(p. 860\)](#).

2. Connect your application to the RDS Custom DB instance endpoint.

For more information, see [Connecting to your RDS Custom DB instance using AWS Systems Manager \(p. 863\)](#) and [Connecting to your RDS Custom DB instance using RDP \(p. 865\)](#).

3. (Optional) Access the host to customize your software.

4. Monitor notifications and messages generated by RDS Custom automation.

Creating a DB instance for RDS Custom

You create your RDS Custom DB instance using the `create-db-instance` command. The procedure is similar to creating an Amazon RDS instance. However, some of the parameters are different. For more information, see [Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server \(p. 860\)](#).

Database connection

Like an Amazon RDS DB instance, your RDS Custom for SQL Server DB instance resides in a VPC. Your application connects to the RDS Custom instance using a client such as SQL Server Management Suite (SSMS), just as in RDS for SQL Server.

RDS Custom customization

You can access the RDS Custom host to install or customize software. To avoid conflicts between your changes and the RDS Custom automation, you can pause the automation for a specified period. During this period, RDS Custom doesn't perform monitoring or instance recovery. At the end of the period, RDS Custom resumes full automation. For more information, see [Pausing and resuming RDS Custom automation \(p. 868\)](#).

Requirements and limitations for Amazon RDS Custom for SQL Server

Following, you can find a summary of the Amazon RDS Custom for SQL Server requirements and limitations for quick reference. Requirements and limitations also appear in the relevant sections.

Topics

- [Region and version availability \(p. 845\)](#)
- [General requirements for RDS Custom for SQL Server \(p. 845\)](#)
- [DB instance class support for RDS Custom for SQL Server \(p. 845\)](#)
- [Limitations for RDS Custom for SQL Server \(p. 846\)](#)

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Amazon RDS Custom for SQL Server, see [RDS Custom \(p. 110\)](#).

General requirements for RDS Custom for SQL Server

Make sure to follow these requirements for Amazon RDS Custom for SQL Server:

- Use the instance classes shown in [DB instance class support for RDS Custom for SQL Server \(p. 845\)](#). The only storage types supported are solid state drives (SSD) of types gp2 and io1. The maximum storage limit is 16 TiB.
- Make sure that you have a symmetric encryption AWS KMS key to create an RDS Custom DB instance. For more information, see [Make sure that you have a symmetric encryption AWS KMS key \(p. 851\)](#).
- Make sure that you create an AWS Identity and Access Management (IAM) role and instance profile. For more information, see [Creating your IAM role and instance profile manually \(p. 852\)](#).
- Make sure to supply a networking configuration that RDS Custom can use to access other AWS services. For specific requirements, see [Configure networking, instance profile, and encryption \(p. 849\)](#).
- The combined number of RDS Custom and Amazon RDS DB instances can't exceed your quota limit. For example, if your quota is 40 DB instances, you can have 20 RDS Custom for SQL Server DB instances and 20 Amazon RDS DB instances.

DB instance class support for RDS Custom for SQL Server

RDS Custom for SQL Server supports the DB instance classes shown in the following table.

SQL Server edition	RDS Custom support
Enterprise Edition	db.r5.xlarge–db.r5.24xlarge db.m5.xlarge–db.m5.24xlarge
Standard Edition	db.r5.large–db.r5.24xlarge db.m5.large–db.m5.24xlarge

SQL Server edition	RDS Custom support
Web Edition	db.r5.large–db.r5.4xlarge db.m5.large–db.m5.4xlarge

Limitations for RDS Custom for SQL Server

The following limitations apply to RDS Custom for SQL Server:

- You can't provide your own custom DB engine version.
- You can't provide your own AMI.
- You can't create read replicas in Amazon RDS for RDS Custom for SQL Server DB instances. However, you can configure high availability manually using Always On Availability Groups. For more information, see [Working with high availability features for RDS Custom for SQL Server \(p. 868\)](#).
- You can't modify the time zone of an existing RDS Custom for SQL Server DB instance.
- You can't modify the server-level collation of an existing RDS Custom for SQL Server DB instance.
- Changes to the Microsoft Windows operating system or C: drive don't persist when you replace an Amazon EC2 instance. However, you can redo those changes using automation.
- Not all options are supported. For example, when you create an RDS Custom for SQL Server DB instance, you can't do the following:
 - Change the number of CPU cores and threads per core on the DB instance class.
 - Turn on storage autoscaling.
 - Create a Multi-AZ deployment. However, you can configure high availability manually using Always On Availability Groups. For more information, see [Working with high availability features for RDS Custom for SQL Server \(p. 868\)](#).
 - Configure Kerberos authentication using the AWS Management Console. However, you can configure Windows Authentication manually and use Kerberos.
 - Specify your own DB parameter group, option group, or character set.
 - Turn on Performance Insights.
 - Turn on automatic minor version upgrade.
- The maximum DB instance storage is 16 TiB.

Setting up your environment for Amazon RDS Custom for SQL Server

Before you create and manage a DB instance for Amazon RDS Custom for SQL Server DB instance, make sure to perform the following tasks.

Contents

- [Prerequisites for setting up RDS Custom for SQL Server \(p. 847\)](#)
- [Download and install the AWS CLI \(p. 848\)](#)
- [Grant required permissions to your IAM principal \(p. 848\)](#)
- [Configure networking, instance profile, and encryption \(p. 849\)](#)
 - [Configuring with AWS CloudFormation \(p. 849\)](#)
 - [Resources created by CloudFormation \(p. 849\)](#)
 - [Downloading the template file \(p. 850\)](#)
 - [Configuring resources using CloudFormation \(p. 850\)](#)
 - [Configuring manually \(p. 851\)](#)
 - [Make sure that you have a symmetric encryption AWS KMS key \(p. 851\)](#)
 - [Creating your IAM role and instance profile manually \(p. 852\)](#)
 - [Create the AWSRDSCustomSQLServerInstanceRole IAM role \(p. 852\)](#)
 - [Add an access policy to AWSRDSCustomSQLServerInstanceRole \(p. 852\)](#)
 - [Create your RDS Custom for SQL Server instance profile \(p. 856\)](#)
 - [Add AWSRDSCustomSQLServerInstanceRole to your RDS Custom for SQL Server instance profile \(p. 856\)](#)
 - [Configuring your VPC manually \(p. 856\)](#)
 - [Configure your VPC security group \(p. 857\)](#)
 - [Configure endpoints for dependent AWS services \(p. 857\)](#)
 - [Configure the instance metadata service \(p. 859\)](#)

Prerequisites for setting up RDS Custom for SQL Server

Before creating an RDS Custom for SQL Server DB instance, make sure that your environment meets the requirements described in this topic. Not all of them require action from you; if any action is necessary, the corresponding section describes it.

As part of this setup process, make sure to configure the specified AWS Identity and Access Management (IAM) users and roles. These are either used to create an RDS Custom DB instance or passed as a parameter in a creation request. If the account that you're using is part of an AWS organization, it might have service control policies (SCPs) restricting account level permissions. Make sure that the SCPs don't restrict the permissions on IAM users and roles that you create using the following procedures. For more information about SCPs, see [Service control policies \(SCPs\)](#) in the *AWS Organizations User Guide*. Use the [describe-organization](#) AWS CLI command to check whether your account is part of an AWS organization.

For each task, you can find descriptions following for the requirements and limitations specific to that task. For example, when you create your RDS Custom for SQL Server DB instance, use one of the SQL Server instances listed in [DB instance class support for RDS Custom for SQL Server \(p. 845\)](#).

For general requirements that apply to RDS Custom for SQL Server, see [General requirements for RDS Custom for SQL Server \(p. 845\)](#).

Download and install the AWS CLI

You can use the AWS Command Line Interface (AWS CLI) to use RDS Custom features. You can use either version 1 or version 2 of the AWS CLI. For information about downloading and installing the AWS CLI, see [Installing or updating the latest version of the AWS CLI](#).

If you plan to access RDS Custom only from the AWS Management Console, skip this step.

If you have already downloaded the AWS CLI for Amazon RDS or RDS Custom for Oracle, skip this step.

Grant required permissions to your IAM principal

You use an IAM role or IAM user (referred to as the *IAM principal*) for creating an RDS Custom for SQL Server DB instance using the console or CLI. This IAM principal must have either of the following policies for successful DB instance creation:

- The `AdministratorAccess` policy
- The `AmazonRDSFullAccess` policy with the following additional permissions:

```
iam:SimulatePrincipalPolicy
cloudtrail>CreateTrail
cloudtrail:StartLogging
s3>CreateBucket
s3:PutBucketPolicy
s3:PutBucketObjectLockConfiguration
s3:PutBucketVersioning
kms>CreateGrant
kms:DescribeKey
```

For more information about the `kms:CreateGrant` permission, see [AWS KMS key management \(p. 2004\)](#).

The following sample JSON policy grants the required permissions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ValidateIamRole",
            "Effect": "Allow",
            "Action": "iam:SimulatePrincipalPolicy",
            "Resource": "*"
        },
        {
            "Sid": "CreateCloudTrail",
            "Effect": "Allow",
            "Action": [
                "cloudtrail>CreateTrail",
                "cloudtrail:StartLogging"
            ],
            "Resource": "arn:aws:cloudtrail:*::trail/do-not-delete-rds-custom-*"
        },
        {
            "Sid": "CreateS3Bucket",
            "Effect": "Allow",
            "Action": [
                "s3>CreateBucket",
                "s3:PutBucketPolicy",
                "s3:PutBucketObjectLockConfiguration",
                "s3:PutBucketVersioning"
            ]
        }
    ]
}
```

```
        ],
        "Resource": "arn:aws:s3:::do-not-delete-rds-custom-*"
    },
    {
        "Sid": "CreateKmsGrant",
        "Effect": "Allow",
        "Action": [
            "kms:CreateGrant",
            "kms:DescribeKey"
        ],
        "Resource": "*"
    }
]
```

Also, the IAM principal requires the `iam:PassRole` permission on the IAM role. That must be attached to the instance profile passed in the `custom-iam-instance-profile` parameter in the request to create the RDS Custom DB instance. The instance profile and its attached role are created later in [Configure networking, instance profile, and encryption \(p. 849\)](#).

Make sure that the previously listed permissions aren't restricted by service control policies (SCPs), permission boundaries, or session policies associated with the IAM principal.

Configure networking, instance profile, and encryption

You can configure your IAM instance profile role, virtual private cloud (VPC), and AWS KMS symmetric encryption key by using either of the following processes:

- [Configuring with AWS CloudFormation \(p. 849\)](#) (recommended)
- [Configuring manually \(p. 851\)](#)

If your account is part of an AWS organization, make sure that the permissions required by the instance profile role aren't restricted by service control policies (SCPs).

The following networking configurations are designed to work best with DB instances that aren't publicly accessible. That is, you can't connect directly to the DB instance from outside the VPC.

Configuring with AWS CloudFormation

To simplify setup, you can use an AWS CloudFormation template file to create a CloudFormation stack. To learn how to create stacks, see [Creating a stack on the AWS CloudFormation console](#) in the *AWS CloudFormation User Guide*.

For a tutorial on how to launch Amazon RDS Custom for SQL Server using an AWS CloudFormation template, see [Get started with Amazon RDS Custom for SQL Server using an AWS CloudFormation template](#) in the *AWS Database Blog*.

Topics

- [Resources created by CloudFormation \(p. 849\)](#)
- [Downloading the template file \(p. 850\)](#)
- [Configuring resources using CloudFormation \(p. 850\)](#)

Resources created by CloudFormation

Successfully creating the CloudFormation stack creates the following resources in your AWS account:

- Symmetric encryption KMS key for encryption of data managed by RDS Custom.

- Instance profile and associated IAM role for attaching to RDS Custom instances.
- VPC with the CIDR range specified as the CloudFormation parameter. The default value is `10.0.0.0/16`.
- Two private subnets with the CIDR range specified in the parameters, and two different Availability Zones in the AWS Region. The default values for the subnet CIDRs are `10.0.128.0/20` and `10.0.144.0/20`.
- DHCP option set for the VPC with domain name resolution to an Amazon Domain Name System (DNS) server.
- Route table to associate with two private subnets and no access to the internet.
- Network access control list (ACL) to associate with two private subnets and access restricted to HTTPS.
- VPC security group to be associated with the RDS Custom instance. Access is restricted for outbound HTTPS to AWS service endpoints that are required by RDS Custom.
- VPC security group to be associated with VPC endpoints that are created for AWS service endpoints that are required by RDS Custom.
- DB subnet group in which RDS Custom instances are created.
- VPC endpoints for each of the AWS service endpoints that are required by RDS Custom.

Use the following procedures to create the CloudFormation stack for RDS Custom for SQL Server.

Downloading the template file

To download the template file

1. Open the context (right-click) menu for the link [custom-sqlserver-onboard.zip](#) and choose **Save Link As**.
2. Save the file to your computer.

Configuring resources using CloudFormation

To configure resources using CloudFormation

1. Open the CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
2. To start the Create Stack wizard, choose **Create Stack**.

The **Create stack** page appears.

3. For **Prerequisite - Prepare template**, choose **Template is ready**.
4. For **Specify template**, do the following:
 - a. For **Template source**, choose **Upload a template file**.
 - b. For **Choose file**, navigate to and then choose `custom-sqlserver-onboard.json`.
5. Choose **Next**.

The **Specify stack details** page appears.

6. For **Stack name**, enter `rds-custom-sqlserver`.
7. For **Parameters**, do the following:
 - a. To keep the default options, choose **Next**.
 - b. To change options, choose the appropriate CIDR block range for the VPC and two of its subnets, and then choose **Next**.

Read the description of each parameter carefully before changing parameters.

8. On the **Configure stack options** page, choose **Next**.
9. On the **Review rds-custom-sqlserver** page, do the following:
 - a. For **Capabilities**, select the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** check box.
 - b. Choose **Create stack**.

CloudFormation creates the resources that RDS Custom for SQL Server requires. If the stack creation fails, read through the **Events** tab to see which resource creation failed and its status reason.

The **Outputs** tab for this CloudFormation stack in the console should have information about all resources to be passed as parameters for creating an RDS Custom for SQL Server DB instance. Make sure to use the VPC security group and DB subnet group created by CloudFormation for RDS Custom DB instances. By default, RDS tries to attach the default VPC security group, which might not have the access that you need.

Note

When you delete a CloudFormation stack, all of the resources created by the stack are deleted except the KMS key. The KMS key goes into a pending-deletion state and is deleted after 30 days. To keep the KMS key, perform a [CancelKeyDeletion](#) operation during the 30-day grace period.

If you used CloudFormation to create resources, you can skip [Configuring manually \(p. 851\)](#).

Configuring manually

If you choose to configure resources manually, perform the following tasks.

Topics

- [Make sure that you have a symmetric encryption AWS KMS key \(p. 851\)](#)
- [Creating your IAM role and instance profile manually \(p. 852\)](#)
- [Configuring your VPC manually \(p. 856\)](#)

Make sure that you have a symmetric encryption AWS KMS key

A symmetric encryption AWS KMS key is required for RDS Custom. When you create an RDS Custom for SQL Server DB instance, make sure to supply the KMS key identifier. For more information, see [Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server \(p. 860\)](#).

You have the following options:

- If you have an existing KMS key in your AWS account, you can use it with RDS Custom. No further action is necessary.
- If you already created a symmetric encryption KMS key for a different RDS Custom engine, you can reuse the same KMS key. No further action is necessary.
- If you don't have an existing symmetric encryption KMS key in your account, create a KMS key by following the instructions in [Creating keys](#) in the *AWS Key Management Service Developer Guide*.
- If you're creating a CEV or RDS Custom DB instance, and your KMS key is in a different AWS account, make sure to use the AWS CLI. You can't use the AWS console with cross-account KMS keys.

RDS Custom doesn't support AWS-managed KMS keys.

Make sure that the symmetric encryption key that you use gives the AWS Identity and Access Management (IAM) role in your IAM instance profile access to the `kms:Decrypt` and `kms:GenerateDataKey` operations. If you have a new symmetric encryption key in your account, no

changes are required. Otherwise, make sure that your symmetric encryption key's policy can give access to these operations.

[Creating your IAM role and instance profile manually](#)

To use RDS Custom for SQL Server, create an IAM instance profile and IAM role as described following.

To create the IAM instance profile and IAM roles for RDS Custom for SQL Server

1. Create the IAM role named AWSRDSCustomSQLServerInstanceRole with a trust policy that lets Amazon EC2 assume this role.
2. Add an access policy to AWSRDSCustomSQLServerInstanceRole.
3. Create an IAM instance profile for RDS Custom for SQL Server that is named AWSRDSCustomSQLServerInstanceProfile.
4. Add AWSRDSCustomSQLServerInstanceRole to the instance profile.

[Create the AWSRDSCustomSQLServerInstanceRole IAM role](#)

The following example creates the AWSRDSCustomSQLServerInstanceRole role. The trust policy lets Amazon EC2 assume the role.

```
aws iam create-role \
--role-name AWSRDSCustomSQLServerInstanceRole \
--assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": "sts:AssumeRole",
            "Effect": "Allow",
            "Principal": {
                "Service": "ec2.amazonaws.com"
            }
        }
    ]
}'
```

[Add an access policy to AWSRDSCustomSQLServerInstanceRole](#)

When you embed an inline policy in a role, the inline policy is used as part of the role's access (permissions) policy. You create the AWSRDSCustomSQLServerIamRolePolicy policy, which lets Amazon EC2 get and receive messages and perform various actions.

Make sure that the permissions in the access policy aren't restricted by SCPs or permission boundaries associated with the instance profile role.

The following example creates the access policy named AWSRDSCustomSQLServerIamRolePolicy, and adds it to the AWSRDSCustomSQLServerInstanceRole role. This example assumes that the '\$REGION', '\$ACCOUNT_ID', and '\$CUSTOMER_KMS_KEY_ID' variables have been set. '\$CUSTOMER_KMS_KEY_ID' is the ID, not the Amazon Resource Name (ARN), of the KMS key that you defined in [Make sure that you have a symmetric encryption AWS KMS key \(p. 851\)](#).

```
aws iam put-role-policy \
--role-name AWSRDSCustomSQLServerInstanceRole \
--policy-name AWSRDSCustomSQLServerIamRolePolicy \
--policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ssmAgent1",
            "Effect": "Allow",
            "Action": "ssm:DescribeParameters",
            "Resource": "arn:aws:ssm:$REGION:$ACCOUNT_ID/parameters/*"
        }
    ]
}'
```

```

    "Effect": "Allow",
    "Action": [
        "ssm:GetDeployablePatchSnapshotForInstance",
        "ssm>ListAssociations",
        "ssm:PutInventory",
        "ssm:PutConfigurePackageResult",
        "ssm:UpdateInstanceInformation",
        "ssm:GetManifest"
    ],
    "Resource": "*"

            "logs>CreateLogGroup"
        ],
        "Resource": "arn:aws:logs:'$REGION':'$ACCOUNT_ID':log-group:rds-custom-
instance-*"
    },
    {
        "Sid": "cwlOperations2",
        "Effect": "Allow",
        "Action": "logs:DescribeLogGroups",
        "Resource": "arn:aws:logs:'$REGION':'$ACCOUNT_ID':log-group:*

```

```
    ]'  
}'
```

Create your RDS Custom for SQL Server instance profile

Create your instance profile as follows, naming it `AWSRDSCustomSQLServerInstanceProfile`.

```
aws iam create-instance-profile \  
  --instance-profile-name AWSRDSCustomSQLServerInstanceProfile
```

Add `AWSRDSCustomSQLServerInstanceRole` to your RDS Custom for SQL Server instance profile

Add the `AWSRDSCustomInstanceRoleForRdsCustomInstance` role to the `AWSRDSCustomSQLServerInstanceProfile` profile.

```
aws iam add-role-to-instance-profile \  
  --instance-profile-name AWSRDSCustomSQLServerInstanceProfile \  
  --role-name AWSRDSCustomSQLServerInstanceRole
```

Configuring your VPC manually

Your RDS Custom DB instance is in a virtual private cloud (VPC) based on the Amazon VPC service, just like an Amazon EC2 instance or Amazon RDS instance. You provide and configure your own VPC. Thus, you have full control over your instance networking setup.

RDS Custom sends communication from your DB instance to other AWS services. To make sure that RDS Custom can communicate, it validates network connectivity to these services.

Your DB instance communicates with the following AWS services:

- Amazon CloudWatch
- Amazon CloudWatch Logs
- Amazon CloudWatch Events
- Amazon EC2
- Amazon EventBridge
- Amazon S3
- AWS Secrets Manager
- AWS Systems Manager

Make sure that VPC components involved in communication between the DB instance and AWS services are configured with the following requirements:

- The DB instance can make outbound connections on port 443 to other AWS services.
- The VPC allows incoming responses to requests originating from your DB instance.
- Correctly resolve the domain names of endpoints for each AWS service.

If you already configured a VPC for a different RDS Custom engine, you can reuse that VPC and skip this process.

Topics

- [Configure your VPC security group \(p. 857\)](#)
- [Configure endpoints for dependent AWS services \(p. 857\)](#)
- [Configure the instance metadata service \(p. 859\)](#)

Configure your VPC security group

A *security group* acts as a virtual firewall for a VPC instance, controlling both inbound and outbound traffic. An RDS Custom DB instance has a default security group that protects the instance. Make sure that your security group permits traffic between RDS Custom and other AWS services.

To configure your security group for RDS Custom

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc>.
2. Allow RDS Custom to use the default security group, or create your own security group.

For detailed instructions, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).

3. Make sure that your security group permits outbound connections on port 443. RDS Custom needs this port to communicate with dependent AWS services.
4. If you have a private VPC and use VPC endpoints, make sure that the security group associated with the DB instance allows outbound connections on port 443 to VPC endpoints. Also make sure that the security group associated with the VPC endpoint allows inbound connections on port 443 from the DB instance.

If incoming connections aren't allowed, the RDS Custom instance can't connect to the AWS Systems Manager and Amazon EC2 endpoints. For more information, see [Create a Virtual Private Cloud endpoint](#) in the *AWS Systems Manager User Guide*.

For more information about security groups, see [Security groups for your VPC](#) in the *Amazon VPC Developer Guide*.

Configure endpoints for dependent AWS services

Make sure that your VPC allows outbound traffic to the following AWS services with which the DB instance communicates:

- Amazon CloudWatch
- Amazon CloudWatch Logs
- Amazon CloudWatch Events
- Amazon EC2
- Amazon EventBridge
- Amazon S3
- AWS Secrets Manager
- AWS Systems Manager

We recommend that you add endpoints for every service to your VPC using the following instructions. However, you can use any solution that lets your VPC communicate with AWS service endpoints. For example, you can use Network Address Translation (NAT) or AWS Direct Connect.

To configure endpoints for AWS services with which RDS Custom works

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. On the navigation bar, use the Region selector to choose the AWS Region.
3. In the navigation pane, choose **Endpoints**. In the main pane, choose **Create Endpoint**.
4. For **Service category**, choose **AWS services**.
5. For **Service Name**, choose the endpoint shown in the table.

6. For **VPC**, choose your VPC.
7. For **Subnets**, choose a subnet from each Availability Zone to include.

The VPC endpoint can span multiple Availability Zones. AWS creates an elastic network interface for the VPC endpoint in each subnet that you choose. Each network interface has a Domain Name System (DNS) host name and a private IP address.
8. For **Security group**, choose or create a security group.

You can use security groups to control access to your endpoint, much as you use a firewall. For more information about security groups, see [Security groups for your VPC](#) in the *Amazon VPC User Guide*.
9. Optionally, you can attach a policy to the VPC endpoint. Endpoint policies can control access to the AWS service to which you are connecting. The default policy allows all requests to pass through the endpoint. If you're using a custom policy, make sure that requests from the DB instance are allowed in the policy.
10. Choose **Create endpoint**.

The following table explains how to find the list of endpoints that your VPC needs for outbound communications.

Service	Endpoint format	Notes and links
AWS Systems Manager	Use the following endpoint formats: <ul style="list-style-type: none">• <code>ssm.region.amazonaws.com</code>• <code>ssmmessages.region.amazonaws.com</code>	For the list of endpoints in each Region, see AWS Systems Manager endpoints and quotas in the <i>Amazon Web Services General Reference</i> .
AWS Secrets Manager	Use the endpoint format <code>secretsmanager.region.amazonaws.com</code> .	For the list of endpoints in each Region, see AWS Secrets Manager endpoints and quotas in the <i>Amazon Web Services General Reference</i> .
Amazon CloudWatch	Use the following endpoint formats: <ul style="list-style-type: none">• For CloudWatch metrics, use <code>monitoring.region.amazonaws.com</code>• For CloudWatch Events, use <code>events.region.amazonaws.com</code>• For CloudWatch Logs, use <code>logs.region.amazonaws.com</code>	For the list of endpoints in every Region, see: <ul style="list-style-type: none">• Amazon CloudWatch endpoints and quotas in the Amazon Web Services General Reference• Amazon CloudWatch Logs endpoints and quotas in the Amazon Web Services General Reference• Amazon CloudWatch Events endpoints and quotas in the Amazon Web Services General Reference
Amazon EC2	Use the following endpoint formats: <ul style="list-style-type: none">• <code>ec2.region.amazonaws.com</code>• <code>ec2messages.region.amazonaws.com</code>	For the list of endpoints in each Region, see Amazon Elastic Compute Cloud endpoints and quotas in the <i>Amazon Web Services General Reference</i> .
Amazon S3	Use the endpoint format <code>s3.region.amazonaws.com</code> .	For the list of endpoints in each Region, see Amazon Simple Storage Service endpoints and quotas in the <i>Amazon Web Services General Reference</i> . To learn more about gateway endpoints for Amazon S3, see Endpoints for

Service	Endpoint format	Notes and links
		<p>Amazon S3 in the <i>Amazon VPC Developer Guide</i>.</p> <p>To learn how to create an access point, see Creating access points in the <i>Amazon VPC Developer Guide</i>.</p> <p>To learn how to create a gateway endpoints for Amazon S3, see Gateway VPC endpoints.</p>

Configure the instance metadata service

Make sure that your instance can do the following:

- Access the instance metadata service using Instance Metadata Service Version 2 (IMDSv2).
- Allow outbound communications through port 80 (HTTP) to the IMDS link IP address.
- Request instance metadata from `http://169.254.169.254`, the IMDSv2 link.

For more information, see [Use IMDSv2](#) in the *Amazon EC2 User Guide for Linux Instances*.

Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server

You can create an RDS Custom DB instance, and then connect to it using AWS Systems Manager or Remote Desktop Protocol (RDP).

Important

Before you can create or connect to an RDS Custom for SQL Server DB instance, make sure to complete the tasks in [Setting up your environment for Amazon RDS Custom for SQL Server \(p. 847\)](#).

You can tag RDS Custom DB instances when you create them, but don't create or modify the AWSRDSCustom tag that's required for RDS Custom automation. For more information, see [Tagging RDS Custom for SQL Server resources \(p. 875\)](#).

The first time that you create an RDS Custom for SQL Server DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

Topics

- [Creating an RDS Custom for SQL Server DB instance \(p. 860\)](#)
- [RDS Custom service-linked role \(p. 863\)](#)
- [Connecting to your RDS Custom DB instance using AWS Systems Manager \(p. 863\)](#)
- [Connecting to your RDS Custom DB instance using RDP \(p. 865\)](#)

Creating an RDS Custom for SQL Server DB instance

Create an Amazon RDS Custom for SQL Server DB instance using either the AWS Management Console or the AWS CLI. The procedure is similar to the procedure for creating an Amazon RDS DB instance.

For more information, see [Creating an Amazon RDS DB instance \(p. 230\)](#).

Console

To create an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose **Create database**.
4. Choose **Standard create** for the database creation method.
5. For **Engine options**, choose **Microsoft SQL Server** for the engine type.
6. For **Database management type**, choose **Amazon RDS Custom**.
7. In the **Edition** section, choose the DB engine edition that you want to use. For RDS Custom for SQL Server, the choices are Enterprise, Standard, and Web.
8. For **Database version**, keep the SQL Server 2019 default value.
9. For **Templates**, choose **Production**.
10. In the **Settings** section, enter a unique name for the **DB instance identifier**.
11. To enter your master password, do the following:
 - a. In the **Settings** section, open **Credential Settings**.
 - b. Clear the **Auto generate a password** check box.

- c. Change the **Master username** value and enter the same password in **Master password** and **Confirm password**.

By default, the new RDS Custom DB instance uses an automatically generated password for the master user.

12. In the **DB instance size** section, choose a value for **DB instance class**.

For supported classes, see [DB instance class support for RDS Custom for SQL Server \(p. 845\)](#).

13. Choose **Storage** settings.

14. For **RDS Custom security**, do the following:

- a. For **IAM instance profile**, choose the instance profile for your RDS Custom for SQL Server DB instance.

The IAM instance profile must begin with AWSRDSCustom, for example *AWSRDSCustomInstanceProfileForRdsCustomInstance*.

- b. For **Encryption**, choose **Enter a key ARN** to list the available AWS KMS keys. Then choose your key from the list.

An AWS KMS key is required for RDS Custom. For more information, see [Make sure that you have a symmetric encryption AWS KMS key \(p. 851\)](#).

15. For the remaining sections, specify your preferred RDS Custom DB instance settings. For information about each setting, see [Settings for DB instances \(p. 237\)](#). The following settings don't appear in the console and aren't supported:

- **Processor features**
- **Storage autoscaling**
- **Availability & durability**
- **Password and Kerberos authentication** option in **Database authentication** (only **Password authentication** is supported)
- **Database options** group in **Additional configuration**
- **Performance Insights**
- **Log exports**
- **Enable auto minor version upgrade**
- **Deletion protection**

Backup retention period is supported, but you can't choose **0 days**.

16. Choose **Create database**.

The **View credential details** button appears on the **Databases** page.

To view the master user name and password for the RDS Custom DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it. To change the master user password after the RDS Custom DB instance is available, modify the DB instance. For more information about modifying a DB instance, see [Managing an Amazon RDS Custom for SQL Server DB instance \(p. 868\)](#).

17. Choose **Databases** to view the list of RDS Custom DB instances.

18. Choose the RDS Custom DB instance that you just created.

On the RDS console, the details for the new RDS Custom DB instance appear:

- The DB instance has a status of **creating** until the RDS Custom DB instance is created and ready for use. When the state changes to **available**, you can connect to the DB instance. Depending on the instance class and storage allocated, it can take several minutes for the new DB instance to be available.
- **Role** has the value **Instance (RDS Custom)**.
- **RDS Custom automation mode** has the value **Full automation**. This setting means that the DB instance provides automatic monitoring and instance recovery.

AWS CLI

You create an RDS Custom DB instance by using the [create-db-instance](#) AWS CLI command.

The following options are required:

- `--db-instance-identifier`
- `--db-instance-class` (for a list of supported instance classes, see [DB instance class support for RDS Custom for Oracle \(p. 766\)](#))
- `--engine` (`custom-sqlserver-ee`, `custom-sqlserver-se`, or `custom-sqlserver-web`)
- `--kms-key-id`
- `--custom-iam-instance-profile`

The following example creates an RDS Custom for SQL Server DB instance named `my-custom-instance`. The backup retention period is 3 days.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --engine custom-sqlserver-ee \
    --engine-version 15.00.4073.23.v1 \
    --db-instance-identifier my-custom-instance \
    --db-instance-class db.m5.xlarge \
    --allocated-storage 20 \
    --db-subnet-group mydbsubnetgroup \
    --master-username myuser \
    --master-user-password mypassword \
    --backup-retention-period 3 \
    --no-multi-az \
    --port 8200 \
    --license-model license-included \
    --kms-key-id mykmskey \
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
```

For Windows:

```
aws rds create-db-instance ^
    --engine custom-sqlserver-ee ^
    --engine-version 15.00.4073.23.v1 ^
    --db-instance-identifier my-custom-instance ^
    --db-instance-class db.m5.xlarge ^
    --allocated-storage 20 ^
    --db-subnet-group mydbsubnetgroup ^
    --master-username myuser ^
```

```
--master-user-password mypassword ^
--backup-retention-period 3 ^
--no-multi-az ^
--port 8200 ^
--license-model license-included ^
--kms-key-id mykmskey ^
--custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
```

Get details about your instance by using the `describe-db-instances` command.

```
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The following partial output shows the engine, parameter groups, and other information.

```
{
    "DBInstances": [
        {
            "PendingModifiedValues": {},
            "Engine": "custom-sqlserver-ee",
            "MultiAZ": false,
            "DBSecurityGroups": [],
            "DBParameterGroups": [
                {
                    "DBParameterGroupName": "default.custom-sqlserver-ee-15",
                    "ParameterApplyStatus": "in-sync"
                }
            ],
            "AutomationMode": "full",
            "DBInstanceIdentifier": "my-custom-instance",
            "TagList": []
        }
    ]
}
```

RDS Custom service-linked role

A *service-linked role* gives Amazon RDS Custom access to resources in your AWS account. It makes using RDS Custom easier because you don't have to manually add the necessary permissions. RDS Custom defines the permissions of its service-linked roles, and unless defined otherwise, only RDS Custom can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

When you create an RDS Custom DB instance, both the Amazon RDS and RDS Custom service-linked roles are created (if they don't already exist) and used. For more information, see [Using service-linked roles for Amazon RDS \(p. 2089\)](#).

The first time that you create an RDS Custom for SQL Server DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

Connecting to your RDS Custom DB instance using AWS Systems Manager

After you create your RDS Custom DB instance, you can connect to it using AWS Systems Manager Session Manager. Session Manager is a Systems Manager capability that you can use to manage Amazon EC2 instances through a browser-based shell or through the AWS CLI. For more information, see [AWS Systems Manager Session Manager](#).

Console

To connect to your DB instance using Session Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose **Configuration**.
4. Note the **Resource ID** value for your DB instance. For example, the resource ID might be db-ABCDEFHIJKLMNOPQRS0123456.
5. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
6. In the navigation pane, choose **Instances**.
7. Look for the name of your EC2 instance, and then choose the instance ID associated with it. For example, the instance ID might be i-abcdefhijklm01234.
8. Choose **Connect**.
9. Choose **Session Manager**.
10. Choose **Connect**.

A window opens for your session.

AWS CLI

You can connect to your RDS Custom DB instance using the AWS CLI. This technique requires the Session Manager plugin for the AWS CLI. To learn how to install the plugin, see [Install the Session Manager plugin for the AWS CLI](#).

To find the DB resource ID of your RDS Custom DB instance, use [describe-db-instances](#).

```
aws rds describe-db-instances \
--query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
--output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is db-.

```
db-ABCDEFGHIJKLMNOPQRS0123456
```

To find the EC2 instance ID of your DB instance, use `aws ec2 describe-instances`. The following example uses db-ABCDEFGHIJKLMNOPQRS0123456 for the resource ID.

```
aws ec2 describe-instances \
--filters "Name>tag:Name,Values=db-ABCDEFGHIJKLMNOPQRS0123456" \
--output text \
--query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefhijklm01234
```

Use the `aws ssm start-session` command, supplying the EC2 instance ID in the `--target` parameter.

```
aws ssm start-session --target "i-abcdefhijklm01234"
```

A successful connection looks like the following.

```
Starting session with SessionId: yourid-abcdefghijklm1234
[ssm-user@ip-123-45-67-89 bin]$
```

Connecting to your RDS Custom DB instance using RDP

After you create your RDS Custom DB instance, you can connect to this instance using an RDP client. The procedure is the same as for connecting to an Amazon EC2 instance. For more information, see [Connect to your Windows instance](#).

To connect to the DB instance, you need the key pair associated with the instance. RDS Custom creates the key pair for you. The pair name uses the prefix do-not-delete-rds-custom-*DBInstanceIdentifier*. AWS Secrets Manager stores your private key as a secret.

Complete the task in the following steps:

1. [Configure your DB instance to allow RDP connections \(p. 865\)](#).
2. [Retrieve your secret key \(p. 866\)](#).
3. [Connect to your EC2 instance using the RDP utility \(p. 867\)](#).

Configure your DB instance to allow RDP connections

To allow RDP connections, configure your VPC security group and set a firewall rule on the host.

Configure your VPC security group

Make sure that the VPC security group associated with your DB instance permits inbound connections on port 3389 for Transmission Control Protocol (TCP). To learn how to configure your VPC security group, see [Configure your VPC security group \(p. 857\)](#).

Set the firewall rule on the host

To permit inbound connections on port 3389 for TCP, set a firewall rule on the host. The following examples show how to do this.

We recommend that you use the specific -Profile value: Public, Private, or Domain. Using Any refers to all three values. You can also specify a combination of values separated by a comma. For more information about setting firewall rules, see [Set-NetFirewallRule](#) in the Microsoft documentation.

To use Systems Manager Session Manager to set a firewall rule

1. Connect to Session Manager as shown in [Connecting to your RDS Custom DB instance using AWS Systems Manager \(p. 863\)](#).
2. Run the following command.

```
Set-NetFirewallRule -DisplayName "Remote Desktop - User Mode (TCP-In)" -Direction Inbound -LocalAddress Any -Profile Any
```

To use Systems Manager CLI commands to set a firewall rule

1. Use the following command to open RDP on the host.

```
OPEN_RDP_COMMAND_ID=$(aws ssm send-command --region $AWS_REGION \
--instance-ids $RDS_CUSTOM_INSTANCE_EC2_ID \
```

```
--document-name "AWS-RunPowerShellScript" \
--parameters '{"commands":["Set-NetFirewallRule -DisplayName \"Remote Desktop - User Mode (TCP-In)\" -Direction Inbound -LocalAddress Any -Profile Any"]}' \
--comment "Open RDP port" | jq -r ".Command.CommandId")
```

2. Use the command ID returned in the output to get the status of the previous command. To use the following query to return the command ID, make sure that you have the jq plug-in installed.

```
aws ssm list-commands \
--region $AWS_REGION \
--command-id $OPEN_RDP_COMMAND_ID
```

Retrieve your secret key

Retrieve your secret key using either AWS Management Console or the AWS CLI.

Console

To retrieve the secret key

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose the **Configuration** tab.
4. Note the **DB instance ID** for your DB instance, for example, *my-custom-instance*.
5. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
6. In the navigation pane, choose **Instances**.
7. Look for the name of your EC2 instance, and then choose the instance ID associated with it.
In this example, the instance ID is *i-abcdefgijklm01234*.
8. In **Details**, find **Key pair name**. The pair name includes the DB identifier. In this example, the pair name is *do-not-delete-rds-custom-my-custom-instance-0d726c*.
9. In the instance summary, find **Public IPv4 DNS**. For the example, the public DNS might be *ec2-12-345-678-901.us-east-2.compute.amazonaws.com*.
10. Open the AWS Secrets Manager console at <https://console.aws.amazon.com/secretsmanager/>.
11. Choose the secret that has the same name as your key pair.
12. Choose **Retrieve secret value**.

AWS CLI

To retrieve the private key

1. Get the list of your RDS Custom DB instances by calling the `aws rds describe-db-instances` command.

```
aws rds describe-db-instances \
--query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
--output text
```

2. Choose the DB instance identifier from the sample output, for example *do-not-delete-rds-custom-my-custom-instance*.
3. Find the EC2 instance ID of your DB instance by calling the `aws ec2 describe-instances` command. The following example uses the EC2 instance name to describe the DB instance.

```
aws ec2 describe-instances \
--filters "Name=tag:Name,Values=do-not-delete-rds-custom-my-custom-instance" \
--output text \
--query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefghijklm01234
```

4. Find the key name by specifying the EC2 instance ID, as shown in the following example.

```
aws ec2 describe-instances \
--instance-ids i-abcdefghijklm01234 \
--output text \
--query 'Reservations[*].Instances[*].KeyName'
```

The following sample output shows the key name, which uses the prefix do-not-delete-rds-custom-*DBInstanceIdentifier*.

```
do-not-delete-rds-custom-my-custom-instance-0d726c
```

Connect to your EC2 instance using the RDP utility

Follow the procedure in [Connect to your Windows instance using RDP](#) in the *Amazon EC2 User Guide for Windows Instances*. This procedure assumes that you created a .pem file that contains your private key.

Managing an Amazon RDS Custom for SQL Server DB instance

Amazon RDS Custom for SQL Server supports a subset of the usual management tasks for Amazon RDS DB instances. Following, you can find instructions for the supported RDS Custom for SQL Server management tasks using the AWS Management Console and the AWS CLI.

Topics

- [Working with high availability features for RDS Custom for SQL Server \(p. 868\)](#)
- [Pausing and resuming RDS Custom automation \(p. 868\)](#)
- [Modifying an RDS Custom for SQL Server DB instance \(p. 872\)](#)
- [Modifying the storage for an RDS Custom for SQL Server DB instance \(p. 873\)](#)
- [Support for Transparent Data Encryption \(p. 875\)](#)
- [Tagging RDS Custom for SQL Server resources \(p. 875\)](#)
- [Deleting an RDS Custom for SQL Server DB instance \(p. 875\)](#)

Working with high availability features for RDS Custom for SQL Server

To support replication between RDS Custom for SQL Server instances, you can configure high availability (HA) with Always On Availability Groups (AGs). The primary DB instance automatically synchronizes data to the standby instances.

You can configure your high availability environment in the following ways:

- Configure standby instances in different Availability Zones (AZs) to be resilient to AZ failures.
- Place your standby databases in mounted or read-only mode.
- Fail over or switch over from the primary database to a standby database with no data loss.
- Migrate data by configuring high availability for your on-premises instance, and then failing over or switching over to the RDS Custom standby database.

To learn how to configure high availability, see the blog post [Configure high availability with Always On Availability Groups on Amazon RDS Custom for SQL Server](#). You can perform the following tasks:

- Use a virtual private network (VPN) tunnel to encrypt data in transit for your high availability instances. Encryption in transit isn't configured automatically by RDS Custom.
- Configure Always On AGs to monitor your high availability instances.
- Allow the observer to perform automatic failover when necessary conditions are met.

You can also use other encryption technology, such as Secure Sockets Layer (SSL), to encrypt data in transit.

You're responsible for configuring VPC flow logs and CloudWatch alarms to monitor traffic mirroring to prevent data leakage.

Pausing and resuming RDS Custom automation

RDS Custom automatically provides monitoring and instance recovery for an RDS Custom for SQL Server DB instance. If you need to customize the instance, do the following:

1. Pause RDS Custom automation for a specified period. The pause ensures that your customizations don't interfere with RDS Custom automation.
2. Customize the RDS Custom for SQL Server DB instance as needed.
3. Do either of the following:
 - Resume automation manually.
 - Wait for the pause period to end. In this case, RDS Custom resumes monitoring and instance recovery automatically.

Important

Pausing and resuming automation are the only supported automation tasks when modifying an RDS Custom for SQL Server DB instance.

[Console](#)

To pause or resume RDS Custom automation

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **RDS Custom automation mode**, choose one of the following options:
 - **Paused** pauses the monitoring and instance recovery for the RDS Custom DB instance. Enter the pause duration that you want (in minutes) for **Automation mode duration**. The minimum value is 60 minutes (default). The maximum value is 1,440 minutes.
 - **Full automation** resumes automation.
5. Choose **Continue** to check the summary of modifications.

A message indicates that RDS Custom will apply the changes immediately.
6. If your changes are correct, choose **Modify DB instance**. Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

On the RDS console, the details for the modification appear. If you paused automation, the **Status** of your RDS Custom DB instance indicates **Automation paused**.
7. (Optional) In the navigation pane, choose **Databases**, and then your RDS Custom DB instance.

In the **Summary** pane, **RDS Custom automation mode** indicates the automation status. If automation is paused, the value is **Paused**. **Automation resumes in num minutes**.

[AWS CLI](#)

To pause or resume RDS Custom automation, use the [modify-db-instance](#) AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. Control the automation mode with the following parameters:

- `--automation-mode` specifies the pause state of the DB instance. Valid values are `all-paused`, which pauses automation, and `full`, which resumes it.
- `--resume-full-automation-mode-minutes` specifies the duration of the pause. The default value is 60 minutes.

Note

Regardless of whether you specify `--no-apply-immediately` or `--apply-immediately`, RDS Custom applies modifications asynchronously as soon as possible.

In the command response, `ResumeFullAutomationModeTime` indicates the resume time as a UTC timestamp. When the automation mode is all-paused, you can use `modify-db-instance` to resume automation mode or extend the pause period. No other `modify-db-instance` options are supported.

The following example pauses automation for `my-custom-instance` for 90 minutes.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance \
  --automation-mode all-paused \
  --resume-full-automation-mode-minutes 90
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier my-custom-instance ^
  --automation-mode all-paused ^
  --resume-full-automation-mode-minutes 90
```

The following example extends the pause duration for an extra 30 minutes. The 30 minutes is added to the original time shown in `ResumeFullAutomationModeTime`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance \
  --automation-mode all-paused \
  --resume-full-automation-mode-minutes 30
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier my-custom-instance ^
  --automation-mode all-paused ^
  --resume-full-automation-mode-minutes 30
```

The following example resumes full automation for `my-custom-instance`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance \
  --automation-mode full \
```

For Windows:

```
aws rds modify-db-instance ^
```

```
--db-instance-identifier my-custom-instance ^
--automation-mode full
```

In the following partial sample output, the pending AutomationMode value is full.

```
{
    "DBInstance": {
        "PubliclyAccessible": true,
        "MasterUsername": "admin",

```

Modifying an RDS Custom for SQL Server DB instance

Modifying an RDS Custom for SQL Server DB instance is similar to doing this for Amazon RDS, but the changes that you can make are limited to the following:

- Changing the DB instance class
- Changing the backup retention period and backup window
- Changing the maintenance window
- Upgrading the DB engine version when a new version becomes available

The following limitations apply to modifying an RDS Custom for SQL Server DB instance:

- Multi-AZ deployments aren't supported.
- Custom DB option and parameter groups aren't supported.
- Any storage volumes that you attach manually to your RDS Custom DB instance are outside the support perimeter.

For more information, see [RDS Custom support perimeter and unsupported configurations \(p. 891\)](#).

Console

To modify an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Make the following changes as needed:
 - a. For **DB engine version**, choose the new version.
 - b. Change the value for **DB instance class**. For supported classes, see [DB instance class support for RDS Custom for SQL Server \(p. 845\)](#)
 - c. Change the value for **Backup retention period**.
 - d. For **Backup window**, set values for the **Start time** and **Duration**.
 - e. For **DB instance maintenance window**, set values for the **Start day**, **Start time**, and **Duration**.
6. Choose **Continue**.
7. Choose **Apply immediately** or **Apply during the next scheduled maintenance window**.
8. Choose **Modify DB instance**.

AWS CLI

To modify an RDS Custom for SQL Server DB instance, use the `modify-db-instance` AWS CLI command. Set the following parameters as needed:

- `--db-instance-class` – For supported classes, see [DB instance class support for RDS Custom for SQL Server \(p. 845\)](#)

- `--engine-version` – The version number of the database engine to which you're upgrading.
- `--backup-retention-period` – How long to retain automated backups, from 0–35 days.
- `--preferred-backup-window` – The daily time range during which automated backups are created.
- `--preferred-maintenance-window` – The weekly time range (in UTC) during which system maintenance can occur.
- `--apply-immediately` – Use `--apply-immediately` to apply the storage changes immediately.
Or use `--no-apply-immediately` (the default) to apply the changes during the next maintenance window.

Modifying the storage for an RDS Custom for SQL Server DB instance

Modifying storage for an RDS Custom for SQL Server DB instance is similar to modifying storage for an Amazon RDS DB instance, but you can only do the following:

- Increase the allocated storage size.
- Change the storage type. For example, you can modify the storage type from io1 to gp2, or gp2 to io1.
- Change the provisioned IOPS, if you're using the volume types that supports provisioned IOPS, such as io1.

The following limitations apply to modifying the storage for an RDS Custom for SQL Server DB instance:

- The minimum allocated storage size for RDS Custom for SQL Server is 20 GiB, and the maximum supported storage size is 16 TiB.
- As with Amazon RDS, you can't decrease the allocated storage. This is a limitation of Amazon Elastic Block Store (Amazon EBS) volumes. For more information, see [Working with storage for Amazon RDS DB instances \(p. 410\)](#)
- Storage autoscaling isn't supported for RDS Custom for SQL Server DB instances.
- Any storage volumes that you manually attach to your RDS Custom DB instance are not considered for storage scaling. Only the RDS-provided default data volumes, i.e., the D drive, are considered for storage scaling.

For more information, see [RDS Custom support perimeter and unsupported configurations \(p. 891\)](#).

- Scaling storage usually doesn't cause any outage or performance degradation of the DB instance. After you modify the storage size for a DB instance, the status of the DB instance is **storage-optimization**.
- Storage optimization can take several hours. You can't make further storage modifications for either six (6) hours or until storage optimization has completed on the instance, whichever is longer. For more information, see [Working with storage for Amazon RDS DB instances \(p. 410\)](#)

For more information about storage, see [Amazon RDS DB instance storage \(p. 64\)](#).

For general information about storage modification, see [Working with storage for Amazon RDS DB instances \(p. 410\)](#).

Console

To modify the storage for an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Make the following changes as needed:
 - a. Enter a new value for **Allocated storage**. It must be greater than the current value, and from 20 GiB–16 TiB.
 - b. Change the value for **Storage type**. You can use available storage types like General Purpose (gp2) or Provisioned IOPS (io1) storage.
 - c. If you are specifying volume types that support provisioned IOPS, you can define the **Provisioned IOPS** value.
6. Choose **Continue**.
7. Choose **Apply immediately** or **Apply during the next scheduled maintenance window**.
8. Choose **Modify DB instance**.

AWS CLI

To modify the storage for an RDS Custom for SQL Server DB instance, use the [modify-db-instance](#) AWS CLI command. Set the following parameters as needed:

- **--allocated-storage** – Amount of storage to be allocated for the DB instance, in gibibytes. It must be greater than the current value, and from 20–16,384 GiB.
- **--storage-type** – The storage type, for example, gp2 or io1.
- **--iops** – Provisioned IOPS for the DB instance. You can specify this only for storage types that support provisioned IOPS, like io1.
- **--apply-immediately** – Use **--apply-immediately** to apply the storage changes immediately.

Or use **--no-apply-immediately** (the default) to apply the changes during the next maintenance window.

The following example changes the storage size of my-custom-instance to 200 GiB, storage type to io1, and Provisioned IOPS to 3000.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance \
  --storage-type io1 \
  --iops 3000 \
  --allocated-storage 200 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier my-custom-instance ^
  --storage-type io1 ^
  --iops 3000 ^
  --allocated-storage 200 ^
  --apply-immediately
```

Support for Transparent Data Encryption

RDS Custom supports Transparent Data Encryption (TDE) for RDS Custom for SQL Server DB instances.

However, you can't enable TDE using an option in a custom option group as you can in RDS for SQL Server. You turn on TDE manually. For information about Transparent Data Encryption for SQL Server, see [Transparent Data Encryption \(TDE\)](#) in the Microsoft documentation.

Tagging RDS Custom for SQL Server resources

You can tag RDS Custom resources as with Amazon RDS resources, but with some important differences:

- Don't create or modify the AWSRDSCustom tag that's required for RDS Custom automation. If you do, you might break the automation.
- Tags added to RDS Custom DB instances during creation are propagated to all other related RDS Custom resources.
- Tags aren't propagated when you add them to RDS Custom resources after DB instance creation.

For general information about resource tagging, see [Tagging Amazon RDS resources \(p. 392\)](#).

Deleting an RDS Custom for SQL Server DB instance

To delete an RDS Custom DB instance, do the following:

- Provide the name of the DB instance.
- Clear the option to take a final DB snapshot of the DB instance.
- Choose or clear the option to retain automated backups.

You can delete an RDS Custom DB instance using the console or the CLI. The time required to delete the DB instance can vary depending on the backup retention period (that is, how many backups to delete) and how much data is deleted.

Console

To delete an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance that you want to delete. RDS Custom DB instances show the role **Instance (RDS Custom)**.
3. For **Actions**, choose **Delete**.
4. To retain automated backups, choose **Retain automated backups**.
5. Enter **delete me** in the box.
6. Choose **Delete**.

AWS CLI

You delete an RDS Custom DB instance by using the `delete-db-instance` AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. The remaining parameters are the same as for an Amazon RDS DB instance, with the following exceptions:

- `--skip-final-snapshot` is required.
- `--no-skip-final-snapshot` isn't supported.

- `--final-db-snapshot-identifier` isn't supported.

The following example deletes the RDS Custom DB instance named `my-custom-instance`, and retains automated backups.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
  --db-instance-identifier my-custom-instance \
  --skip-final-snapshot \
  --no-delete-automated-backups
```

For Windows:

```
aws rds delete-db-instance ^
  --db-instance-identifier my-custom-instance ^
  --skip-final-snapshot ^
  --no-delete-automated-backups
```

Backing up and restoring an Amazon RDS Custom for SQL Server DB instance

Like Amazon RDS, RDS Custom creates and saves automated backups of your RDS Custom for SQL Server DB instance during the backup window of your DB instance. You can also back up your DB instance manually.

The procedure is identical to taking a snapshot of an Amazon RDS DB instance. The first snapshot of an RDS Custom DB instance contains the data for the full DB instance. Subsequent snapshots are incremental.

Restore DB snapshots using either the AWS Management Console or the AWS CLI.

Topics

- [Creating an RDS Custom for SQL Server snapshot \(p. 877\)](#)
- [Restoring from an RDS Custom for SQL Server DB snapshot \(p. 878\)](#)
- [Restoring an RDS Custom for SQL Server instance to a point in time \(p. 879\)](#)
- [Deleting an RDS Custom for SQL Server snapshot \(p. 882\)](#)
- [Deleting RDS Custom for SQL Server automated backups \(p. 883\)](#)

Creating an RDS Custom for SQL Server snapshot

RDS Custom for SQL Server creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. When you create a snapshot, specify which RDS Custom for SQL Server DB instance to back up. Give your snapshot a name so you can restore from it later.

When you create a snapshot, RDS Custom for SQL Server creates an Amazon EBS snapshot for every volume attached to the DB instance. RDS Custom for SQL Server uses the EBS snapshot of the root volume to register a new Amazon Machine Image (AMI). To make snapshots easy to associate with a specific DB instance, they're tagged with `DBSnapshotIdentifier`, `DBiResourceId`, and `VolumeType`.

Creating a DB snapshot results in a brief I/O suspension. This suspension can last from a few seconds to a few minutes, depending on the size and class of your DB instance. The snapshot creation time varies with the size of your database. Because the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects snapshot creation time. To learn more about creating snapshots, see [Creating a DB snapshot \(p. 448\)](#).

Create an RDS Custom for SQL Server snapshot using the console or the AWS CLI.

Console

To create an RDS Custom snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. In the list of RDS Custom DB instances, choose the instance for which you want to take a snapshot.
4. For **Actions**, choose **Take snapshot**.

The **Take DB snapshot** window appears.

5. For **Snapshot name**, enter the name of the snapshot.
6. Choose **Take snapshot**.

AWS CLI

You create a snapshot of an RDS Custom DB instance by using the [create-db-snapshot](#) AWS CLI command.

Specify the following options:

- `--db-instance-identifier` – Identifies which RDS Custom DB instance you are going to back up
- `--db-snapshot-identifier` – Names your RDS Custom snapshot so you can restore from it later

In this example, you create a DB snapshot called *my-custom-snapshot* for an RDS Custom DB instance called *my-custom-instance*.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
  --db-instance-identifier my-custom-instance \
  --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds create-db-snapshot ^
  --db-instance-identifier my-custom-instance ^
  --db-snapshot-identifier my-custom-snapshot
```

Restoring from an RDS Custom for SQL Server DB snapshot

When you restore an RDS Custom for SQL Server DB instance, you provide the name of the DB snapshot and a name for the new instance. You can't restore from a snapshot to an existing RDS Custom DB instance. A new RDS Custom for SQL Server DB instance is created when you restore.

The restore process differs in the following ways from restore in Amazon RDS:

- Before restoring a snapshot, RDS Custom for SQL Server backs up existing configuration files. These files are available on the restored instance in the directory `/rdsdbdata/config/backup`. RDS Custom for SQL Server restores the DB snapshot with default parameters and overwrites the previous database configuration files with existing ones. Thus, the restored instance doesn't preserve custom parameters and changes to database configuration files.
- The restored database has the same name as in the snapshot. You can't specify a different name.

Console

To restore an RDS Custom DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore DB instance** page, for **DB instance identifier**, enter the name for your restored RDS Custom DB instance.

6. Choose Restore DB instance.

AWS CLI

You restore an RDS Custom DB snapshot by using the [restore-db-instance-from-db-snapshot](#) AWS CLI command.

If the snapshot you are restoring from is for a private DB instance, make sure to specify both the correct db-subnet-group-name and no-publicly-accessible. Otherwise, the DB instance defaults to publicly accessible. The following options are required:

- db-snapshot-identifier – Identifies the snapshot from which to restore
- db-instance-identifier – Specifies the name of the RDS Custom DB instance to create from the DB snapshot
- custom-iam-instance-profile – Specifies the instance profile associated with the underlying Amazon EC2 instance of an RDS Custom DB instance.

The following code restores the snapshot named my-custom-snapshot for my-custom-instance.

Example

For Linux, macOS, or Unix:

```
aws restore-db-instance-from-db-snapshot \
--db-snapshot-identifier my-custom-snapshot \
--db-instance-identifier my-custom-instance \
--custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
--no-publicly-accessible
```

For Windows:

```
aws restore-db-instance-from-db-snapshot ^
--db-snapshot-identifier my-custom-snapshot ^
--db-instance-identifier my-custom-instance ^
--custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
--no-publicly-accessible
```

Restoring an RDS Custom for SQL Server instance to a point in time

You can restore a DB instance to a specific point in time (PITR), creating a new DB instance. To support PITR, your DB instances must have backup retention set to a nonzero value.

The latest restorable time for an RDS Custom for SQL Server DB instance depends on several factors, but is typically within 5 minutes of the current time. To see the latest restorable time for a DB instance, use the AWS CLI [describe-db-instances](#) command and look at the value returned in the LatestRestorableTime field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose **Automated backups**.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose **Automated backups** in the Amazon RDS console.

For general information about PITR, see [Restoring a DB instance to a specified time \(p. 499\)](#).

Topics

- [PITR considerations for RDS Custom for SQL Server \(p. 880\)](#)

PITR considerations for RDS Custom for SQL Server

In RDS Custom for SQL Server, PITR differs in the following important ways from PITR in Amazon RDS:

- PITR only restores the databases in the DB instance. It doesn't restore the operating system or files on the C: drive.
- For an RDS Custom for SQL Server DB instance, a database is backed up automatically and is eligible for PITR only under the following conditions:
 - The database is online.
 - Its recovery model is set to FULL.
 - It's writable.
 - It has its physical files on the D: drive.
 - It's not listed in the `rds_pitr_blocked_databases` table. For more information, see [Making databases ineligible for PITR \(p. 880\)](#).
- RDS Custom for SQL Server allows up to 5,000 databases per DB instance. However, the maximum number of databases restored by a PITR operation for an RDS Custom for SQL Server DB instance is 100. The 100 databases are determined by the order of their database ID.

Other databases that aren't part of PITR can be restored from DB snapshots, including the automated backups used for PITR.

- Adding a new database, renaming a database, or restoring a database that is eligible for PITR initiates a snapshot of the DB instance.
- Restored databases have the same name as in the source DB instance. You can't specify a different name.
- `AWSRDSCustomSQLServerIamRolePolicy` requires new permissions. For more information, see [Add an access policy to AWSRDSCustomSQLServerInstanceRole \(p. 852\)](#).
- Time zone changes aren't supported for RDS Custom for SQL Server. If you change the operating system or DB instance time zone, PITR (and other automation) doesn't work.

Making databases ineligible for PITR

You can specify that certain RDS Custom for SQL Server databases aren't part of automated backups and PITR. To do this, put their `database_id` values into a `rds_pitr_blocked_databases` table. Use the following SQL script to create the table.

To create the `rds_pitr_blocked_databases` table

- Run the following SQL script.

```
create table msdb..rds_pitr_blocked_databases
(
    database_id INT NOT NULL,
    database_name SYSNAME NOT NULL,
    db_entry_updated_date datetime NOT NULL DEFAULT GETDATE(),
    db_entry_updated_by SYSNAME NOT NULL DEFAULT CURRENT_USER,
    PRIMARY KEY (database_id)
);
```

For the list of eligible and ineligible databases, see the RI .End file in the RDSCustomForSQLServer/Instances/`DB_instance_resource_ID`/TransactionLogMetadata directory in the Amazon S3 bucket `do-not-delete-rds-custom-$ACCOUNT_ID-$REGION-unique_identifier`. For more information about the RI .End file, see [Transaction logs in Amazon S3 \(p. 881\)](#).

Transaction logs in Amazon S3

The backup retention period determines whether transaction logs for RDS Custom for SQL Server DB instances are automatically extracted and uploaded to Amazon S3. A nonzero value means that automatic backups are created, and that the RDS Custom agent uploads the transaction logs to S3 every 5 minutes.

Transaction log files on S3 are encrypted at rest using the AWS KMS key that you provided when you created your DB instance. For more information, see [Protecting data using server-side encryption](#) in the [Amazon Simple Storage Service User Guide](#).

The transaction logs for each database are uploaded to an S3 bucket named do-not-delete-rds-custom-\$ACCOUNT_ID-\$REGION-unique_identifier. The RDSCustomForSQLServer/Instances/DB_instance_resource_ID directory in the S3 bucket contains two subdirectories:

- TransactionLogs – Contains the transaction logs for each database and their respective metadata.

The transaction log file name follows the pattern *yyyyMMddHHmm.database_id.timestamp*, for example:

```
202110202230.11.1634769287
```

The same file name with the suffix _metadata contains information about the transaction log such as log sequence numbers, database name, and RdsChunkCount. RdsChunkCount determines how many physical files represent a single transaction log file. You might see files with suffixes _0001, _0002, and so on, which mean the physical chunks of a transaction log file. If you want to use a chunked transaction log file, make sure to merge the chunks after downloading them.

Consider a scenario where you have the following files:

- 202110202230.11.1634769287
- 202110202230.11.1634769287_0001
- 202110202230.11.1634769287_0002
- 202110202230.11.1634769287_metadata

The RdsChunkCount is 3. The order for merging the files is the following:

202110202230.11.1634769287, 202110202230.11.1634769287_0001,
202110202230.11.1634769287_0002.

- TransactionLogMetadata – Contains metadata information about each iteration of transaction log extraction.

The RI.End file contains information for all databases that had their transaction logs extracted, and all databases that exist but didn't have their transaction logs extracted. The RI.End file name follows the pattern *yyyyMMddHHmm.RI.End.timestamp*, for example:

```
202110202230.RI.End.1634769281
```

You can restore an RDS Custom for SQL Server DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore an RDS Custom DB instance to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Automated backups**.
3. Choose the RDS Custom DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

The **Restore to point in time** window appears.

5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

If you chose **Custom**, enter the date and time to which you want to restore the instance.

Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

6. For **DB instance identifier**, enter the name of the target restored RDS Custom DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class.
8. Choose **Restore to point in time**.

AWS CLI

You restore a DB instance to a specified time by using the [restore-db-instance-to-point-in-time](#) AWS CLI command to create a new RDS Custom DB instance.

Use one of the following options to specify the backup to restore from:

- `--source-db-instance-identifier mysourcedbinstance`
- `--source-db-instance-resource-id dbinstanceresourceID`
- `--source-db-instance-automated-backups-arn backupARN`

The `custom-iam-instance-profile` option is required.

The following example restores `my-custom-db-instance` to a new DB instance named `my-restored-custom-db-instance`, as of the specified time.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
  --source-db-instance-identifier my-custom-db-instance \
  --target-db-instance-identifier my-restored-custom-db-instance \
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
  --restore-time 2022-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
  --source-db-instance-identifier my-custom-db-instance ^
  --target-db-instance-identifier my-restored-custom-db-instance ^
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
  --restore-time 2022-10-14T23:45:00.000Z
```

Deleting an RDS Custom for SQL Server snapshot

You can delete DB snapshots managed by RDS Custom for SQL Server when you no longer need them. The deletion procedure is the same for both Amazon RDS and RDS Custom DB instances.

The Amazon EBS snapshots for the binary and root volumes remain in your account for a longer time because they might be linked to some instances running in your account or to other RDS Custom for SQL Server snapshots. These EBS snapshots are automatically deleted after they're no longer related to any existing RDS Custom for SQL Server resources (DB instances or backups).

Console

To delete a snapshot of an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete snapshot**.
5. Choose **Delete** on the confirmation page.

AWS CLI

To delete an RDS Custom snapshot, use the AWS CLI command `delete-db-snapshot`.

The following option is required:

- `--db-snapshot-identifier` – The snapshot to be deleted

The following example deletes the `my-custom-snapshot` DB snapshot.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-snapshot \
--db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds delete-db-snapshot ^
--db-snapshot-identifier my-custom-snapshot
```

Deleting RDS Custom for SQL Server automated backups

You can delete retained automated backups for RDS Custom for SQL Server when they are no longer needed. The procedure is the same as the procedure for deleting Amazon RDS backups.

Console

To delete a retained automated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Automated backups**.
3. Choose **Retained**.
4. Choose the retained automated backup that you want to delete.
5. For **Actions**, choose **Delete**.

6. On the confirmation page, enter **delete me** and choose **Delete**.

AWS CLI

You can delete a retained automated backup by using the AWS CLI command [delete-db-instance-automated-backup](#).

The following option is used to delete a retained automated backup:

- **--dbi-resource-id** – The resource identifier for the source RDS Custom DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup by using the AWS CLI command [describe-db-instance-automated-backups](#).

The following example deletes the retained automated backup with source DB instance resource identifier `custom-db-123ABCEXAMPLE`.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
--dbi-resource-id custom-db-123ABCEXAMPLE
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
--dbi-resource-id custom-db-123ABCEXAMPLE
```

Migrating an on-premises database to Amazon RDS Custom for SQL Server

You can use the following process to migrate an on-premises Microsoft SQL Server database to Amazon RDS Custom for SQL Server using native backup and restore:

1. Take a full backup of the database on the on-premises DB instance.
2. Upload the backup file to Amazon S3.
3. Download the backup file from S3 to your RDS Custom for SQL Server DB instance.
4. Restore a database using the downloaded backup file on the RDS Custom for SQL Server DB instance.

This process explains the migration of a database from on-premises to RDS Custom for SQL Server, using native full backup and restore. To reduce the cutover time during the migration process, you might also consider using differential or log backups.

For general information about native backup and restore for RDS for SQL Server, see [Importing and exporting SQL Server databases using native backup and restore \(p. 1099\)](#).

Topics

- [Prerequisites \(p. 885\)](#)
- [Backing up the on-premises database \(p. 885\)](#)
- [Uploading the backup file to Amazon S3 \(p. 886\)](#)
- [Downloading the backup file from Amazon S3 \(p. 886\)](#)
- [Restoring the backup file to the RDS Custom for SQL Server DB instance \(p. 886\)](#)

Prerequisites

Perform the following tasks before migrating the database:

1. Configure Remote Desktop Connection (RDP) for your RDS Custom for SQL Server DB instance. For more information, see [Connecting to your RDS Custom DB instance using RDP \(p. 865\)](#).
2. Configure access to Amazon S3 so you can upload and download the database backup file. For more information, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 \(p. 1153\)](#).

Backing up the on-premises database

You use SQL Server native backup to take a full backup of the database on the on-premises DB instance.

The following example shows a backup of a database called `mydatabase`, with the `COMPRESSION` option specified to reduce the backup file size.

To back up the on-premises database

1. Using SQL Server Management Studio (SSMS), connect to the on-premises SQL Server instance.
2. Run the following T-SQL command.

```
backup database mydatabase to  
disk ='C:\Program Files\Microsoft SQL Server\MSSQL13.MSSQLSERVER\MSSQL\Backup\mydb-  
full-compressed.bak'  
with compression;
```

Uploading the backup file to Amazon S3

You use the AWS Management Console to upload the backup file `mydb-full-compressed.bak` to Amazon S3.

To upload the backup file to S3

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. For **Buckets**, choose the name of the bucket to which you want to upload your backup file.
3. Choose **Upload**.
4. In the **Upload** window, do one of the following:
 - Drag and drop `mydb-full-compressed.bak` to the **Upload** window.
 - Choose **Add file**, choose `mydb-full-compressed.bak`, and then choose **Open**.

Amazon S3 uploads your backup file as an S3 object. When the upload completes, you can see a success message on the **Upload: status** page.

Downloading the backup file from Amazon S3

You use the console to download the backup file from S3 to the RDS Custom for SQL Server DB instance.

To download the backup file from S3

1. Using RDP, connect to your RDS Custom for SQL Server DB instance.
2. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
3. In the **Buckets** list, choose the name of the bucket that contains your backup file.
4. Choose the backup file `mydb-full-compressed.bak`.
5. For **Actions**, choose **Download as**.
6. Open the context (right-click) menu for the link provided, then choose **Save As**.
7. Save `mydb-full-compressed.bak` to the `D:\rdsdbdata\BACKUP` directory.

Restoring the backup file to the RDS Custom for SQL Server DB instance

You use SQL Server native restore to restore the backup file to your RDS Custom for SQL Server DB instance.

In this example, the MOVE option is specified because the data and log file directories are different from the on-premises DB instance.

To restore the backup file

1. Using SSMS, connect to your RDS Custom for SQL Server DB instance.
2. Run the following T-SQL command.

```
restore database mydatabase from disk='D:\rdsdbdata\BACKUP\mydb-full-compressed.bak'  
with move 'mydatabase' to 'D:\rdsdbdata\DATA\mydatabase.mdf',  
move 'mydatabase_log' to 'D:\rdsdbdata\DATA\mydatabase_log.ldf';
```

Upgrading a DB instance for Amazon RDS Custom for SQL Server

You can upgrade an Amazon RDS Custom for SQL Server DB instance by modifying it to use a new DB engine version, the same as you do for Amazon RDS.

The same limitations for upgrading an RDS Custom for SQL Server DB instance apply as for modifying an RDS Custom for SQL Server DB instance in general. For more information, see [Modifying an RDS Custom for SQL Server DB instance \(p. 872\)](#).

For general information about upgrading DB instances, see [Upgrading a DB instance engine version \(p. 360\)](#).

Troubleshooting DB issues for Amazon RDS Custom

The shared responsibility model of RDS Custom provides OS shell-level access and database administrator access. RDS Custom runs resources in your account, unlike Amazon RDS, which runs resources in a system account. With greater access comes greater responsibility. In the following sections, you can learn how to troubleshoot issues with Amazon RDS Custom DB instances.

Topics

- [Viewing RDS Custom events \(p. 889\)](#)
- [Subscribing to event notifications \(p. 889\)](#)
- [Troubleshooting custom engine version creation for RDS Custom for Oracle \(p. 890\)](#)
- [RDS Custom support perimeter and unsupported configurations \(p. 891\)](#)
- [Fixing unsupported configurations \(p. 891\)](#)
- [How Amazon RDS Custom replaces an impaired host \(p. 897\)](#)
- [Troubleshooting upgrades for RDS Custom for Oracle \(p. 899\)](#)
- [Troubleshooting replica promotion for RDS Custom for Oracle \(p. 900\)](#)
- [Troubleshooting replica creation for RDS Custom for Oracle \(p. 900\)](#)

Viewing RDS Custom events

The procedure for viewing events is the same for RDS Custom and Amazon RDS DB instances. For more information, see [Viewing Amazon RDS events \(p. 647\)](#).

To view RDS Custom event notification using the AWS CLI, use the `describe-events` command. RDS Custom introduces several new events. The event categories are the same as for Amazon RDS. For the list of events, see [Amazon RDS event categories and event messages \(p. 668\)](#).

The following example retrieves details for the events that have occurred for the specified RDS Custom DB instance.

```
aws rds describe-events \
    --source-identifier my-custom-instance \
    --source-type db-instance
```

Subscribing to event notifications

The procedure for subscribing to events is the same for RDS Custom and Amazon RDS DB instances. For more information, see [Subscribing to Amazon RDS event notification \(p. 655\)](#).

To subscribe to RDS Custom event notification using the CLI, use `create-event-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

The following example creates a subscription for backup and recovery events for an RDS Custom DB instance in the current AWS account. Notifications are sent to an Amazon Simple Notification Service (Amazon SNS) topic, specified by `--sns-topic-arn`.

```
aws rds create-event-subscription \
--subscription-name my-instance-events \
--source-type db-instance \

```

Troubleshooting custom engine version creation for RDS Custom for Oracle

When CEV creation fails, RDS Custom issues RDS-EVENT-0198 with the message **Creation failed for custom engine version *major-engine-version.cev_name***, and includes details about the failure. For example, the event prints missing files.

CEV creation might fail because of the following issues:

- The Amazon S3 bucket containing your installation files isn't in the same AWS Region as your CEV.
- When you request CEV creation in an AWS Region for the first time, RDS Custom creates an S3 bucket for storing RDS Custom resources (such as CEV artifacts, AWS CloudTrail logs, and transaction logs).

CEV creation fails if RDS Custom can't create the S3 bucket. Either the caller doesn't have S3 permissions as described in [Grant required permissions to your IAM user \(p. 778\)](#), or the number of S3 buckets has reached the limit.

- The caller doesn't have permissions to get files from your S3 bucket that contains the installation media files. These permissions are described in [Adding necessary IAM permissions \(p. 798\)](#).
- Your IAM policy has an `aws:SourceIp` condition. Make sure to follow the recommendations in [AWS Denies access to AWS based on the source IP](#) in the *AWS Identity and Access Management User Guide*. Also make sure that the caller has the S3 permissions described in [Grant required permissions to your IAM user \(p. 778\)](#).
- Installation media files listed in the CEV manifest aren't in your S3 bucket.
- The SHA-256 checksums of the installation files are unknown to RDS Custom.

Confirm that the SHA-256 checksums of the provided files match the SHA-256 checksum on the Oracle website. If the checksums match, contact [AWS Support](#) and provide the failed CEV name, file name, and checksum.

- The OPatch version is incompatible with your patch files. You might get the following message: `OPatch is lower than minimum required version.` Check that the version meets the requirements for all patches, and try again. To apply an Oracle patch, you must use a compatible version of the OPatch utility. You can find the required version of the Opatch utility in the readme file for the patch. Download the most recent OPatch utility from My Oracle Support, and try creating your CEV again.
- The patches specified in the CEV manifest are in the wrong order.

You can view RDS events either on the RDS console (in the navigation pane, choose **Events**) or by using the `describe-events` AWS CLI command. The default duration is 60 minutes. If no events are returned, specify a longer duration, as shown in the following example.

```
aws rds describe-events --duration 360
```

Currently, the MediaImport service that imports files from Amazon S3 to create CEVs isn't integrated with AWS CloudTrail. Therefore, if you turn on data logging for Amazon RDS in CloudTrail, calls to the MediaImport service such as the `CreateCustomDbEngineVersion` event aren't logged.

However, you might see calls from the API gateway that accesses your Amazon S3 bucket. These calls come from the MediaImport service for the `CreateCustomDbEngineVersion` event.

RDS Custom support perimeter and unsupported configurations

RDS Custom provides monitoring capability called the *support perimeter*. The support perimeter ensures that your RDS Custom instance uses a supported AWS infrastructure, operating system, and database.

The support perimeter checks that the requirements listed in [Fixing unsupported configurations \(p. 891\)](#) are met. If any of these requirements aren't met, RDS Custom considers the DB instance to be outside of the support perimeter. RDS Custom then changes the DB instance status to unsupported-configuration, and sends event notifications. After you fix the configuration problems, RDS Custom changes the DB instance status to available.

What happens in the unsupported-configuration state

While the DB instance is in the unsupported-configuration state, the following is the case:

- You can't modify the DB instance.
- You can't take DB snapshots.
- Automated backups aren't created.
- RDS Custom automation doesn't replace the underlying Amazon EC2 instance if it becomes impaired.

However, the following RDS Custom automation continues to run:

- The RDS Custom agent monitors the DB instance and sends notifications to the support perimeter of further changes.
- The support perimeter continues to run and captures change events for the DB instance. This has two purposes:
 - When you fix the configuration that caused the DB instance to be in the unsupported-configuration state, the support perimeter can return the DB instance to the available state.
 - If you make other unsupported configurations, the support perimeter notifies you about them so that you can correct them.
- Redo logs are still archived and uploaded to Amazon S3 to facilitate point-in-time recovery (PITR). However, be aware of the following:
 - PITR can take a long time to completely restore to a new DB instance. This is because you can't take either automated or manual snapshots while the DB instance is in the unsupported-configuration state.

PITR has to replay more redo logs starting from the most recent snapshot taken before the instance entered the unsupported-configuration state.

- In some cases, the DB instance is in the unsupported-configuration state because of changes you made that impacted redo log upload functionality. In these cases, PITR can't restore the DB instance to the latest restorable time.

Fixing unsupported configurations

It's your responsibility to fix configuration issues that put your RDS Custom DB instance into the unsupported-configuration state. If the issue is with the AWS infrastructure, you can use the console or the AWS CLI to fix it. If the issue is with the operating system or the database configuration, you can log in to the host to fix it.

In the following table, you can find descriptions of the notifications that the support perimeter sends and how to fix them. These notifications and the support perimeter are subject to change.

Notification	Description	Action
Database health:	<ul style="list-style-type: none"> You need to manually recover the database on EC2 instance [i-XXXXXXXXXXXXXXXXXX]. The DB instance restarted. 	<p>The support perimeter monitors the DB instance state. It also monitors how many restarts occurred during the previous hour and day.</p> <p>You're notified when the instance is in a state where it still exists, but you can't interact with it.</p> <p>Log in to the host and examine the database state.</p> <pre>ps -eo pid,state,command grep smon</pre> <p>Restart the DB instance if necessary to get it running again. Sometimes it's necessary to reboot the host.</p> <p>After the restart, the RDS Custom agent detects that the DB instance is no longer in an unresponsive state. It then notifies the support perimeter to reevaluate the DB instance state.</p>
Database archive lag target (RDS Custom for Oracle only):	<ul style="list-style-type: none"> The monitored Archive Lag Target database parameter on Amazon EC2 instance [i-XXXXXXXXXXXXXXXXXX] has changed from [300] to [0]. The RDS Custom instance is using an unsupported configuration because of the following [1] issue(s): (1) The archive lag target database parameter on Amazon EC2 instance [i-XXXXXXXXXXXXXXXXXX] is out of desired range {"lowerbound":60,"upperbound":7200}. 	<p>The support perimeter monitors the ARCHIVE_LAG_TARGET database parameter to verify that the DB instance's latest restorable time is within reasonable bounds.</p> <p>Log in to the host, connect to the DB instance, and change the ARCHIVE_LAG_TARGET parameter to a value from 60–7200.</p> <p>For example, use the following SQL command.</p> <pre>alter system set archive_lag_target=300 scope=both;</pre> <p>The DB instance becomes available within 30 minutes.</p>
Database log mode (RDS Custom for Oracle only):	<p>The monitored log mode of the database on Amazon EC2 instance [i-XXXXXXXXXXXXXXXXXX] has changed from [ARCHIVELOG] to [NOARCHIVELOG].</p>	<p>The DB instance log mode must be set to ARCHIVELOG.</p> <p>Log in to the host and shut down the DB instance. You can use the following SQL command.</p> <pre>shutdown immediate;</pre> <p>The RDS Custom agent restarts the DB instance and sets the log mode to ARCHIVELOG.</p> <p>The DB instance becomes available within 30 minutes.</p>
RDS Custom agent status (RDS Custom for Oracle):	<p>The monitored state of the RDS Custom agent on EC2 instance</p>	<p>The RDS Custom agent must always be running. The agent publishes the IamAlive metric to Amazon CloudWatch every 30 seconds. An alarm is</p> <p>Log in to the host and make sure that the RDS Custom agent is running.</p> <p>You can use the following commands to find the agent's status.</p>

Notification	Description	Action
<p>[i-XXXXXXXXXXXXXXXXXX] has changed from RUNNING to STOPPED.</p>	<p>triggered if the metric hasn't been published for 30 seconds.</p> <p>The support perimeter also monitors the RDS Custom agent process state on the host every 30 minutes.</p> <p>On RDS Custom for Oracle, the DB instance goes outside the support perimeter if the RDS Custom agent stops.</p>	<pre>ps -ef grep RDSCustomAgent</pre> <pre>pgrep java</pre> <p>When the RDS Custom agent is running again, the IamAlive metric is published to Amazon CloudWatch, and the alarm switches to the OK state. This switch notifies the support perimeter that the agent is running.</p>
<p>RDS Custom agent status (RDS Custom for SQL Server):</p> <p>The RDS Custom instance is going out of perimeter because an unsupported configuration was used for RDS Custom agent.</p>	<p>The RDS Custom agent must always be running.</p> <p>The support perimeter monitors the RDS Custom agent process state on the host every 1 minute.</p> <p>On RDS Custom for SQL Server, a stopped agent is recovered by the monitoring service. The DB instance goes outside the support perimeter if the RDS Custom agent is uninstalled.</p>	<p>Log in to the host and make sure that the RDS Custom agent is running.</p> <p>You can use the following commands to find the agent's status.</p> <pre>\$name = "RDSCustomAgent" \$service = Get-Service \$name Write-Host \$service.Status</pre> <p>If the status isn't Running, you can start the service with the following command:</p> <pre>Start-Service \$name</pre>
<p>AWS Systems Manager agent (SSM agent) status (RDS Custom for Oracle):</p> <p>The AWS Systems Manager agent on EC2 instance [i-XXXXXXXXXXXXXXXXXX] is currently unreachable. Make sure you have correctly configured the network, agent, and IAM permissions.</p>	<p>The SSM agent must always be running. The RDS Custom agent is responsible for making sure that the Systems Manager agent is running.</p> <p>If the SSM agent was down and restarted, the RDS Custom agent publishes a metric to CloudWatch. The RDS Custom agent has an alarm on the metric set to trigger when there has been a restart in each of the previous three minutes.</p> <p>The support perimeter also monitors the SSM agent process state on the host every 30 minutes.</p>	<p>For more information, see Troubleshooting SSM Agent.</p> <p>When the SSM agent is running again, the alarm switches to the OK state. This switch notifies the support perimeter that the agent is running.</p>

Notification	Description	Action
<p>SSM agent status (RDS Custom for SQL Server):</p> <p>The RDS Custom instance is going out of perimeter because an unsupported configuration was used for SSM agent.</p>	<p>The SSM agent must always be running. The RDS Custom agent is responsible for making sure that the Systems Manager agent is running.</p> <p>The support perimeter monitors the SSM agent process state on the host every 1 minute.</p>	<p>For more information, see Troubleshooting SSM Agent.</p>
<p>sudo configurations (RDS Custom for Oracle only):</p> <p>The sudo configurations on EC2 instance [i-xxxxxxxxxxxxxxxxxx] have changed.</p>	<p>The support perimeter monitors that certain OS users are allowed to run certain commands on the box. It monitors sudo configurations against the supported state.</p> <p>When the sudo configurations aren't supported, the RDS Custom tries to overwrite them back to the previous supported state. If that is successful, the following notification is sent:</p> <p>RDS Custom successfully overwrote your configuration.</p>	<p>If the overwrite is unsuccessful, you can log in to the host and investigate why recent changes to the sudo configurations aren't supported.</p> <p>You can use the following command.</p> <pre data-bbox="904 756 1480 825"><code>visudo -c -f /etc/sudoers.d/<i>individual_sudo_files</i></code></pre> <p>After the support perimeter determines that the sudo configurations are supported, the DB instance becomes available within 30 minutes.</p>

Notification	Description	Action
<p>Amazon Elastic Block Store (Amazon EBS) volumes:</p> <p>RDS Custom for Oracle:</p> <ul style="list-style-type: none"> The following Amazon EBS volumes are attached to Amazon EC2 instance [i-xxxxxxxxxxxxxxxxxxxx]: [[vol- <i>01234abcd56789ef0</i>, vol- <i>0def6789abcd01234</i>]]. The original Amazon EBS volumes attached to Amazon EC2 instance [i-xxxxxxxxxxxxxxxxxxxx] have been detached or modified. You can't attach or modify the initial EBS volumes attached to an RDS Custom instance. <p>RDS Custom for SQL Server:</p> <ul style="list-style-type: none"> The RDS Custom instance is going out of perimeter because an unsupported configuration was used for EBS volume metadata. 	<p>RDS Custom creates two types of EBS volume, besides the root volume created from the Amazon Machine Image (AMI), and associates them with the EC2 instance.</p> <p>The binary volume is where the database software binaries are located. The data volumes are where database files are located. The storage configurations that you set when creating the DB instance are used to configure the data volumes.</p> <p>The support perimeter monitors the following:</p> <ul style="list-style-type: none"> The initial EBS volumes created with the DB instance are still associated. The initial EBS volumes still have the same configurations as initially set: storage type, size, Provisioned IOPS, and storage throughput. (RDS Custom for Oracle only) No additional EBS volumes are attached to the DB instance. 	<p>If you detached any initial EBS volumes, contact AWS Support.</p> <p>If you modified the storage type, Provisioned IOPS, or storage throughput of an EBS volume, revert the modification to the original value.</p> <p>If you modified the storage size of an EBS volume, contact AWS Support.</p> <p>(RDS Custom for Oracle only) If you attached any additional EBS volumes, do either of the following:</p> <ul style="list-style-type: none"> Detach the additional EBS volumes from the RDS Custom DB instance. Contact AWS Support.
<p>EBS-optimized instances (RDS Custom for Oracle only):</p> <p>The EBS-optimized attribute of Amazon EC2 instance [i-xxxxxxxxxxxxxxxxxxxx] has changed from [enabled] to [disabled].</p>	<p>Amazon EC2 instances should be EBS optimized.</p> <p>If the EBS-optimized attribute is turned off (disabled), the support perimeter doesn't put the DB instance into the unsupported-configuration state.</p>	<p>To turn on the EBS-optimized attribute:</p> <ol style="list-style-type: none"> Stop the EC2 instance. Set the EBS-optimized attribute to enabled. Start the EC2 instance. Remount the binary and data volumes.

Notification	Description	Action
<p>Amazon EC2 instance state:</p> <ul style="list-style-type: none"> The state of the EC2 instance [<i>i-XXXXXXXXXXXXXXXXXX</i>] has changed from [RUNNING] to [STOPPING]. The Amazon EC2 instance [<i>i-XXXXXXXXXXXXXXXXXX</i>] has been terminated and can't be found. Delete the database instance to clean up resources. The Amazon EC2 instance [<i>i-XXXXXXXXXXXXXXXXXX</i>] has been stopped. Start the instance, and restore the host configuration. For more information, see the troubleshooting documentation. 	<p>The support perimeter monitors EC2 instance state-change notifications. The EC2 instance must always be running.</p>	<p>If the EC2 instance is stopped, start it and remount the binary and data volumes.</p> <p>On RDS Custom for Oracle, if the EC2 instance is terminated, delete the RDS Custom DB instance.</p> <p>On RDS Custom for SQL Server, if the EC2 instance is terminated, RDS Custom performs an automated recovery to provision a new EC2 instance.</p>
<p>Amazon EC2 instance attributes:</p> <p>RDS Custom for Oracle:</p> <ul style="list-style-type: none"> The attributes of Amazon EC2 instance [<i>i-XXXXXXXXXXXXXXXXXX</i>] have changed. <p>RDS Custom for SQL Server:</p> <ul style="list-style-type: none"> The RDS Custom instance is going out of perimeter because an unsupported configuration was used for EC2 instance metadata. 	<p>The support perimeter monitors the instance type of the EC2 instance where the RDS Custom DB instance is running. The EC2 instance type must stay the same as when you set it up during RDS Custom DB instance creation.</p>	<p>Change the EC2 instance type back to the original type using the EC2 console or CLI.</p> <p>To change the instance type because of scaling requirements, do a PITR and specify the new instance type and class. However, doing this results in a new RDS Custom DB instance with a new host and Domain Name System (DNS) name.</p>
<p>Oracle Data Guard role (RDS Custom for Oracle only):</p> <ul style="list-style-type: none"> The instance role for DB instance <i>my-custom-instance</i> was changed. The database role [LOGICAL STANDBY] isn't supported. Validate the Oracle Data Guard configuration for the database on Amazon EC2 instance [<i>i-XXXXXXXXXXXXXXXXXX</i>]. 	<p>The support perimeter monitors the current database role every 15 seconds and sends a CloudWatch notification if the database role has changed.</p> <p>The Oracle Data Guard DATABASE_ROLE parameter must be either PRIMARY or PHYSICAL STANDBY.</p>	<p>Restore the Oracle Data Guard database role to a supported value.</p> <p>After the support perimeter determines that the database role is supported, the RDS Custom for Oracle DB instance becomes available within 15 seconds.</p>

Notification	Description	Action
<p>Shared memory connections (RDS Custom for SQL Server only):</p> <p>The RDS Custom instance is going out of perimeter because an unsupported configuration was used for shared memory protocol.</p>	<p>The RDS Custom agent on the EC2 host connects to SQL Server using the shared memory protocol.</p> <p>If this protocol is turned off (Enabled is set to No), then RDS Custom can't perform its management actions and places the DB instance outside the support perimeter.</p>	<p>To bring the RDS Custom for SQL Server DB instance back within the support perimeter, turn on the shared memory protocol on the Protocol page of the Shared Memory Properties window by setting Enabled to Yes.</p> <p>Restart SQL Server after enabling the protocol.</p>
<p>Database file locations (RDS Custom for SQL Server only):</p> <p>The RDS Custom instance is going out of perimeter because an unsupported configuration was used for database files location.</p>	<p>All SQL Server database files are stored on the D: drive by default, in the D:\rdsdbdata\DATA directory.</p> <p>If you create or alter the database file location to be anywhere other than the D: drive, then RDS Custom places the DB instance outside the support perimeter.</p> <p>We strongly recommend that you don't save any database files on the C: drive. You can lose data on the C: drive during certain operations, such as hardware failure. Storage on the C: drive doesn't offer the same durability as on the D: drive, which is an EBS volume.</p> <p>Also, if database files can't be found, RDS Custom places the DB instance outside the support perimeter.</p>	<p>Store all RDS Custom for SQL Server database files on the D: drive.</p>

How Amazon RDS Custom replaces an impaired host

If the Amazon EC2 host becomes impaired, RDS Custom attempts to reboot it. If this effort fails, RDS Custom uses the same stop and start feature included in Amazon EC2.

Topics

- [Stopping and starting the host \(p. 898\)](#)
- [Effects of host replacement \(p. 898\)](#)
- [Best practices for Amazon EC2 hosts \(p. 898\)](#)

Stopping and starting the host

RDS Custom automatically takes the following steps, with no user intervention required:

1. Stops the Amazon EC2 host.

The EC2 instance performs a normal shutdown and stops running. Any Amazon EBS volumes remain attached to the instance, and their data persists. Any data stored in the instance store volumes (not supported on RDS Custom) or RAM of the host computer is gone.

For more information, see [Stop and start your instance](#) in the *Amazon EC2 User Guide for Linux Instances*.

2. Starts the Amazon EC2 host.

The EC2 instance migrates to a new underlying host hardware. In some cases, the RDS Custom DB instance remains on the original host.

Effects of host replacement

In RDS Custom, you have full control over the root device volume and Amazon EBS storage volumes. The root volume can contain important data and configurations that you don't want to lose.

RDS Custom for Oracle retains all database and customer data after the operation, including root volume data. No user intervention is required. On RDS Custom for SQL Server, database data is retained, but any data on the C: drive, including operating system and customer data, is lost.

After the replacement process, the Amazon EC2 host has a new public IP address. The host retains the following:

- Instance ID
- Private IP addresses
- Elastic IP addresses
- Instance metadata
- Data storage volume data
- Root volume data (on RDS Custom for Oracle)

Best practices for Amazon EC2 hosts

The Amazon EC2 host replacement feature covers the majority of Amazon EC2 impairment scenarios. We recommend that you adhere to the following best practices:

- Before you change your configuration or the operating system, back up your data. If the root volume or operating system becomes corrupt, host replacement can't repair it. Your only options are restoring from a DB snapshot or point-in-time recovery.
- Don't manually stop or terminate the physical Amazon EC2 host. Both actions result in the instance being put outside the RDS Custom support perimeter.
- (RDS Custom for SQL Server) If you attach additional volumes to the Amazon EC2 host, configure them to remount upon restart. If the host is impaired, RDS Custom might stop and start the host automatically.

Troubleshooting upgrades for RDS Custom for Oracle

Your upgrade of an RDS Custom for Oracle instance might fail. Following, you can find techniques that you can use during upgrades of RDS Custom DB for Oracle DB instances:

- Examine the following log files:
 - All upgrade output log files reside in the /tmp directory on the DB instance.
 - These log files are named catupg*.log.
 - A master output file named /tmp/catupgrd0.log reports all errors, and the steps performed.
 - The alert.log file for the DB instance is located in the /rdsdbdata/log/trace directory. Examine this file regularly as a best practice.
- Run the following grep command in the root directory to track the upgrade OS process. This command shows where the log files are being written and determine the state of the upgrade process.

```
ps -aux | grep upg
```

The output resembles the following.

```
root      18884  0.0  0.0 235428  8172 ?        S<   17:03   0:00 /usr/bin/sudo -u rdsdb /rdsdbbin/scripts/oracle-control ORCL op_apply_upgrade_sh RDS-UPGRADE/2.upgrade.sh
rdsdb    18886  0.0  0.0 153968 12164 ?        S<   17:03   0:00 /usr/bin/perl -T -w /rdsdbbin/scripts/oracle-control ORCL op_apply_upgrade_sh RDS-UPGRADE/2.upgrade.sh
rdsdb    18887  0.0  0.0 113196  3032 ?        S<   17:03   0:00 /bin/sh /rdsdbbin/oracle/rdbms/admin/RDS-UPGRADE/2.upgrade.sh
rdsdb    18900  0.0  0.0 113196  1812 ?        S<   17:03   0:00 /bin/sh /rdsdbbin/oracle/rdbms/admin/RDS-UPGRADE/2.upgrade.sh
rdsdb    18901  0.1  0.0 167652  20620 ?        S<   17:03   0:07 /rdsdbbin/oracle/perl/bin/perl catctl.pl -n 4 -d /rdsdbbin/oracle/rdbms/admin -l /tmp catupgrd.sql
root      29944  0.0  0.0 112724  2316 pts/0    S+   18:43   0:00 grep --color=auto upg
```

- Run the following SQL query to verify the current state of the components to find the database version and the options installed on the DB instance.

```
set linesize 180
column comp_id format a15
column comp_name format a40 trunc
column status format a15 trunc
select comp_id, comp_name, version, status from dba_registry order by 1;
```

The output resembles the following.

COMP_NAME	STATUS	PROCEDURE
-----	-----	-----
Oracle Database Catalog Views	VALID	
DBMS_REGISTRY_SYS.VALIDATE_CATALOG		
Oracle Database Packages and Types	VALID	
DBMS_REGISTRY_SYS.VALIDATE_CATPROC		
Oracle Text	VALID	VALID_CONTEXT
Oracle XML Database	VALID	DBMS_REGXDB.VALIDATEXDB
4 rows selected.		

- Run the following SQL query to check for invalid objects that might interfere with the upgrade process.

```
set pages 1000 lines 2000
```

```
col OBJECT for a40
Select substr(owner,1,12) owner,
       substr(object_name,1,30) object,
       substr(object_type,1,30) type, status,
       created
  from
    dba_objects where status <>'VALID' and owner in ('SYS','SYSTEM','RDSADMIN','XDB');
```

Troubleshooting replica promotion for RDS Custom for Oracle

You can promote managed Oracle replicas in RDS Custom for Oracle using the console, `promote-read-replica` AWS CLI command, or `PromoteReadReplica` API. If you delete your primary DB instance, and all replicas are healthy, RDS Custom for Oracle promotes your managed replicas to standalone instances automatically. If a replica has paused automation or is outside the support perimeter, you must fix the replica before RDS Custom can promote it automatically. For more information, see [Replica promotion requirements and limitations \(p. 829\)](#).

The replica promotion workflow might become stuck in the following situation:

- The primary DB instance is in the state `STORAGE_FULL`.
- The primary DB can't archive all of its online redo logs.
- A gap exists between the archived redo log files on your Oracle replica and the primary database.

To respond to the stuck workflow, complete the following steps:

1. Synchronize the redo log gap on your Oracle replica DB instance.
2. Force the promotion of your read replica to the latest applied redo log. Run the following commands in SQL*Plus:

```
ALTER DATABASE ACTIVATE STANDBY DATABASE;
SHUTDOWN IMMEDIATE
STARTUP
```

3. Contact AWS Support and request it to move your DB instance to available status.

Troubleshooting replica creation for RDS Custom for Oracle

When you attempt to create a new Oracle replica from an RDS Custom for Oracle DB instance that was created before November 18, 2022, the replication becomes stuck. You can fix this problem by creating a new SPFILE on the Oracle replica that is experiencing the problem.

To create a new SPFILE on your Oracle replica

1. Log in to the underlying Amazon EC2 instance for your Oracle replica. Use `sed` to change the current Oracle home value of `/rdsdbbin/oracle` to the latest Oracle home in your initialization parameter file.

```
sed -i "s|/rdsdbbin/oracle|${ORACLE_HOME}|g" /rdsdbdata/config/oracle_pfile
```

2. Start an Oracle SQL client, and log in to your RDS Custom for Oracle DB instance as a user with SYSDBA privileges.
3. In your SQL client, create an SPFILE from your initialization parameter file.

```
CREATE SPFILE='/rdsdbdata/admin/$ORACLE_SID/pfile/spfile$ORACLE_SID.ora'  
FROM PFILE='/rdsdbdata/config/oracle_pfile';
```

4. Shut down your Oracle replica database:

```
SHUTDOWN IMMEDIATE
```

5. Start your Oracle replica database and mount it:

```
STARTUP MOUNT
```

Your source RDS Custom for Oracle DB instance can now replicate to your Oracle replica database.

Working with Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts extends RDS for SQL Server, RDS for MySQL, and RDS for PostgreSQL databases to AWS Outposts environments. AWS Outposts uses the same hardware as in public AWS Regions to bring AWS services, infrastructure, and operation models on-premises. With RDS on Outposts, you can provision managed DB instances close to the business applications that must run on-premises. For more information about AWS Outposts, see [AWS Outposts](#).

You use the same AWS Management Console, AWS CLI, and RDS API to provision and manage on-premises RDS on Outposts DB instances as you do for RDS DB instances running in the AWS Cloud. RDS on Outposts automates tasks, such as database provisioning, operating system and database patching, backup, and long-term archival in Amazon S3.

RDS on Outposts supports automated backups of DB instances. Network connectivity between your Outpost and your AWS Region is required to back up and restore DB instances. All DB snapshots and transaction logs from an Outpost are stored in your AWS Region. From your AWS Region, you can restore a DB instance from a DB snapshot to a different Outpost. For more information, see [Working with backups \(p. 427\)](#).

RDS on Outposts supports automated maintenance and upgrades of DB instances. For more information, see [Maintaining a DB instance \(p. 350\)](#).

RDS on Outposts uses encryption at rest for DB instances and DB snapshots using your AWS KMS key. For more information about encryption at rest, see [Encrypting Amazon RDS resources \(p. 2000\)](#).

By default, EC2 instances in Outposts subnets can use the Amazon Route 53 DNS Service to resolve domain names to IP addresses. You might encounter longer DNS resolution times with Route 53, depending on the path latency between your Outpost and the AWS Region. In such cases, you can use the DNS servers installed locally in your on-premises environment. For more information, see [DNS](#) in the [AWS Outposts User Guide](#).

When network connectivity to the AWS Region isn't available, your DB instance continues to run locally. You can continue to access DB instances using DNS name resolution by configuring a local DNS server as a secondary server. However, you can't create new DB instances or take new actions on existing DB instances. Automatic backups don't occur when there is no connectivity. If there is a DB instance failure, the DB instance isn't automatically replaced until connectivity is restored. We recommend restoring network connectivity as soon as possible.

Topics

Prerequisites for Amazon RDS on AWS Outposts

The following are prerequisites for using Amazon RDS on AWS Outposts:

- Install AWS Outposts in your on-premises data center. For more information about AWS Outposts, see [AWS Outposts](#).
- Make sure that you have at least one subnet available for RDS on Outposts. You can use the same subnet for other workloads.
- Make sure that you have a reliable network connection between your Outpost and an AWS Region.

Amazon RDS on AWS Outposts support for Amazon RDS features

The following table describes the Amazon RDS features supported by Amazon RDS on AWS Outposts.

Feature	Supported	Notes	More information
DB instance provisioning	Yes	You can only create DB instances for RDS for SQL Server, RDS for MySQL, and RDS for PostgreSQL DB engines. The following versions are supported: <ul style="list-style-type: none"> Microsoft SQL Server: <ul style="list-style-type: none"> 15.00.4043.16.v1 and higher 2019 versions 14.00.3294.2.v1 and higher 2017 versions 13.00.5820.21.v1 and higher 2016 versions MySQL version 8.0.23 and higher MySQL 8.0 versions All PostgreSQL 14 & 13 versions, and PostgreSQL version 12.5 and higher PostgreSQL 12 versions 	Creating DB instances for Amazon RDS on AWS Outposts (p. 914)
Connect to a Microsoft SQL Server DB instance with Microsoft SQL Server Management Studio	Yes	Some TLS versions and encryption ciphers might not be secure. To turn them off, follow the instructions in Configuring security protocols and ciphers (p. 1138) .	Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1084)
Modifying the master user password	Yes	—	Modifying an Amazon RDS DB instance (p. 327)
Renaming a DB instance	Yes	—	Modifying an Amazon RDS DB instance (p. 327)
Rebooting a DB instance	Yes	—	Rebooting a DB instance (p. 366)
Stopping a DB instance	Yes	—	Stopping an Amazon RDS DB instance temporarily (p. 317)
Starting a DB instance	Yes	—	Starting an Amazon RDS DB instance that was previously stopped (p. 320)

Feature	Supported	Notes	More information
Multi-AZ deployments	Yes	Multi-AZ deployments are supported on MySQL and PostgreSQL DB instances.	Creating DB instances for Amazon RDS on AWS Outposts (p. 914) Multi-AZ deployments for high availability (p. 121)
DB parameter groups	Yes	—	Working with parameter groups (p. 289)
Read replicas	No	—	Working with read replicas (p. 370)
Encryption at rest	Yes	RDS on Outposts doesn't support unencrypted DB instances.	Encrypting Amazon RDS resources (p. 2000)
AWS Identity and Access Management (IAM) database authentication	No	—	IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2048)
Associating an IAM role with a DB instance	No	—	add-role-to-db-instance AWS CLI command AddRoleToDBInstance RDS API operation
Kerberos authentication	No	—	Kerberos authentication (p. 1999)
Tagging Amazon RDS resources	Yes	—	Tagging Amazon RDS resources (p. 392)
Option groups	Yes	—	Working with option groups (p. 273)
Modifying the maintenance window	Yes	—	Maintaining a DB instance (p. 350)
Automatic minor version upgrade	Yes	—	Automatically upgrading the minor engine version (p. 362)
Modifying the backup window	Yes	—	Working with backups (p. 427) Modifying an Amazon RDS DB instance (p. 327)
Changing the DB instance class	Yes	—	Modifying an Amazon RDS DB instance (p. 327)
Changing the allocated storage	Yes	—	Modifying an Amazon RDS DB instance (p. 327)

Feature	Supported	Notes	More information
Storage autoscaling	Yes	—	Managing capacity automatically with Amazon RDS storage autoscaling (p. 412)
Manual and automatic DB instance snapshots	Yes	<p>You can store automated backups and manual snapshots in your AWS Region. Or you can store them locally on your Outpost.</p> <p>Local backups are supported on MySQL and PostgreSQL DB instances.</p> <p>To store backups on your Outpost, make sure that you have Amazon S3 on Outposts configured.</p>	Creating DB instances for Amazon RDS on AWS Outposts (p. 914) Amazon S3 on Outposts Creating a DB snapshot (p. 448)
Restoring from a DB snapshot	Yes	You can store automated backups and manual snapshots for the restored DB instance in the parent AWS Region or locally on your Outpost.	Considerations for restoring DB instances on Amazon RDS on AWS Outposts (p. 920) Restoring from a DB snapshot (p. 452)
Restoring a DB instance from Amazon S3	No	—	Restoring a backup into a MySQL DB instance (p. 1361)
Exporting snapshot data to Amazon S3	No	—	Exporting DB snapshot data to Amazon S3 (p. 481)
Point-in-time recovery	Yes	You can store automated backups and manual snapshots for the restored DB instance in the parent AWS Region or locally on your Outpost, with one exception.	Considerations for restoring DB instances on Amazon RDS on AWS Outposts (p. 920) Restoring a DB instance to a specified time (p. 499)
Enhanced monitoring	No	—	Monitoring OS metrics with Enhanced Monitoring (p. 600)
Amazon CloudWatch monitoring	Yes	You can view the same set of metrics that are available for your databases in the AWS Region.	Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 528)
Publishing database engine logs to CloudWatch Logs	Yes	—	Publishing database logs to Amazon CloudWatch Logs (p. 683)

Feature	Supported	Notes	More information
Event notification	Yes	—	Working with Amazon RDS event notification (p. 650)
Amazon RDS Performance Insights	No	—	Monitoring DB load with Performance Insights on Amazon RDS (p. 543)
Viewing or downloading database logs	No	<p>RDS on Outposts doesn't support viewing database logs using the console or describing database logs using the AWS CLI or RDS API.</p> <p>RDS on Outposts doesn't support downloading database logs using the console or downloading database logs using the AWS CLI or RDS API.</p>	Monitoring Amazon RDS log files (p. 680)
Amazon RDS Proxy	No	—	Using Amazon RDS Proxy (p. 921)
Stored procedures for Amazon RDS for MySQL	Yes	—	MySQL on Amazon RDS SQL reference (p. 1439)
Replication with external databases for RDS for MySQL	No	—	Configuring binary log file position replication with an external source instance (p. 1408)
Native backup and restore for Amazon RDS for Microsoft SQL Server	Yes	—	Importing and exporting SQL Server databases using native backup and restore (p. 1099)

Supported DB instance classes for Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts supports the following DB instance classes:

- General purpose DB instance classes
 - db.m5.24xlarge
 - db.m5.12xlarge
 - db.m5.4xlarge
 - db.m5.2xlarge
 - db.m5.xlarge
 - db.m5.large
- Memory optimized DB instance classes

- db.r5.24xlarge
- db.r5.12xlarge
- db.r5.4xlarge
- db.r5.2xlarge
- db.r5.xlarge
- db.r5.large

Depending on how you've configured your Outpost, you might not have all of these classes available. For example, if you haven't purchased the db.r5 classes for your Outpost, you can't use them with RDS on Outposts.

Only general purpose SSD storage is supported for RDS on Outposts DB instances. For more information about DB instance classes, see [DB instance classes \(p. 10\)](#).

Amazon RDS manages maintenance and recovery for your DB instances and requires active capacity on the Outpost to do so. We recommend that you configure N+1 EC2 instances for each DB instance class in your production environments. RDS on Outposts can use the extra capacity of these EC2 instances for maintenance and repair operations. For example, if your production environments have 3 db.m5.large and 5 db.r5.xlarge DB instance classes, then we recommend that they have at least 4 m5.large EC2 instances and 6 r5.xlarge EC2 instances. For more information, see [Resilience in AWS Outposts](#) in the [AWS Outposts User Guide](#).

Customer-owned IP addresses for Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts uses information that you provide about your on-premises network to create an address pool. This pool is known as a *customer-owned IP address pool* (CoIP pool). *Customer-owned IP addresses* (CoIPs) provide local or external connectivity to resources in your Outpost subnets through your on-premises network. For more information about CoIPs, see [Customer-owned IP addresses](#) in the *AWS Outposts User Guide*.

Each RDS on Outposts DB instance has a private IP address for traffic inside its virtual private cloud (VPC). This private IP address isn't publicly accessible. You can use the **Public** option to set whether the DB instance also has a public IP address in addition to the private IP address. Using the public IP address for connections routes them through the internet and can result in high latencies in some cases.

Instead of using these private and public IP addresses, RDS on Outposts supports using CoIPs for DB instances through their subnets. When you use a CoIP for an RDS on Outposts DB instance, you connect to the DB instance with the DB instance endpoint. RDS on Outposts then automatically uses the CoIP for all connections from both inside and outside of the VPC.

CoIPs can provide the following benefits for RDS on Outposts DB instances:

- Lower connection latency
- Enhanced security

Using CoIPs

You can turn CoIPs on or off for an RDS on Outposts DB instance using the AWS Management Console, the AWS CLI, or the RDS API:

- With the AWS Management Console, choose the **Customer-owned IP address (CoIP)** setting in **Access type** to use CoIPs. Choose one of the other settings to turn them off.

▼ Additional configuration

Access type [Info](#)

Private

RDS will not assign a public IP address to the database. Amazon EC2 instances and devices inside the VPC can connect to your database. EC2 instances and devices outside your VPC can't connect unless they use AWS Site-to-Site VPN or AWS Direct Connect.

Customer-owned IP address (CoIP)

Devices on your on-premises network can connect to your database through a CoIP.

Public

Amazon EC2 instances and devices outside the VPC can connect to your database. Choose one or more VPC security groups that specify which EC2 instances and devices can connect to the database.

Database port

TCP/IP port that the database will use for application connections.

3306

- With the AWS CLI, use the `--enable-customer-owned-ip` | `--no-enable-customer-owned-ip` option.
- With the RDS API, use the `EnableCustomerOwnedIp` parameter.

You can turn CoIPs on or off when you perform any of the following actions:

- Create a DB instance

For more information, see [Creating DB instances for Amazon RDS on AWS Outposts \(p. 914\)](#).

- Modify a DB instance

For more information, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

- Restore a DB instance from a snapshot

For more information, see [Restoring from a DB snapshot \(p. 452\)](#).

- Restore a DB instance to a specified time

For more information, see [Restoring a DB instance to a specified time \(p. 499\)](#).

Note

In some cases, you might turn on CoIPs for a DB instance but Amazon RDS isn't able to allocate a CoIP for the DB instance. In such cases, the DB instance status is changed to **incompatible-network**. For more information about the DB instance status, see [Viewing Amazon RDS DB instance status \(p. 516\)](#).

Limitations

The following limitations apply to CoIP support for RDS on Outposts DB instances:

- When using a CoIP for a DB instance, make sure that public accessibility is turned off for that DB instance.
- Make sure that the inbound rules for your VPC security groups include the CoIP address range (CIDR block). For more information about setting up security groups, see [Provide access to your DB instance in your VPC by creating a security group \(p. 151\)](#).
- You can't assign a CoIP from a CoIP pool to a DB instance. When you use a CoIP for a DB instance, Amazon RDS automatically assigns a CoIP from a CoIP pool to the DB instance.
- You must use the AWS account that owns the Outpost resources (owner) or share the following resources with other AWS accounts (consumers) in the same organization:
 - The Outpost
 - The local gateway (LGW) route table for the DB instance's VPC
 - The CoIP pool or pools for the LGW route table

For more information, see [Working with shared AWS Outposts resources](#) in the *AWS Outposts User Guide*.

Working with Multi-AZ deployments for Amazon RDS on AWS Outposts

For Multi-AZ deployments, Amazon RDS creates a primary DB instance on one AWS Outpost. RDS synchronously replicates the data to a standby DB instance on a different Outpost.

Multi-AZ deployments on AWS Outposts operate like Multi-AZ deployments in AWS Regions, but with the following differences:

- They require a local connection between two or more Outposts.
- They require customer-owned IP (CoIP) pools. For more information, see [Customer-owned IP addresses for Amazon RDS on AWS Outposts \(p. 909\)](#).
- Replication runs on your local network.

Multi-AZ on AWS Outposts is available for all supported versions of MySQL and PostgreSQL on RDS on Outposts. Local backups aren't supported for Multi-AZ deployments. For more information, see [Creating DB instances for Amazon RDS on AWS Outposts \(p. 914\)](#).

Working with the shared responsibility model

Although AWS uses commercially reasonable efforts to provide DB instances configured for high availability, the availability uses a shared responsibility model. The ability of RDS on Outposts to fail over and repair DB instances requires each of your Outposts to be connected to its AWS Region.

RDS on Outposts also requires connectivity between the Outpost that is hosting the primary DB instance and the Outpost that is hosting the standby DB instance for synchronous replication. Any impact to this connection can prevent RDS on Outposts from performing a failover.

You might see elevated latencies for a standard DB instance deployment as a result of the synchronous data replication. The bandwidth and latency of the connection between the Outpost hosting the primary DB instance and the Outpost hosting the standby DB instance directly affect latencies. For more information, see [Prerequisites \(p. 912\)](#).

Improving availability

We recommend the following actions to improve availability:

- Allocate enough additional capacity for your mission-critical applications to allow recovery and failover if there is an underlying host issue. This applies to all Outposts that contain subnets in your DB subnet group. For more information, see [Resilience in AWS Outposts](#).
- Create multiple connections from each of your Outposts to the AWS Region.
- Use more than two Outposts. Having more than two Outposts allows Amazon RDS to recover a DB instance. RDS does this recovery by moving the DB instance to another Outpost if the current Outpost experiences a failure.
- Provide dual power sources and redundant network connectivity for your Outpost.

We recommend the following for your local networks:

- The round trip time (RTT) latency between the Outpost hosting your primary DB instance and the Outpost hosting your standby DB instance directly affects write latency. Keep the RTT latency between the AWS Outposts in the low single-digit milliseconds. We recommend not more than 5 milliseconds, but your requirements might vary.

You can find the net impact to network latency in the Amazon CloudWatch metrics for `WriteLatency`. For more information, see [Amazon CloudWatch metrics for Amazon RDS \(p. 609\)](#).

- The availability of the connection between the Outposts affects the overall availability of your DB instances. Have redundant network connectivity between the Outposts.

Prerequisites

Multi-AZ deployments on RDS on Outposts have the following prerequisites:

- Have at least two Outposts, connected over local connections and attached to different Availability Zones in an AWS Region.
- Make sure that your DB subnet groups contain the following:
 - At least two subnets in at least two Availability Zones in a given AWS Region.
 - Subnets only in Outposts.
 - At least two subnets in at least two Outposts within the same virtual private cloud (VPC).
- Associate your DB instance's VPC with all of your local gateway route tables. This association is necessary because replication runs over your local network using your Outposts' local gateways.

For example, suppose that your VPC contains subnet-A in Outpost-A and subnet-B in Outpost-B. Outpost-A uses LocalGateway-A (LGW-A), and Outpost-B uses LocalGateway-B (LGW-B). LGW-A has RouteTable-A, and LGW-B has RouteTable-B. You want to use both RouteTable-A and RouteTable-B for replication traffic. To do this, associate your VPC with both RouteTable-A and RouteTable-B.

For more information about how to create an association, see the Amazon EC2 [create-local-gateway-route-table-vpc-association](#) AWS CLI command.

- Make sure that your Outposts use customer-owned IP (CoIP) routing. Each route table must also each have at least one address pool. Amazon RDS allocates an additional IP address each for the primary and standby DB instances for data synchronization.
- Make sure that the AWS account that owns the RDS DB instances owns the local gateway route tables and CoIP pools. Or make sure it's part of a Resource Access Manager share with access to the local gateway route tables and CoIP pools.
- Make sure that the IP addresses in your CoIP pools can be routed from one Outpost local gateway to the others.
- Make sure that the VPC's CIDR blocks (for example, 10.0.0.0/4) and your CoIP pool CIDR blocks don't contain IP addresses from Class E (240.0.0.0/4). RDS uses these IP addresses internally.
- Make sure that you correctly set up outbound and related inbound traffic.

RDS on Outposts establishes a virtual private network (VPN) connection between the primary and standby DB instances. For this to work correctly, your local network must allow outbound and related inbound traffic for Internet Security Association and Key Management Protocol (ISAKMP). It does so using User Datagram Protocol (UDP) port 500 and IP Security (IPsec) Network Address Translation Traversal (NAT-T) using UDP port 4500.

For more information on CoIPs, see [Customer-owned IP addresses for Amazon RDS on AWS Outposts \(p. 909\)](#) in this guide, and [Customer-owned IP addresses](#) in the [AWS Outposts User Guide](#).

Working with API operations for Amazon EC2 permissions

Regardless of whether you use CoIPs for your DB instance on AWS Outposts, RDS requires access to your CoIP pool resources. RDS can call the following EC2 permissions API operations for CoIPs on your behalf for Multi-AZ deployments:

- `CreateCoipPoolPermission` – When you create a Multi-AZ DB instance on RDS on Outposts
- `DeleteCoipPoolPermission` – When you delete a Multi-AZ DB instance on RDS on Outposts

These API operations grant to, or remove from, internal RDS accounts the permission to allocate elastic IP addresses from the CoIP pool specified by the permission. You can view these IP addresses using the `DescribeCoipPoolUsage` API operation. For more information on CoIPs, see [Customer-owned IP addresses for Amazon RDS on AWS Outposts \(p. 909\)](#) and [Customer-owned IP addresses in the AWS Outposts User Guide](#).

RDS can also call the following EC2 permission API operations for local gateway route tables on your behalf for Multi-AZ deployments:

- `CreateLocalGatewayRouteTablePermission` – When you create a Multi-AZ DB instance on RDS on Outposts
- `DeleteLocalGatewayRouteTablePermission` – When you delete a Multi-AZ DB instance on RDS on Outposts

These API operations grant to, or remove from, internal RDS accounts the permission to associate internal RDS VPCs with your local gateway route tables. You can view these route table–VPC associations using the `DescribeLocalGatewayRouteTableVpcAssociations` API operations.

Creating DB instances for Amazon RDS on AWS Outposts

Creating an Amazon RDS on AWS Outposts DB instance is similar to creating an Amazon RDS DB instance in the AWS Cloud. However, make sure that you specify a DB subnet group that is associated with your Outpost.

A virtual private cloud (VPC) based on the Amazon VPC service can span all of the Availability Zones in an AWS Region. You can extend any VPC in the AWS Region to your Outpost by adding an Outpost subnet. To add an Outpost subnet to a VPC, specify the Amazon Resource Name (ARN) of the Outpost when you create the subnet.

Before you create an RDS on Outposts DB instance, you can create a DB subnet group that includes one subnet that is associated with your Outpost. When you create an RDS on Outposts DB instance, specify this DB subnet group. You can also choose to create a new DB subnet group when you create your DB instance.

For information about configuring AWS Outposts, see the [AWS Outposts User Guide](#).

Console

Creating a DB subnet group

Create a DB subnet group with one subnet that is associated with your Outpost.

You can also create a new DB subnet group for the Outpost when you create your DB instance. If you want to do so, then skip this procedure.

Note

To create a DB subnet group for the AWS Cloud, specify at least two subnets.

To create a DB subnet group for your Outpost

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB subnet group.
3. Choose **Subnet groups**, and then choose **Create DB Subnet Group**.

The **Create DB subnet group** page appears.

Create DB Subnet Group

To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.

Subnet group details

Name

You won't be able to modify the name after your subnet group has been created.

Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

Description

(Optional)

VPC

Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won't be able to choose a different VPC identifier after your subnet group has been created.

Choose a VPC

Add subnets

Availability Zones

Choose the Availability Zones that include the subnets you want to add.

Choose an availability zone

Subnets

Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.

Select subnets

4. For **Name**, choose the name of the DB subnet group.
5. For **Description**, choose a description for the DB subnet group.
6. For **VPC**, choose the VPC that you're creating the DB subnet group for.
7. For **Availability Zones**, choose the Availability Zone for your Outpost.
8. For **Subnets**, choose the subnet for use by RDS on Outposts.
9. Choose **Create** to create the DB subnet group.

Creating the RDS on Outposts DB instance

Create the DB instance, and choose the Outpost for your DB instance.

To create an RDS on Outposts DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where the Outpost on which you want to create the DB instance is attached.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.

The AWS Management Console detects available Outposts that you have configured and presents the **On-premises** option in the **Database location** section.

Note

If you haven't configured any Outposts, either the **Database location** section doesn't appear or the **RDS on Outposts** option isn't available in the **Choose an on-premises creation method** section.

5. For **Database location**, choose **On-premises**.
6. For **On-premises creation method**, choose **RDS on Outposts**.
7. Specify your settings for **Outposts Connectivity**. These settings are for the Outpost that uses the VPC that has the DB subnet group for your DB instance. Your VPC must be based on the Amazon VPC service.
 - a. For **Virtual Private Cloud (VPC)**, choose the VPC that contains the DB subnet group for your DB instance.
 - b. For **VPC security group**, choose the Amazon VPC security group for your DB instance.
 - c. For **DB subnet group**, choose the DB subnet group for your DB instance.

You can choose an existing DB subnet group that's associated with the Outpost—for example, if you performed the procedure in [Creating a DB subnet group \(p. 914\)](#).

You can also create a new DB subnet group for the Outpost.

8. For **Multi-AZ deployment**, choose **Create a standby instance (recommended for production usage)** to create a standby DB instance in another Outpost.

Note

This option isn't available for Microsoft SQL Server.

If you choose to create a Multi-AZ deployment, you can't store backups on your Outpost.

9. Under **Backup**, do the following:

- a. For **Backup target**, choose one of the following:
 - **AWS Cloud** to store automated backups and manual snapshots in the parent AWS Region.
 - **Outposts (on-premises)** to create local backups.

Note

To store backups on your Outpost, your Outpost must have Amazon S3 capability.

For more information, see [Amazon S3 on Outposts](#).

Local backups aren't supported for Multi-AZ deployments.

- b. Choose **Enable automated backups** to create point-in-time snapshots of your DB instance.

If you turn on automated backups, then you can choose values for **Backup retention period** and **Backup window**, or leave the default values.

10. Specify other DB instance settings as needed.

For information about each setting when creating a DB instance, see [Settings for DB instances \(p. 237\)](#).

11. Choose **Create database**.

The **Databases** page appears. A banner tells you that your DB instance is being created, and displays the **View credential details** button.

Viewing DB instance details

After you create your DB instance, you can view credentials and other details for it.

To view DB instance details

1. To view the master user name and password for the DB instance, choose **View credential details** on the **Databases** page.

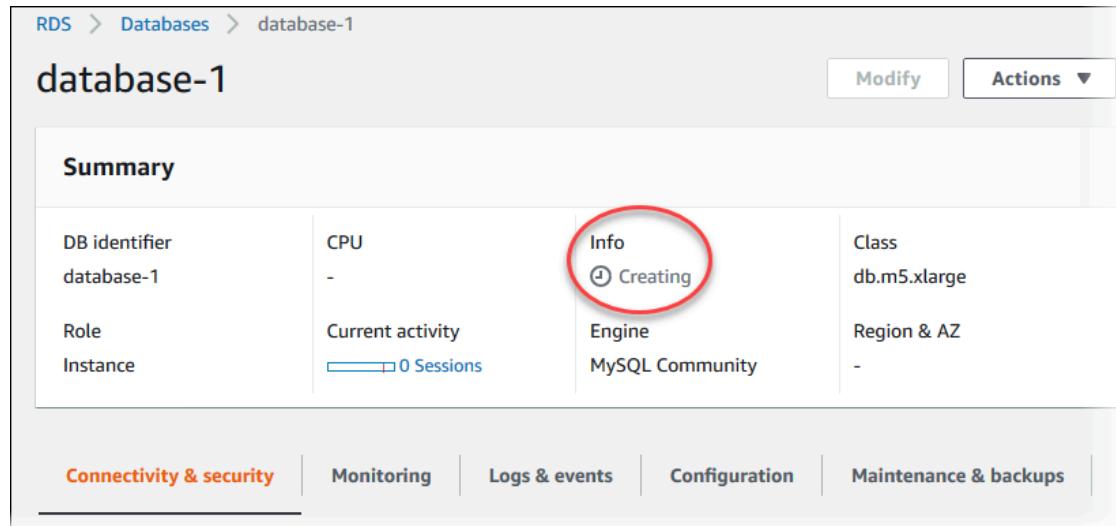

You can connect to the DB instance as the master user by using these credentials.

Important

You can't view the master user password again. If you don't record it, you might have to change it. To change the master user password after the DB instance is available, modify the DB instance. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

2. Choose the name of the new DB instance on the **Databases** page.

On the RDS console, the details for the new DB instance appear. The DB instance has a status of **Creating** until the DB instance is created and ready for use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and storage allocated, it can take several minutes for the new DB instance to be available.

After the DB instance is available, you can manage it the same way that you manage RDS DB instances in the AWS Cloud.

AWS CLI

Before you create a new DB instance in an Outpost with the AWS CLI, first create a DB subnet group for use by RDS on Outposts.

To create a DB subnet group for your Outpost

- Use the [create-db-subnet-group](#) command. For `--subnet-ids`, specify the subnet group in the Outpost for use by RDS on Outposts.

For Linux, macOS, or Unix:

```
aws rds create-db-subnet-group \
--db-subnet-group-name myoutpostdbsubnetgr \
--db-subnet-group-description "DB subnet group for RDS on Outposts" \
--subnet-ids subnet-abc123
```

For Windows:

```
aws rds create-db-subnet-group ^
--db-subnet-group-name myoutpostdbsubnetgr ^
--db-subnet-group-description "DB subnet group for RDS on Outposts" ^
--subnet-ids subnet-abc123
```

To create an RDS on Outposts DB instance using the AWS CLI

- Use the [create-db-instance](#) command. Specify an Availability Zone for the Outpost, an Amazon VPC security group associated with the Outpost, and the DB subnet group you created for the Outpost. You can include the following options:

- `--db-instance-identifier`
- `--db-instance-class`
- `--engine` – The database engine. Use one of the following values:
 - MySQL – Specify `mysql`.
 - PostgreSQL – Specify `postgres`.
 - Microsoft SQL Server – Specify `sqlserver-ee`, `sqlserver-se`, or `sqlserver-web`.
- `--availability-zone`
- `--vpc-security-group-ids`
- `--db-subnet-group-name`
- `--allocated-storage`
- `--max-allocated-storage`
- `--master-username`
- `--master-user-password`
- `--multi-az` | `--no-multi-az` – (Optional) Whether to create a standby DB instance in a different Availability Zone. The default is `--no-multi-az`.

The `--multi-az` option isn't available for SQL Server.

- `--backup-retention-period`
- `--backup-target` – (Optional) Where to store automated backups and manual snapshots. Use one of the following values:
 - `outposts` – Store them locally on your Outpost.
 - `region` – Store them in the parent AWS Region. This is the default value.

If you use the `--multi-az` option, you can't use `outposts` for `--backup-target`.

- `--storage-encrypted`
- `--kms-key-id`

Example

The following example creates a MySQL DB instance named `myoutpostdbinstance` with backups stored on your Outpost.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier myoutpostdbinstance \
--engine-version 8.0.17 \
--db-instance-class db.m5.large \
--engine mysql \
--availability-zone us-east-1d \
--vpc-security-group-ids outpost-sg \
--db-subnet-group-name myoutpostdbsubnetgr \
--allocated-storage 100 \
--max-allocated-storage 1000 \
--master-username masterawsuser \
--master-user-password masteruserpassword \
--backup-retention-period 3 \
--backup-target outposts \
--storage-encrypted \
--kms-key-id mykey
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier myoutpostdbinstance ^
--engine-version 8.0.17 ^
--db-instance-class db.m5.large ^
--engine mysql ^
--availability-zone us-east-1d ^
--vpc-security-group-ids outpost-sg ^
--db-subnet-group-name myoutpostdbsubnetgr ^
--allocated-storage 100 ^
--max-allocated-storage 1000 ^
--master-username masterawsuser ^
--master-user-password masteruserpassword ^
--backup-retention-period 3 ^
--backup-target outposts ^
--storage-encrypted ^
--kms-key-id mykey
```

For information about each setting when creating a DB instance, see [Settings for DB instances \(p. 237\)](#).

RDS API

To create a new DB instance in an Outpost with the RDS API, first create a DB subnet group for use by RDS on Outposts by calling the [CreateDBSubnetGroup](#) operation. For SubnetIds, specify the subnet group in the Outpost for use by RDS on Outposts.

Next, call the [CreateDBInstance](#) operation with the following parameters. Specify an Availability Zone for the Outpost, an Amazon VPC security group associated with the Outpost, and the DB subnet group you created for the Outpost.

- `AllocatedStorage`
- `AvailabilityZone`
- `BackupRetentionPeriod`
- `BackupTarget`

- `DBInstanceClass`
- `DBInstanceIdentifier`
- `VpcSecurityGroupIds`
- `DBSubnetGroupName`
- `Engine`
- `EngineVersion`
- `MasterUsername`
- `MasterUserPassword`
- `MaxAllocatedStorage` (optional)
- `MultiAZ` (optional)
- `StorageEncrypted`
- `KmsKeyID`

For information about each setting when creating a DB instance, see [Settings for DB instances \(p. 237\)](#).

Considerations for restoring DB instances on Amazon RDS on AWS Outposts

When you restore a DB instance in Amazon RDS on AWS Outposts, you can generally choose the storage location for automated backups and manual snapshots of the restored DB instance.

- When restoring from a manual DB snapshot, you can store backups either in the parent AWS Region or locally on your Outpost.
- When restoring from an automated backup (point-in-time recovery), you have fewer choices:
 - If restoring from the parent AWS Region, you can store backups either in the AWS Region or on your Outpost.
 - If restoring from your Outpost, you can store backups only on your Outpost.

Using Amazon RDS Proxy

By using Amazon RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. By using RDS Proxy, you can also enforce AWS Identity and Access Management (IAM) authentication for databases, and securely store credentials in AWS Secrets Manager.

Using RDS Proxy, you can handle unpredictable surges in database traffic. Otherwise, these surges might cause issues due to oversubscribing connections or creating new connections at a fast rate. RDS Proxy establishes a database connection pool and reuses connections in this pool. This approach avoids the memory and CPU overhead of opening a new database connection each time. To protect the database against oversubscription, you can control the number of database connections that are created.

RDS Proxy queues or throttles application connections that can't be served immediately from the pool of connections. Although latencies might increase, your application can continue to scale without abruptly failing or overwhelming the database. If connection requests exceed the limits you specify, RDS Proxy rejects application connections (that is, it sheds load). At the same time, it maintains predictable performance for the load that can be served with the available capacity.

You can reduce the overhead to process credentials and establish a secure connection for each new connection. RDS Proxy can handle some of that work on behalf of the database.

RDS Proxy is fully compatible with the engine versions that it supports. You can enable RDS Proxy for most applications with no code changes.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with RDS Proxy, see [Amazon RDS Proxy \(p. 114\)](#).

Quotas and limitations for RDS Proxy

The following quotas and limitations apply to RDS Proxy:

- You can have up to 20 proxies for each AWS account ID. If your application requires more proxies, you can request additional proxies by opening a ticket with the AWS Support organization.
- Each proxy can have up to 200 associated Secrets Manager secrets. Thus, each proxy can connect to up to 200 different user accounts at any given time.
- You can create, view, modify, and delete up to 20 endpoints for each proxy. These endpoints are in addition to the default endpoint that's automatically created for each proxy.
- In an Aurora cluster, all of the connections using the default proxy endpoint are handled by the Aurora writer instance. To perform load balancing for read-intensive workloads, you can create a read-only endpoint for a proxy. That endpoint passes connections to the reader endpoint of the cluster. That way, your proxy connections can take advantage of Aurora read scalability. For more information, see [Overview of proxy endpoints \(p. 953\)](#).

For RDS DB instances in replication configurations, you can associate a proxy only with the writer DB instance, not a read replica.

- You can use RDS Proxy with Aurora Serverless v2 clusters but not with Aurora Serverless v1 clusters.
- Using RDS Proxy with Aurora clusters that are part of an Aurora global database isn't currently supported.
- Your RDS Proxy must be in the same virtual private cloud (VPC) as the database. The proxy can't be publicly accessible, although the database can be. For example, if you're prototyping on a local host, you can't connect to your RDS Proxy unless you set up dedicated networking. This is the case because your local host is outside of the proxy's VPC.

Note

For Aurora DB clusters, you can turn on cross-VPC access. To do this, create an additional endpoint for a proxy and specify a different VPC, subnets, and security groups with that endpoint. For more information, see [Accessing Aurora and RDS databases across VPCs \(p. 954\)](#).

- You can't use RDS Proxy with a VPC that has its tenancy set to dedicated.
- If you use RDS Proxy with an RDS DB instance or Aurora DB cluster that has IAM authentication enabled, check user authentication. Make sure that all users who connect through a proxy authenticate through user names and passwords. For details about IAM support in RDS Proxy, see [Setting up AWS Identity and Access Management \(IAM\) policies \(p. 932\)](#).
- You can't use RDS Proxy with custom DNS.
- Each proxy can be associated with a single target DB instance or cluster. However, you can associate multiple proxies with the same DB instance or cluster.
- Any statement with a text size greater than 16 KB causes the proxy to pin the session to the current connection.

For additional limitations for each DB engine, see the following sections:

- [Additional limitations for RDS for MariaDB \(p. 922\)](#)
- [Additional limitations for RDS for Microsoft SQL Server \(p. 923\)](#)
- [Additional limitations for RDS for MySQL \(p. 923\)](#)
- [Additional limitations for RDS for PostgreSQL \(p. 924\)](#)

Additional limitations for RDS for MariaDB

The following additional limitations apply to RDS Proxy with RDS for MariaDB databases:

- Currently, all proxies listen on port 3306 for MariaDB. The proxies still connect to your database using the port that you specified in the database settings.

- You can't use RDS Proxy with self-managed MariaDB databases in Amazon EC2 instances.
- You can't use RDS Proxy with an RDS for MariaDB DB instance that has the `read_only` parameter in its DB parameter group set to 1.
- RDS Proxy doesn't support compressed mode. For example, it doesn't support the compression used by the `--compress` or `-C` options of the `mysql` command.
- Some SQL statements and functions can change the connection state without causing pinning. For the most current pinning behavior, see [Avoiding pinning \(p. 948\)](#).
- RDS Proxy doesn't support the MariaDB `auth_ed25519` plugin.
- RDS Proxy doesn't support Transport Layer Security (TLS) version 1.3 for MariaDB databases.

Important

For proxies associated with MariaDB databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

Additional limitations for RDS for Microsoft SQL Server

The following additional limitations apply to RDS Proxy with RDS for Microsoft SQL Server databases:

- The number of Secrets Manager secrets that you need to create for a proxy depends on the collation that your DB instance uses. For example, suppose that your DB instance uses case-sensitive collation. If your application accepts both "Admin" and "admin," then your proxy needs two separate secrets. For more information about collation in SQL Server, see the [Microsoft SQL Server](#) documentation.
- RDS Proxy doesn't support connections that use Active Directory.
- You can't use IAM authentication with clients that don't support token properties. For more information, see [Considerations for connecting to a proxy with Microsoft SQL Server \(p. 940\)](#).
- The results of `@@IDENTITY`, `@@ROWCOUNT`, and `SCOPE_IDENTITY` aren't always accurate. As a work-around, retrieve their values in the same session statement to ensure that they return the correct information.
- If the connection uses multiple active result sets (MARS), RDS Proxy doesn't run the initialization queries. For information about MARS, see the [Microsoft SQL Server](#) documentation.

Additional limitations for RDS for MySQL

The following additional limitations apply to RDS Proxy with RDS for MySQL databases:

- RDS Proxy doesn't support the MySQL `sha256_password` and `caching_sha2_password` authentication plugins. These plugins implement SHA-256 hashing for user account passwords.
- Currently, all proxies listen on port 3306 for MySQL. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MySQL databases in EC2 instances.
- You can't use RDS Proxy with an RDS for MySQL DB instance that has the `read_only` parameter in its DB parameter group set to 1.
- RDS Proxy doesn't support MySQL compressed mode. For example, it doesn't support the compression used by the `--compress` or `-C` options of the `mysql` command.
- Some SQL statements and functions can change the connection state without causing pinning. For the most current pinning behavior, see [Avoiding pinning \(p. 948\)](#).

Important

For proxies associated with MySQL databases, don't set the configuration parameter `sql_auto_is_null` to true or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

Additional limitations for RDS for PostgreSQL

The following additional limitations apply to RDS Proxy with RDS for PostgreSQL databases:

- RDS Proxy doesn't support session pinning filters for PostgreSQL.
- RDS Proxy doesn't support PostgreSQL SCRAM-SHA-256 authentication.
- Currently, all proxies listen on port 5432 for PostgreSQL.
- For PostgreSQL, RDS Proxy doesn't currently support canceling a query from a client by issuing a `CancelRequest`. This is the case, for example, when you cancel a long-running query in an interactive `psql` session by using `Ctrl+C`.
- The results of the PostgreSQL function `lastval` aren't always accurate. As a work-around, use the `INSERT` statement with the `RETURNING` clause.
- RDS Proxy doesn't multiplex connections when your client application drivers use the PostgreSQL extended query protocol.
- RDS Proxy currently doesn't support streaming replication mode.

Planning where to use RDS Proxy

You can determine which of your DB instances, clusters, and applications might benefit the most from using RDS Proxy. To do so, consider these factors:

- Any DB instance or cluster that encounters "too many connections" errors is a good candidate for associating with a proxy. The proxy enables applications to open many client connections, while the proxy manages a smaller number of long-lived connections to the DB instance or cluster.
- For DB instances or clusters that use smaller AWS instance classes, such as T2 or T3, using a proxy can help avoid out-of-memory conditions. It can also help reduce the CPU overhead for establishing connections. These conditions can occur when dealing with large numbers of connections.
- You can monitor certain Amazon CloudWatch metrics to determine whether a DB instance or cluster is approaching certain types of limit. These limits are for the number of connections and the memory associated with connection management. You can also monitor certain CloudWatch metrics to determine whether a DB instance or cluster is handling many short-lived connections. Opening and closing such connections can impose performance overhead on your database. For information about the metrics to monitor, see [Monitoring RDS Proxy metrics with Amazon CloudWatch \(p. 959\)](#).
- AWS Lambda functions can also be good candidates for using a proxy. These functions make frequent short database connections that benefit from connection pooling offered by RDS Proxy. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
- Applications that typically open and close large numbers of database connections and don't have built-in connection pooling mechanisms are good candidates for using a proxy.
- Applications that keep a large number of connections open for long periods are typically good candidates for using a proxy. Applications in industries such as software as a service (SaaS) or ecommerce often minimize the latency for database requests by leaving connections open. With RDS Proxy, an application can keep more connections open than it can when connecting directly to the DB instance or cluster.
- You might not have adopted IAM authentication and Secrets Manager due to the complexity of setting up such authentication for all DB instances and clusters. If so, you can leave the existing authentication methods in place and delegate the authentication to a proxy. The proxy can enforce

the authentication policies for client connections for particular applications. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.

- RDS Proxy can help make applications more resilient and transparent to database failures. RDS Proxy bypasses Domain Name System (DNS) caches to reduce failover times by up to 66% for Amazon RDS Multi-AZ databases. RDS Proxy also automatically routes traffic to a new database instance while preserving application connections. This makes failovers more transparent for applications.

RDS Proxy concepts and terminology

You can simplify connection management for your Amazon RDS DB instances and Amazon Aurora DB clusters by using RDS Proxy.

RDS Proxy handles the network traffic between the client application and the database. It does so in an active way first by understanding the database protocol. It then adjusts its behavior based on the SQL operations from your application and the result sets from the database.

RDS Proxy reduces the memory and CPU overhead for connection management on your database. The database needs less memory and CPU resources when applications open many simultaneous connections. It also doesn't require logic in your applications to close and reopen connections that stay idle for a long time. Similarly, it requires less application logic to reestablish connections in case of a database problem.

The infrastructure for RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). The computation, memory, and storage for RDS Proxy are independent of your RDS DB instances and Aurora DB clusters. This separation helps lower overhead on your database servers, so that they can devote their resources to serving database workloads. The RDS Proxy compute resources are serverless, automatically scaling based on your database workload.

- [Transactions \(p. 928\)](#)

Overview of RDS Proxy concepts

RDS Proxy handles the infrastructure to perform connection pooling and the other features described in the sections that follow. You see the proxies represented in the RDS console on the [Proxies](#) page.

Each proxy handles connections to a single RDS DB instance or Aurora DB cluster. The proxy automatically determines the current writer instance for RDS Multi-AZ DB instances and Aurora provisioned clusters. For Aurora multi-master clusters, the proxy connects to one of the writer instances and uses the other writer instances as hot standby targets.

The connections that a proxy keeps open and available for your database application to use make up the *connection pool*.

By default, RDS Proxy can reuse a connection after each transaction in your session. This transaction-level reuse is called *multiplexing*. When RDS Proxy temporarily removes a connection from the connection pool to reuse it, that operation is called *borrowing* the connection. When it's safe to do so, RDS Proxy returns that connection to the connection pool.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called *pinning*.

A proxy has a default endpoint. You connect to this endpoint when you work with an RDS DB instance or Aurora DB cluster. You do so instead of connecting to the read/write endpoint that connects directly to the instance or cluster. The special-purpose endpoints for an Aurora cluster remain available for you to use. For Aurora DB clusters, you can also create additional read/write and read-only endpoints. For more information, see [Overview of proxy endpoints \(p. 953\)](#).

For example, you can still connect to the cluster endpoint for read/write connections without connection pooling. You can still connect to the reader endpoint for load-balanced read-only connections. You can still connect to the instance endpoints for diagnosis and troubleshooting of specific DB instances within an Aurora cluster. If you use other AWS services such as AWS Lambda to connect to RDS databases, change their connection settings to use the proxy endpoint. For example, you specify the proxy endpoint to allow Lambda functions to access your database while taking advantage of RDS Proxy functionality.

Each proxy contains a target group. This *target group* embodies the RDS DB instance or Aurora DB cluster that the proxy can connect to. For an Aurora cluster, by default the target group is associated with all the DB instances in that cluster. That way, the proxy can connect to whichever Aurora DB instance is promoted to be the writer instance in the cluster. The RDS DB instance associated with a proxy, or the Aurora DB cluster and its instances, are called the *targets* of that proxy. For convenience, when you create a proxy through the console, RDS Proxy also creates the corresponding target group and registers the associated targets automatically.

An *engine family* is a related set of database engines that use the same DB protocol. You choose the engine family for each proxy that you create.

Connection pooling

Each proxy performs connection pooling for the writer instance of its associated RDS or Aurora database. *Connection pooling* is an optimization that reduces the overhead associated with opening and closing connections and with keeping many connections open simultaneously. This overhead includes memory needed to handle each new connection. It also involves CPU overhead to close each connection and open a new one. Examples include Transport Layer Security/Secure Sockets Layer (TLS/SSL) handshaking, authentication, negotiating capabilities, and so on. Connection pooling simplifies your application logic. You don't need to write application code to minimize the number of simultaneous open connections.

Each proxy also performs connection multiplexing, also known as connection reuse. With *multiplexing*, RDS Proxy performs all the operations for a transaction using one underlying database connection. RDS then can use a different connection for the next transaction. You can open many simultaneous connections to the proxy, and the proxy keeps a smaller number of connections open to the DB instance or cluster. Doing so further minimizes the memory overhead for connections on the database server. This technique also reduces the chance of "too many connections" errors.

RDS Proxy security

RDS Proxy uses the existing RDS security mechanisms such as TLS/SSL and AWS Identity and Access Management (IAM). For general information about those security features, see [Security in Amazon RDS \(p. 1997\)](#). Also, make sure to familiarize yourself with how RDS and Aurora work with authentication, authorization, and other areas of security.

RDS Proxy can act as an additional layer of security between client applications and the underlying database. For example, you can connect to the proxy using TLS 1.2, even if the underlying DB instance supports only TLS 1.0 or 1.1. You can connect to the proxy using an IAM role. This is so even if the proxy connects to the database using the native user and password authentication method. By using this technique, you can enforce strong authentication requirements for database applications without a costly migration effort for the DB instances themselves.

You store the database credentials used by RDS Proxy in AWS Secrets Manager. Each database user for the RDS DB instance or Aurora DB cluster accessed by a proxy must have a corresponding secret in Secrets Manager. You can also set up IAM authentication for users of RDS Proxy. By doing so, you can enforce IAM authentication for database access even if the databases use native password authentication. We recommend using these security features instead of embedding database credentials in your application code.

Using TLS/SSL with RDS Proxy

You can connect to RDS Proxy using the TLS/SSL protocol.

Note

RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you use RDS Proxy, when you rotate your TLS/SSL certificate you don't need to update applications that use RDS Proxy connections.

To enforce TLS for all connections between the proxy and your database, you can specify a setting **Require Transport Layer Security** when you create or modify a proxy.

RDS Proxy can also ensure that your session uses TLS/SSL between your client and the RDS Proxy endpoint. To have RDS Proxy do so, specify the requirement on the client side. SSL session variables are not set for SSL connections to a database using RDS Proxy.

- For RDS for MySQL and Aurora MySQL, specify the requirement on the client side with the `--ssl-` mode parameter when you run the `mysql` command.
- For Amazon RDS PostgreSQL and Aurora PostgreSQL, specify `sslmode=require` as part of the `conninfo` string when you run the `psql` command.

RDS Proxy supports TLS protocol version 1.0, 1.1, and 1.2. You can connect to the proxy using a higher version of TLS than you use in the underlying database.

By default, client programs establish an encrypted connection with RDS Proxy, with further control available through the `--ssl-mode` option. From the client side, RDS Proxy supports all SSL modes.

For the client, the SSL modes are the following:

PREFERRED

SSL is the first choice, but it isn't required.

DISABLED

No SSL is allowed.

REQUIRED

Enforce SSL.

VERIFY_CA

Enforce SSL and verify the certificate authority (CA).

VERIFY_IDENTITY

Enforce SSL and verify the CA and CA hostname.

When using a client with `--ssl-mode VERIFY_CA` or `VERIFY_IDENTITY`, specify the `--ssl-ca` option pointing to a CA in .pem format. For the .pem file to use, download all root CA PEMs from [Amazon Trust Services](#) and place them into a single .pem file.

RDS Proxy uses wildcard certificates, which apply to both a domain and its subdomains. If you use the `mysql` client to connect with SSL mode `VERIFY_IDENTITY`, currently you must use the MySQL 8.0-compatible `mysql` command.

Failover

Failover is a high-availability feature that replaces a database instance with another one when the original instance becomes unavailable. A failover might happen because of a problem with a database instance. It might also be part of normal maintenance procedures, such as during a database upgrade. Failover applies to RDS DB instances in a Multi-AZ configuration. Failover applies to Aurora DB clusters with one or more reader instances in addition to the writer instance.

Connecting through a proxy makes your application more resilient to database failovers. When the original DB instance becomes unavailable, RDS Proxy connects to the standby database without dropping idle application connections. Doing so helps to speed up and simplify the failover process. The result is faster failover that's less disruptive to your application than a typical reboot or database problem.

Without RDS Proxy, a failover involves a brief outage. During the outage, you can't perform write operations on that database. Any existing database connections are disrupted, and your application must reopen them. The database becomes available for new connections and write operations when a read-only DB instance is promoted in place of one that's unavailable.

During DB failovers, RDS Proxy continues to accept connections at the same IP address and automatically directs connections to the new primary DB instance. Clients connecting through RDS Proxy are not susceptible to the following:

- Domain Name System (DNS) propagation delays on failover.
- Local DNS caching.
- Connection timeouts.
- Uncertainty about which DB instance is the current writer.
- Waiting for a query response from a former writer that became unavailable without closing connections.

For applications that maintain their own connection pool, going through RDS Proxy means that most connections stay alive during failovers or other disruptions. Only connections that are in the middle of a transaction or SQL statement are canceled. RDS Proxy immediately accepts new connections. When the database writer is unavailable, RDS Proxy queues up incoming requests.

For applications that don't maintain their own connection pools, RDS Proxy offers faster connection rates and more open connections. It offloads the expensive overhead of frequent reconnects from the database. It does so by reusing database connections maintained in the RDS Proxy connection pool. This approach is particularly important for TLS connections, where setup costs are significant.

Transactions

All the statements within a single transaction always use the same underlying database connection. The connection becomes available for use by a different session when the transaction ends. Using the transaction as the unit of granularity has the following consequences:

- Connection reuse can happen after each individual statement when the RDS for MySQL or Aurora MySQL `autocommit` setting is turned on.
- Conversely, when the `autocommit` setting is turned off, the first statement you issue in a session begins a new transaction. For example, suppose that you enter a sequence of `SELECT`, `INSERT`, `UPDATE`, and other data manipulation language (DML) statements. In this case, connection reuse doesn't happen until you issue a `COMMIT`, `ROLLBACK`, or otherwise end the transaction.
- Entering a data definition language (DDL) statement causes the transaction to end after that statement completes.

RDS Proxy detects when a transaction ends through the network protocol used by the database client application. Transaction detection doesn't rely on keywords such as COMMIT or ROLLBACK appearing in the text of the SQL statement.

In some cases, RDS Proxy might detect a database request that makes it impractical to move your session to a different connection. In these cases, it turns off multiplexing for that connection the remainder of your session. The same rule applies if RDS Proxy can't be certain that multiplexing is practical for the session. This operation is called *pinning*. For ways to detect and minimize pinning, see [Avoiding pinning \(p. 948\)](#).

Getting started with RDS Proxy

In the following sections, you can find how to set up RDS Proxy. You can also find how to set related security options. These control who can access each proxy and how each proxy connects to DB instances.

Topics

- [Setting up network prerequisites \(p. 929\)](#)
- [Setting up database credentials in AWS Secrets Manager \(p. 931\)](#)
- [Setting up AWS Identity and Access Management \(IAM\) policies \(p. 932\)](#)
- [Creating an RDS Proxy \(p. 934\)](#)
- [Viewing an RDS Proxy \(p. 938\)](#)
- [Connecting to a database through RDS Proxy \(p. 939\)](#)

Setting up network prerequisites

Using RDS Proxy requires you to have a common virtual private cloud (VPC) between your Aurora DB cluster or RDS DB instance and RDS Proxy. This VPC should have a minimum of two subnets that are in different Availability Zones. Your account can either own these subnets or share them with other accounts. For information about VPC sharing, see [Work with shared VPCs](#). Your client application resources such as Amazon EC2, Lambda, or Amazon ECS can be in the same VPC as the proxy. Or they can be in a separate VPC from the proxy. If you successfully connected to any RDS DB instances or Aurora DB clusters, you already have the required network resources.

Topics

- [Getting information about your subnets \(p. 929\)](#)
- [Planning for IP address capacity \(p. 930\)](#)

Getting information about your subnets

The following Linux example shows AWS CLI commands that examine the VPCs and subnets owned by your AWS account. In particular, you pass subnet IDs as parameters when you create a proxy using the CLI.

```
aws ec2 describe-vpcs
aws ec2 describe-internet-gateways
aws ec2 describe-subnets --query '*[].[VpcId,SubnetId]' --output text | sort
```

The following Linux example shows AWS CLI commands to determine the subnet IDs corresponding to a specific Aurora DB cluster or RDS DB instance. For an Aurora cluster, first you find the ID for one of the associated DB instances. You can extract the subnet IDs used by that DB instance. To do so, examine the nested fields within the DBSubnetGroup and Subnets attributes in the describe output for the DB instance. You specify some or all of those subnet IDs when setting up a proxy for that database server.

```
$ # Optional first step, only needed if you're starting from an Aurora cluster. Find the ID
of any DB instance in the cluster.
$ aws rds describe-db-clusters --db-cluster-identifier my_cluster_id --query '*[]'.
[DBClusterMembers][0][0][*].DBInstanceIdentifier' --output text
my_instance_id
instance_id_2
instance_id_3
...
$ # From the DB instance, trace through the DBSubnetGroup and Subnets to find the subnet
IDs.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[]'.
[DBSubnetGroup][0][0][Subnets][0][*].SubnetIdentifier' --output text
subnet_id_1
subnet_id_2
subnet_id_3
...
```

Or you can first find the VPC ID for the DB instance. Then you can examine the VPC to find its subnets. The following Linux example shows how.

```
$ # From the DB instance, find the VPC.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[]'.
[DBSubnetGroup][0][0].VpcId' --output text
my_vpc_id

$ aws ec2 describe-subnets --filters Name=vpc-id,Values=my_vpc_id --query '*[].[SubnetId]'
--output text
subnet_id_1
subnet_id_2
subnet_id_3
subnet_id_4
subnet_id_5
subnet_id_6
```

Planning for IP address capacity

An RDS Proxy automatically adjusts its capacity as needed based on the size and number of DB instances registered with it. Certain operations might also require additional proxy capacity. Some examples are increasing the size of a registered database or internal RDS Proxy maintenance operations. During these operations, your proxy might need more IP addresses to provision the extra capacity. These additional addresses allow your proxy to scale without affecting your workload. A lack of free IP addresses in your subnets prevents a proxy from scaling up. This can lead to higher query latencies or client connection failures. RDS notifies you through event RDS-EVENT-0243 when there aren't enough free IP addresses in your subnets. For information about this event, see [Working with RDS Proxy events \(p. 964\)](#).

Following are the recommended minimum number of IP addresses to leave free in your subnets for your proxy based on DB instance class sizes.

DB instance class	Minimum free IP addresses
db.*.xlarge or smaller	10
db.*.2xlarge	15
db.*.4xlarge	25
db.*.8xlarge	45

DB instance class	Minimum free IP addresses
db.*.12xlarge	60
db.*.16xlarge	75
db.*.24xlarge	110

These numbers of recommended IP addresses are estimates for a proxy with only the default endpoint. A proxy with additional endpoints or read replicas might need more free IP addresses. For each additional endpoint, we recommend that you reserve three more IP addresses. For each read replica, we recommend that you reserve additional IP addresses as specified in the table based on that read replica's size.

Note

RDS Proxy never uses more than 215 IP addresses in a VPC.

Setting up database credentials in AWS Secrets Manager

For each proxy that you create, you first use the Secrets Manager service to store sets of user name and password credentials. You create a separate Secrets Manager secret for each database user account that the proxy connects to on the RDS DB instance or Aurora DB cluster.

In Secrets Manager, you create these secrets with values for the **username** and **password** fields. Doing so allows the proxy to connect to the corresponding database users on RDS DB instances or Aurora DB clusters that you associate with the proxy. To do this, you can use the setting **Credentials for other database**, **Credentials for RDS database**, or **Other type of secrets**. Fill in the appropriate values for the **User name** and **Password** fields, and placeholder values for any other required fields. The proxy ignores other fields such as **Host** and **Port** if they're present in the secret. Those details are automatically supplied by the proxy.

You can also choose **Other type of secrets**. In this case, you create the secret with keys named **username** and **password**.

Because the secrets used by your proxy aren't tied to a specific database server, you can reuse a secret across multiple proxies. To do so, use the same credentials across multiple database servers. For example, you might use the same credentials across a group of development and test servers.

To connect through the proxy as a specific user, make sure that the password associated with a secret matches the database password for that user. If there's a mismatch, you can update the associated secret in Secrets Manager. In this case, you can still connect to other accounts where the secret credentials and the database passwords do match.

Note

For RDS for SQL Server, the number of Secrets Manager secrets that you need to create for a proxy depends on the collation that your DB instance uses. For example, suppose that your DB instance uses case-sensitive collation. If your application accepts both "Admin" and "admin," then your proxy needs two separate secrets. For more information about collation in SQL Server, see the [Microsoft SQL Server](#) documentation.

When you create a proxy through the AWS CLI or RDS API, you specify the Amazon Resource Names (ARNs) of the corresponding secrets. You do so for all the DB user accounts that the proxy can access. In the AWS Management Console, you choose the secrets by their descriptive names.

For instructions about creating secrets in Secrets Manager, see the [Creating a secret](#) page in the Secrets Manager documentation. Use one of the following techniques:

- Use [Secrets Manager](#) in the console.
- To use the CLI to create a Secrets Manager secret for use with RDS Proxy, use a command such as the following.

```
aws secretsmanager create-secret \
--name "secret_name"
--description "secret_description"
--region region_name
--secret-string '{"username":"db_user","password":"db_user_password"}'
```

For example, the following commands create Secrets Manager secrets for two database users, one named admin and the other named app-user.

```
aws secretsmanager create-secret \
--name admin_secret_name --description "db admin user" \
--secret-string '{"username":"admin","password":"choose_your_own_password"}'

aws secretsmanager create-secret \
--name proxy_secret_name --description "application user" \
--secret-string '{"username":"app-user","password":"choose_your_own_password"}'
```

To see the secrets owned by your AWS account, use a command such as the following.

```
aws secretsmanager list-secrets
```

When you create a proxy using the CLI, you pass the Amazon Resource Names (ARNs) of one or more secrets to the --auth parameter. The following Linux example shows how to prepare a report with only the name and ARN of each secret owned by your AWS account. This example uses the --output table parameter that is available in AWS CLI version 2. If you are using AWS CLI version 1, use --output text instead.

```
aws secretsmanager list-secrets --query '*[].[Name,ARN]' --output table
```

To verify that you stored the correct credentials and in the right format in a secret, use a command such as the following. Substitute the short name or the ARN of the secret for [your_secret_name](#).

```
aws secretsmanager get-secret-value --secret-id your_secret_name
```

The output should include a line displaying a JSON-encoded value like the following.

```
"SecretString": "{\"username\":\"your_username\",\"password\":\"your_password\"}",
```

Setting up AWS Identity and Access Management (IAM) policies

After you create the secrets in Secrets Manager, you create an IAM policy that can access those secrets. For general information about using IAM with RDS and Aurora, see [Identity and access management for Amazon RDS \(p. 2016\)](#).

Tip

The following procedure applies if you use the IAM console. If you use the AWS Management Console for RDS, RDS can create the IAM policy for you automatically. In that case, you can skip the following procedure.

To create an IAM policy that accesses your Secrets Manager secrets for use with your proxy

1. Sign in to the IAM console. Follow the [Create role](#) process, as described in [Creating IAM roles](#). Include the **Add Role to Database** step.
2. For the new role, perform the **Add inline policy** step. Use the same general procedures as in [Editing IAM policies](#). Paste the following JSON into the JSON text box. Substitute your own account ID. Substitute your AWS Region for us-east-2. Substitute the Amazon Resource Names (ARNs) for the secrets that you created. For the kms :Decrypt action, substitute the ARN of the default AWS KMS key or your own KMS key. Which one you use depends on which one you used to encrypt the Secrets Manager secrets.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "secretsmanager:GetSecretValue",
            "Resource": [
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_1",
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_2"
            ]
        },
        {
            "Sid": "VisualEditor1",
            "Effect": "Allow",
            "Action": "kms:Decrypt",
            "Resource": "arn:aws:kms:us-east-2:account_id:key/key_id",
            "Condition": {
                "StringEquals": {
                    "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"
                }
            }
        }
    ]
}
```

3. Edit the trust policy for this IAM role. Paste the following JSON into the JSON text box.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

The following commands perform the same operation through the AWS CLI.

```
PREFIX=choose_an_identifier
aws iam create-role --role-name choose_role_name \
--assume-role-policy-document '{"Version":"2012-10-17","Statement": [{"Effect":"Allow","Principal":{"Service": ["rds.amazonaws.com"]}}, {"Action": "sts:AssumeRole"}]}'
```

```

aws iam put-role-policy --role-name same_role_name_as_previous \
--policy-name $PREFIX-secret-reader-policy --policy-document """
same_json_as_in_previous_example
"""

aws kms create-key --description "$PREFIX-test-key" --policy """
{
  "Id": "$PREFIX-kms-policy",
  "Version": "2012-10-17",
  "Statement":
  [
    {
      "Sid": "Enable IAM User Permissions",
      "Effect": "Allow",
      "Principal": {"AWS": "arn:aws:iam::account_id:root"},
      "Action": "kms:*",
      "Resource": "*"
    },
    {
      "Sid": "Allow access for Key Administrators",
      "Effect": "Allow",
      "Principal":
      {
        "AWS":
          ["$USER_ARN", "arn:aws:iam::account_id:role/Admin"]
      },
      "Action":
      [
        "kms:Create*",
        "kms:Describe*",
        "kms:Enable*",
        "kms>List*",
        "kms:Put*",
        "kms:Update*",
        "kms:Revoke*",
        "kms:Disable*",
        "kms:Get*",
        "kms>Delete*",
        "kms:TagResource",
        "kms:UntagResource",
        "kms:ScheduleKeyDeletion",
        "kms:CancelKeyDeletion"
      ],
      "Resource": "*"
    },
    {
      "Sid": "Allow use of the key",
      "Effect": "Allow",
      "Principal": {"AWS": "$ROLE_ARN"},

      "Resource": "*"
    }
  ]
}
"""

```

Creating an RDS Proxy

To manage connections for a specified set of DB instances, you can create a proxy. You can associate a proxy with an RDS for MariaDB, RDS for Microsoft SQL Server, RDS for MySQL, or RDS for PostgreSQL DB instance.

AWS Management Console

To create a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Choose **Create proxy**.
4. Choose all the settings for your proxy.

For **Proxy configuration**, provide information for the following:

- **Proxy identifier.** Specify a name of your choosing, unique within your AWS account ID and current AWS Region.
- **Engine family.** This setting determines which database network protocol the proxy recognizes when it interprets network traffic to and from the database. For RDS for MariaDB or RDS for MySQL, choose **MySQL**. For RDS for PostgreSQL, choose **PostgreSQL**. For RDS for SQL Server, choose **SQL Server**.
- **Require Transport Layer Security.** Choose this setting if you want the proxy to enforce TLS/SSL for all client connections. For an encrypted or unencrypted connection to a proxy, the proxy uses the same encryption setting when it makes a connection to the underlying database.
- **Idle client connection timeout.** Choose a time period that a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes). A client connection is considered idle when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections.

Consider lowering the idle client connection timeout if you want the proxy to proactively remove stale connections. If your workload is spiking, consider raising the idle client connection timeout to save the cost of establishing connections.

For **Target group configuration**, provide information for the following:

- **Database.** Choose one RDS DB instance or Aurora DB cluster to access through this proxy. The list only includes DB instances and clusters with compatible database engines, engine versions, and other settings. If the list is empty, create a new DB instance or cluster that's compatible with RDS Proxy. To do so, follow the procedure in [Creating an Amazon RDS DB instance \(p. 230\)](#). Then try creating the proxy again.
- **Connection pool maximum connections.** Specify a value from 1 through 100. This setting represents the percentage of the `max_connections` value that RDS Proxy can use for its connections. If you only intend to use one proxy with this DB instance or cluster, you can set this value to 100. For details about how RDS Proxy uses this setting, see [MaxConnectionsPercent \(p. 947\)](#).
- **Session pinning filters.** (Optional) This is an advanced setting, for troubleshooting performance issues with particular applications. Currently, the setting isn't supported for PostgreSQL and the only choice is `EXCLUDE_VARIABLE_SETS`. Choose a filter only if both of following are true: First, your application isn't reusing connections due to certain kinds of SQL statements. Also, you can verify that reusing connections with those SQL statements doesn't affect application correctness. For more information, see [Avoiding pinning \(p. 948\)](#).
- **Connection borrow timeout.** In some cases, you might expect the proxy to sometimes use all available database connections. In such cases, you can specify how long the proxy waits for a database connection to become available before returning a timeout error. You can specify a period up to a maximum of five minutes. This setting only applies when the proxy has the maximum number of connections open and all connections are already in use.

- **Initialization query.** (Optional) You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with SET statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single SET statement, such as SET x=1, y=2. Initialization query is not currently supported for PostgreSQL.

For **Connectivity**, provide information for the following:

- **Secrets Manager secrets.** Choose at least one Secrets Manager secret that contains database user credentials for the RDS DB instance or Aurora DB cluster to access with this proxy.
- **IAM role.** Choose an IAM role that has permission to access the Secrets Manager secrets that you chose earlier. You can also choose for the AWS Management Console to create a new IAM role for you and use that.
- **IAM Authentication.** Choose whether to require, allow, or disallow IAM authentication for connections to your proxy. The allow option is only valid for proxies for RDS for SQL Server. The choice of IAM authentication or native database authentication applies to all DB users that access this proxy.
- **Subnets.** This field is prepopulated with all the subnets associated with your VPC. You can remove any subnets that you don't need for this proxy. You must leave at least two subnets.

Provide additional connectivity configuration:

- **VPC security group.** Choose an existing VPC security group. You can also choose for the AWS Management Console to create a new security group for you and use that.

Note

This security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group. When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see [Work with shared VPCs](#).

(Optional) Provide advanced configuration:

- **Enable enhanced logging.** You can enable this setting to troubleshoot proxy compatibility or performance issues.

When this setting is enabled, RDS Proxy includes detailed information about SQL statements in its logs. This information helps you to debug issues involving SQL behavior or the performance and scalability of the proxy connections. The debug information includes the text of SQL statements that you submit through the proxy. Thus, only enable this setting when needed for debugging. Also, only enable it when you have security measures in place to safeguard any sensitive information that appears in the logs.

To minimize overhead associated with your proxy, RDS Proxy automatically turns this setting off 24 hours after you enable it. Enable it temporarily to troubleshoot a specific issue.

5. Choose **Create Proxy**.

AWS CLI

To create a proxy, use the AWS CLI command [create-db-proxy](#). The `--engine-family` value is case-sensitive.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-proxy \
--db-proxy-name proxy_name \
--engine-family { MYSQL | POSTGRESQL | SQLSERVER } \
--auth ProxyAuthenticationConfig_JSON_string \
--role-arn iam_role \
--vpc-subnet-ids space_separated_list \
[--vpc-security-group-ids space_separated_list] \
[--require-tls | --no-require-tls] \
[--idle-client-timeout value] \
[--debug-logging | --no-debug-logging] \
[--tags comma_separated_list]
```

For Windows:

```
aws rds create-db-proxy ^
--db-proxy-name proxy_name ^
--engine-family { MYSQL | POSTGRESQL | SQLSERVER } ^
--auth ProxyAuthenticationConfig_JSON_string ^
--role-arn iam_role ^
--vpc-subnet-ids space_separated_list ^
[--vpc-security-group-ids space_separated_list] ^
[--require-tls | --no-require-tls] ^
[--idle-client-timeout value] ^
[--debug-logging | --no-debug-logging] ^
[--tags comma_separated_list]
```

Tip

If you don't already know the subnet IDs to use for the `--vpc-subnet-ids` parameter, see [Setting up network prerequisites \(p. 929\)](#) for examples of how to find them.

Note

The security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group.

When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see [Work with shared VPCs](#).

To create the required information and associations for the proxy, you also use the [register-db-proxy-targets](#) command. Specify the target group name `default`. RDS Proxy automatically creates a target group with this name when you create each proxy.

```
aws rds register-db-proxy-targets
--db-proxy-name value
[--target-group-name target_group_name]
[--db-instance-identifiers space_separated_list] # rds db instances, or
[--db-cluster-identifiers cluster_id]           # rds db cluster (all instances), or
[--db-cluster-endpoint endpoint_name]          # rds db cluster endpoint (all
instances)
```

RDS API

To create an RDS proxy, call the Amazon RDS API operation [CreateDBProxy](#). You pass a parameter with the [AuthConfig](#) data structure.

RDS Proxy automatically creates a target group named `default` when you create each proxy. You associate an RDS DB instance or Aurora DB cluster with the target group by calling the function [RegisterDBProxyTargets](#).

Viewing an RDS Proxy

After you create one or more RDS proxies, you can view them all. Doing so makes it possible to examine their configuration details and choose which ones to modify, delete, and so on.

Any database applications that use the proxy require the proxy endpoint to use in the connection string.

AWS Management Console

To view your proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the RDS Proxy.
3. In the navigation pane, choose **Proxies**.
4. Choose the name of an RDS proxy to display its details.
5. On the details page, the **Target groups** section shows how the proxy is associated with a specific RDS DB instance or Aurora DB cluster. You can follow the link to the **default** target group page to see more details about the association between the proxy and the database. This page is where you see settings that you specified when creating the proxy. These include maximum connection percentage, connection borrow timeout, engine family, and session pinning filters.

CLI

To view your proxy using the CLI, use the `describe-db-proxies` command. By default, it displays all proxies owned by your AWS account. To see details for a single proxy, specify its name with the `--db-proxy-name` parameter.

```
aws rds describe-db-proxies [--db-proxy-name proxy_name]
```

To view the other information associated with the proxy, use the following commands.

```
aws rds describe-db-proxy-target-groups --db-proxy-name proxy_name  
aws rds describe-db-proxy-targets --db-proxy-name proxy_name
```

Use the following sequence of commands to see more detail about the things that are associated with the proxy:

1. To get a list of proxies, run `describe-db-proxies`.
2. To show connection parameters such as the maximum percentage of connections that the proxy can use, run `describe-db-proxy-target-groups` `--db-proxy-name`. Use the name of the proxy as the parameter value.
3. To see the details of the RDS DB instance or Aurora DB cluster associated with the returned target group, run `describe-db-proxy-targets`.

RDS API

To view your proxies using the RDS API, use the [DescribeDBProxies](#) operation. It returns values of the [DBProxy](#) data type.

To see details of the connection settings for the proxy, use the proxy identifiers from this return value with the [DescribeDBProxyTargetGroups](#) operation. It returns values of the [DBProxyTargetGroup](#) data type.

To see the RDS instance or Aurora DB cluster associated with the proxy, use the [DescribeDBProxyTargets](#) operation. It returns values of the [DBProxyTarget](#) data type.

Connecting to a database through RDS Proxy

You connect to an RDS DB instance or Aurora DB cluster through a proxy in generally the same way as you connect directly to the database. The main difference is that you specify the proxy endpoint instead of the instance or cluster endpoint. For an Aurora DB cluster, by default all proxy connections have read/write capability and use the writer instance. If you normally use the reader endpoint for read-only connections, you can create an additional read-only endpoint for the proxy. You can use that endpoint the same way. For more information, see [Overview of proxy endpoints \(p. 953\)](#).

Topics

- [Connecting to a proxy using native authentication \(p. 939\)](#)
- [Connecting to a proxy using IAM authentication \(p. 940\)](#)
- [Considerations for connecting to a proxy with Microsoft SQL Server \(p. 940\)](#)
- [Considerations for connecting to a proxy with PostgreSQL \(p. 941\)](#)

Connecting to a proxy using native authentication

Use the following basic steps to connect to a proxy using native authentication:

1. Find the proxy endpoint. In the AWS Management Console, you can find the endpoint on the details page for the corresponding proxy. With the AWS CLI, you can use the [describe-db-proxies](#) command. The following example shows how.

```
# Add --output text to get output as a simple tab-separated list.
$ aws rds describe-db-proxies --query '*[*].{DBProxyName:DBProxyName,Endpoint:Endpoint}'
[
    [
        {
            "Endpoint": "the-proxy.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy"
        },
        {
            "Endpoint": "the-proxy-other-secret.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-other-secret"
        },
        {
            "Endpoint": "the-proxy-rds-secret.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-rds-secret"
        },
        {
            "Endpoint": "the-proxy-t3.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-t3"
        }
    ]
]
```

2. Specify that endpoint as the host parameter in the connection string for your client application. For example, specify the proxy endpoint as the value for the mysql -h option or psql -h option.
3. Supply the same database user name and password as you usually do.

Connecting to a proxy using IAM authentication

When you use IAM authentication with RDS Proxy, set up your database users to authenticate with regular user names and passwords. The IAM authentication applies to RDS Proxy retrieving the user name and password credentials from Secrets Manager. The connection from RDS Proxy to the underlying database doesn't go through IAM.

To connect to RDS Proxy using IAM authentication, use the same general connection procedure as for IAM authentication with an RDS DB instance or Aurora cluster. For general information about using IAM with RDS and Aurora, see [Security in Amazon RDS \(p. 1997\)](#).

The major differences in IAM usage for RDS Proxy include the following:

- You don't configure each individual database user with an authorization plugin. The database users still have regular user names and passwords within the database. You set up Secrets Manager secrets containing these user names and passwords, and authorize RDS Proxy to retrieve the credentials from Secrets Manager.

The IAM authentication applies to the connection between your client program and the proxy. The proxy then authenticates to the database using the user name and password credentials retrieved from Secrets Manager.

- Instead of the instance, cluster, or reader endpoint, you specify the proxy endpoint. For details about the proxy endpoint, see [Connecting to your DB instance using IAM authentication \(p. 2055\)](#).
- In the direct database IAM authentication case, you selectively choose database users and configure them to be identified with a special authentication plugin. You can then connect to those users using IAM authentication.

In the proxy use case, you provide the proxy with Secrets that contain some user's user name and password (native authentication). You then connect to the proxy using IAM authentication. Here, you do this by generating an authentication token with the proxy endpoint, not the database endpoint. You also use a user name that matches one of the user names for the secrets that you provided.

- Make sure that you use Transport Layer Security (TLS)/Secure Sockets Layer (SSL) when connecting to a proxy using IAM authentication.

You can grant a specific user access to the proxy by modifying the IAM policy. An example follows.

```
"Resource": "arn:aws:rds-db:us-east-2:1234567890:dbuser:px-ABCDEFGHIJKLM01234/db_user"
```

Considerations for connecting to a proxy with Microsoft SQL Server

For connecting to a proxy using IAM authentication, you don't use the password field. Instead, you provide the appropriate token property for each type of database driver in the token field. For example, use the accessToken property for JDBC, or the sql_copt_ss_access_token property for ODBC. Or use the AccessToken property for the .NET SqlClient driver. You can't use IAM authentication with clients that don't support token properties.

Under some conditions, a proxy can't share a database connection and instead pins the connection from your client application to the proxy to a dedicated database connection. For more information about these conditions, see [Avoiding pinning \(p. 948\)](#).

Considerations for connecting to a proxy with PostgreSQL

For PostgreSQL, when a client starts a connection to a PostgreSQL database, it sends a startup message. This message includes pairs of parameter name and value strings. For details, see the [StartupMessage](#) in [PostgreSQL message formats](#) in the PostgreSQL documentation.

When connecting through an RDS proxy, the startup message can include the following currently recognized parameters:

- `user`
- `database`
- `replication`

The startup message can also include the following additional runtime parameters:

- `application_name`
- `client_encoding`
- `DateStyle`
- `TimeZone`
- `extra_float_digits`

For more information about PostgreSQL messaging, see the [Frontend/Backend protocol](#) in the PostgreSQL documentation.

For PostgreSQL, if you use JDBC we recommend the following to avoid pinning:

- Set the JDBC connection parameter `assumeMinServerVersion` to at least `9.0` to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET extra_float_digits = 3`.
- Set the JDBC connection parameter `ApplicationName` to `any/your-application-name` to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET application_name = "PostgreSQL JDBC Driver"`. Note the JDBC parameter is `ApplicationName` but the PostgreSQL `StartupMessage` parameter is `application_name`.
- Set the JDBC connection parameter `preferQueryMode` to `extendedForPrepared` to avoid pinning. The `extendedForPrepared` ensures that the extended mode is used only for prepared statements.

The default for the `preferQueryMode` parameter is `extended`, which uses the extended mode for all queries. The extended mode uses a series of `Prepare`, `Bind`, `Execute`, and `Sync` requests and corresponding responses. This type of series causes connection pinning in an RDS proxy.

For more information, see [Avoiding pinning \(p. 948\)](#). For more information about connecting using JDBC, see [Connecting to the database](#) in the PostgreSQL documentation.

Managing an RDS Proxy

Following, you can find an explanation of how to manage RDS Proxy operation and configuration. These procedures help your application make the most efficient use of database connections and achieve maximum connection reuse. The more that you can take advantage of connection reuse, the more CPU and memory overhead that you can save. This in turn reduces latency for your application and enables the database to devote more of its resources to processing application requests.

Topics

- [Modifying an RDS Proxy \(p. 942\)](#)
- [Adding a new database user \(p. 946\)](#)
- [Changing the password for a database user \(p. 946\)](#)
- [Configuring connection settings \(p. 946\)](#)
- [Avoiding pinning \(p. 948\)](#)
- [Deleting an RDS Proxy \(p. 952\)](#)

Modifying an RDS Proxy

You can change certain settings associated with a proxy after you create the proxy. You do so by modifying the proxy itself, its associated target group, or both. Each proxy has an associated target group.

AWS Management Console

To modify the settings for a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list of proxies, choose the proxy whose settings you want to modify or go to its details page.
4. For **Actions**, choose **Modify**.
5. Enter or choose the properties to modify. You can modify the following:
 - **Proxy identifier** – Rename the proxy by entering a new identifier.
 - **Require Transport Layer Security** – Turn the requirement for Transport layer Security (TLS) on or off.
 - **Idle client connection timeout** – Enter a time period for the idle client connection timeout.
 - **Secrets Manager secrets** – Add or remove Secrets Manager secrets. These secrets correspond to database user names and passwords.
 - **IAM role** – Change the IAM role used to retrieve the secrets from Secrets Manager.
 - **IAM Authentication** – Require or disallow IAM authentication for connections to the proxy.
 - **VPC security group** – Add or remove VPC security groups for the proxy to use.
 - **Enable enhanced logging** – Enable or disable enhanced logging.
6. Choose **Modify**.

If you didn't find the settings listed that you want to change, use the following procedure to update the target group for the proxy. The *target group* associated with a proxy controls the settings related to the physical database connections. Each proxy has one associated target group named **default**, which is created automatically along with the proxy.

You can only modify the target group from the proxy details page, not from the list on the **Proxies** page.

To modify the settings for a proxy target group

1. On the **Proxies** page, go to the details page for a proxy.
2. For **Target groups**, choose the **default** link. Currently, all proxies have a single target group named **default**.
3. On the details page for the **default** target group, choose **Modify**.
4. Choose new settings for the properties that you can modify:

- **Database** – Choose a different RDS DB instance or Aurora cluster.
- **Connection pool maximum connections** – Adjust what percentage of the maximum available connections the proxy can use.
- **Session pinning filters** – (Optional) Choose a session pinning filter. Doing this can help reduce performance issues due to insufficient transaction-level reuse for connections. Using this setting requires understanding of application behavior and the circumstances under which RDS Proxy pins a session to a database connection. Currently, the setting isn't supported for PostgreSQL and the only choice is EXCLUDE_VARIABLE_SETS.
- **Connection borrow timeout** – Adjust the connection borrow timeout interval. This setting applies when the maximum number of connections is already being used for the proxy. The setting determines how long the proxy waits for a connection to become available before returning a timeout error.
- **Initialization query** – (Optional) Add an initialization query, or modify the current one. You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with SET statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single SET statement, such as SET x=1, y=2. Initialization query is not currently supported for PostgreSQL.

You can't change certain properties, such as the target group identifier and the database engine.

5. Choose **Modify target group**.

AWS CLI

To modify a proxy using the AWS CLI, use the commands [modify-db-proxy](#), [modify-db-proxy-target-group](#), [deregister-db-proxy-targets](#), and [register-db-proxy-targets](#).

With the `modify-db-proxy` command, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

The following example shows how to rename an existing proxy.

```
aws rds modify-db-proxy --db-proxy-name the-proxy --new-db-proxy-name the_new_name
```

To modify connection-related settings or rename the target group, use the `modify-db-proxy-target-group` command. Currently, all proxies have a single target group named default. When working with this target group, you specify the name of the proxy and default for the name of the target group.

The following example shows how to first check the `MaxIdleConnectionsPercent` setting for a proxy and then change it, using the target group.

```
aws rds describe-db-proxy-target-groups --db-proxy-name the-proxy
{
    "TargetGroups": [
```

```
{
    "Status": "available",
    "UpdatedDate": "2019-11-30T16:49:30.342Z",
    "ConnectionPoolConfig": {
        "MaxIdleConnectionsPercent": 50,
        "ConnectionBorrowTimeout": 120,
        "MaxConnectionsPercent": 100,
        "SessionPinningFilters": []
    },
    "TargetGroupName": "default",
    "CreatedDate": "2019-11-30T16:49:27.940Z",
    "DBProxyName": "the-proxy",
    "IsDefault": true
}
]

}

aws rds modify-db-proxy-target-group --db-proxy-name the-proxy --target-group-name default
--connection-pool-config '
{ "MaxIdleConnectionsPercent": 75 }'

{
    "DBProxyTargetGroup": {
        "Status": "available",
        "UpdatedDate": "2019-12-02T04:09:50.420Z",
        "ConnectionPoolConfig": {
            "MaxIdleConnectionsPercent": 75,
            "ConnectionBorrowTimeout": 120,
            "MaxConnectionsPercent": 100,
            "SessionPinningFilters": []
        },
        "TargetGroupName": "default",
        "CreatedDate": "2019-11-30T16:49:27.940Z",
        "DBProxyName": "the-proxy",
        "IsDefault": true
    }
}
```

With the `deregister-db-proxy-targets` and `register-db-proxy-targets` commands, you change which RDS DB instance or Aurora DB cluster the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance or Aurora DB cluster. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration. Or the target group tracks the connection details for all the DB instances in an Aurora cluster.

The following example starts with a proxy that is associated with an Aurora MySQL cluster named `cluster-56-2020-02-25-1399`. The example shows how to change the proxy so that it can connect to a different cluster named `provisioned-cluster`.

When you work with an RDS DB instance, you specify the `--db-instance-identifier` option. When you work with an Aurora DB cluster, you specify the `--db-cluster-identifier` option instead.

The following example modifies an Aurora MySQL proxy. An Aurora PostgreSQL proxy has port 5432.

```
aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": [
        {
            "Endpoint": "instance-9814.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-9814"
        },
        {

```

```

        "Endpoint": "instance-8898.demo.us-east-1.rds.amazonaws.com",
        "Type": "RDS_INSTANCE",
        "Port": 3306,
        "RdsResourceId": "instance-8898"
    },
    {
        "Endpoint": "instance-1018.demo.us-east-1.rds.amazonaws.com",
        "Type": "RDS_INSTANCE",
        "Port": 3306,
        "RdsResourceId": "instance-1018"
    },
    {
        "Type": "TRACKED_CLUSTER",
        "Port": 0,
        "RdsResourceId": "cluster-56-2020-02-25-1399"
    },
    {
        "Endpoint": "instance-4330.demo.us-east-1.rds.amazonaws.com",
        "Type": "RDS_INSTANCE",
        "Port": 3306,
        "RdsResourceId": "instance-4330"
    }
]
}

aws rds deregister-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
cluster-56-2020-02-25-1399

aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": []
}

aws rds register-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
provisioned-cluster

{
    "DBProxyTargets": [
        {
            "Type": "TRACKED_CLUSTER",
            "Port": 0,
            "RdsResourceId": "provisioned-cluster"
        },
        {
            "Endpoint": "gkldje.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "gkldje"
        },
        {
            "Endpoint": "provisioned-1.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "provisioned-1"
        }
    ]
}

```

RDS API

To modify a proxy using the RDS API, you use the operations [ModifyDBProxy](#), [ModifyDBProxyTargetGroup](#), [DeregisterDBProxyTargets](#), and [RegisterDBProxyTargets](#) operations.

With [ModifyDBProxy](#), you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

With `ModifyDBProxyTargetGroup`, you can modify connection-related settings or rename the target group. Currently, all proxies have a single target group named `default`. When working with this target group, you specify the name of the proxy and `default` for the name of the target group.

With `DeregisterDBProxyTargets` and `RegisterDBProxyTargets`, you change which RDS DB instance or Aurora DB cluster the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance or Aurora DB cluster. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration, or all the DB instances in an Aurora cluster.

Adding a new database user

In some cases, you might add a new database user to an RDS DB instance or Aurora cluster that's associated with a proxy. If so, add or repurpose a Secrets Manager secret to store the credentials for that user. To do this, choose one of the following options:

- Create a new Secrets Manager secret, using the procedure described in [Setting up database credentials in AWS Secrets Manager \(p. 931\)](#).
- Update the IAM role to give RDS Proxy access to the new Secrets Manager secret. To do so, update the resources section of the IAM role policy.
- If the new user takes the place of an existing one, update the credentials stored in the proxy's Secrets Manager secret for the existing user.

Changing the password for a database user

In some cases, you might change the password for a database user in an RDS DB instance or Aurora cluster that's associated with a proxy. If so, update the corresponding Secrets Manager secret with the new password.

Configuring connection settings

To adjust RDS Proxy's connection pooling, you can modify the following settings:

- [IdleClientTimeout \(p. 946\)](#)
- [MaxConnectionsPercent \(p. 947\)](#)
- [MaxIdleConnectionsPercent \(p. 947\)](#)
- [ConnectionBorrowTimeout \(p. 947\)](#)

IdleClientTimeout

You can specify how long a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes).

A client connection is considered *idle* when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections. If

you want the proxy to proactively remove stale connections, consider lowering the idle client connection timeout. If your workload establishes frequent connections with the proxy, consider raising the idle client connection timeout to save the cost of establishing connections.

This setting is represented by the **Idle client connection timeout** field in the RDS console and the `IdleClientTimeout` setting in the AWS CLI and the API. To learn how to change the value of the **Idle client connection timeout** field in the RDS console, see [AWS Management Console \(p. 942\)](#). To learn how to change the value of the `IdleClientTimeout` setting, see the CLI command [modify-db-proxy](#) or the API operation [ModifyDBProxy](#).

MaxConnectionsPercent

You can limit the number of connections that an RDS Proxy can establish with the database. You specify the limit as a percentage of the maximum connections available for your database. The proxy doesn't create all of these connections in advance. This setting reserves the right for the proxy to establish these connections as the workload needs them.

For example, suppose that you configured RDS Proxy to use 75 percent of the maximum connections for your database. In this case, your database supports a maximum of 1,000 concurrent connections. Here, RDS Proxy can open up to 750 database connections.

This setting is represented by the **Connection pool maximum connections** field in the RDS console and the `MaxConnectionsPercent` setting in the AWS CLI and the API. To learn how to change the value of the **Connection pool maximum connections** field in the RDS console, see [AWS Management Console \(p. 942\)](#). To learn how to change the value of the `MaxConnectionsPercent` setting, see the CLI command [modify-db-proxy-target-group](#) or the API operation [ModifyDBProxyTargetGroup](#).

For information on database connection limits, see [Maximum number of database connections](#).

MaxIdleConnectionsPercent

You can control the number of idle database connections that RDS Proxy can keep in the connection pool. RDS Proxy considers a database connection in its pool to be *idle* when there's been no activity on the connection for five minutes.

You specify the limit as a percentage of the maximum connections available for your database. The default value is 50 percent of `MaxConnectionsPercent`, and the upper limit is the value of `MaxConnectionsPercent`. With a high value, the proxy leaves a high percentage of idle database connections open. With a low value, the proxy closes a high percentage of idle database connections. If your workloads are unpredictable, consider setting a high value for `MaxIdleConnectionsPercent`. Doing so means that RDS Proxy can accommodate surges in activity without opening a lot of new database connections.

This setting is represented by the `MaxIdleConnectionsPercent` setting of `DBProxyTargetGroup` in the AWS CLI and the API. To learn how to change the value of the `MaxIdleConnectionsPercent` setting, see the CLI command [modify-db-proxy-target-group](#) or the API operation [ModifyDBProxyTargetGroup](#).

Note

RDS Proxy closes database connections some time after 24 hours when they are no longer in use. The proxy performs this action regardless of the value of the maximum idle connections setting.

For information on database connection limits, see [Maximum number of database connections](#).

ConnectionBorrowTimeout

You can choose how long RDS Proxy waits for a database connection in the connection pool to become available for use before returning a timeout error. The default is 120 seconds. This setting applies when

the number of connections is at the maximum, and so no connections are available in the connection pool. It also applies if no appropriate database instance is available to handle the request because, for example, a failover operation is in process. Using this setting, you can set the best wait period for your application without having to change the query timeout in your application code.

This setting is represented by the **Connection borrow timeout** field in the RDS console or the `ConnectionBorrowTimeout` setting of `DBProxyTargetGroup` in the AWS CLI or API. To learn how to change the value of the **Connection borrow timeout** field in the RDS console, see [AWS Management Console \(p. 942\)](#). To learn how to change the value of the `ConnectionBorrowTimeout` setting, see the CLI command `modify-db-proxy-target-group` or the API operation `ModifyDBProxyTargetGroup`.

Avoiding pinning

Multiplexing is more efficient when database requests don't rely on state information from previous requests. In that case, RDS Proxy can reuse a connection at the conclusion of each transaction. Examples of such state information include most variables and configuration parameters that you can change through `SET` or `SELECT` statements. SQL transactions on a client connection can multiplex between underlying database connections by default.

Your connections to the proxy can enter a state known as *pinning*. When a connection is pinned, each later transaction uses the same underlying database connection until the session ends. Other client connections also can't reuse that database connection until the session ends. The session ends when the client connection is dropped.

RDS Proxy automatically pins a client connection to a specific DB connection when it detects a session state change that isn't appropriate for other sessions. Pinning reduces the effectiveness of connection reuse. If all or almost all of your connections experience pinning, consider modifying your application code or workload to reduce the conditions that cause the pinning.

For example, suppose that your application changes a session variable or configuration parameter. In this case, later statements can rely on the new variable or parameter to be in effect. Thus, when RDS Proxy processes requests to change session variables or configuration settings, it pins that session to the DB connection. That way, the session state remains in effect for all later transactions in the same session.

For some database engines, this rule doesn't apply to all parameters that you can set. RDS Proxy tracks certain statements and variables. Thus RDS Proxy doesn't pin the session when you modify them. In this case, RDS Proxy only reuses the connection for other sessions that have the same values for those settings. For details about what RDS Proxy tracks for a database engine, see the following:

- [What RDS Proxy tracks for RDS for SQL Server databases \(p. 948\)](#)
- [What RDS Proxy tracks for RDS for MariaDB and RDS for MySQL databases \(p. 949\)](#)

What RDS Proxy tracks for RDS for SQL Server databases

Following are the SQL Server statements that RDS Proxy tracks:

- `USE`
- `SET ANSI_NULLS`
- `SET ANSI_PADDING`
- `SET ANSI_WARNINGS`
- `SET ARITHABORT`
- `SET CONCAT_NULL_YIELDS_NULL`
- `SET CURSOR_CLOSE_ON_COMMIT`
- `SET DATEFIRST`

- SET DATEFORMAT
- SET LANGUAGE
- SET LOCK_TIMEOUT
- SET NUMERIC_ROUNDABORT
- SET QUOTED_IDENTIFIER
- SET TEXTSIZE
- SET TRANSACTION ISOLATION LEVEL

What RDS Proxy tracks for RDS for MariaDB and RDS for MySQL databases

Following are the MySQL and MariaDB statements that RDS Proxy tracks:

- DROP DATABASE
- DROP SCHEMA
- USE

Following are the MySQL and MariaDB variables that RDS Proxy tracks:

- AUTOCOMMIT
- AUTO_INCREMENT_INCREMENT
- CHARACTER_SET (or CHAR_SET)
- CHARACTER_SET_CLIENT
- CHARACTER_SET_DATABASE
- CHARACTER_SET_FILESYSTEM
- CHARACTER_SET_CONNECTION
- CHARACTER_SET_RESULTS
- CHARACTER_SET_SERVER
- COLLATION_CONNECTION
- COLLATION_DATABASE
- COLLATION_SERVER
- INTERACTIVE_TIMEOUT
- NAMES
- NET_WRITE_TIMEOUT
- QUERY_CACHE_TYPE
- SESSION_TRACK_SCHEMA
- SQL_MODE
- TIME_ZONE
- TRANSACTION_ISOLATION (or TX_ISOLATION)
- TRANSACTION_READ_ONLY (or TX_READ_ONLY)
- WAIT_TIMEOUT

Minimizing pinning

Performance tuning for RDS Proxy involves trying to maximize transaction-level connection reuse (multiplexing) by minimizing pinning.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called *pinning*.

You can minimize pinning by doing the following:

- Avoid unnecessary database requests that might cause pinning.
- Set variables and configuration settings consistently across all connections. That way, later sessions are more likely to reuse connections that have those particular settings.

However, for PostgreSQL setting a variable leads to session pinning.

- For a MySQL engine family database, apply a session pinning filter to the proxy. You can exempt certain kinds of operations from pinning the session if you know that doing so doesn't affect the correct operation of your application.
- See how frequently pinning occurs by monitoring the Amazon CloudWatch metric `DatabaseConnectionsCurrentlySessionPinned`. For information about this and other CloudWatch metrics, see [Monitoring RDS Proxy metrics with Amazon CloudWatch \(p. 959\)](#).
- If you use SET statements to perform identical initialization for each client connection, you can do so while preserving transaction-level multiplexing. In this case, you move the statements that set up the initial session state into the initialization query used by a proxy. This property is a string containing one or more SQL statements, separated by semicolons.

For example, you can define an initialization query for a proxy that sets certain configuration parameters. Then, RDS Proxy applies those settings whenever it sets up a new connection for that proxy. You can remove the corresponding SET statements from your application code, so that they don't interfere with transaction-level multiplexing.

For metrics about how often pinning occurs for a proxy, see [Monitoring RDS Proxy metrics with Amazon CloudWatch \(p. 959\)](#).

Conditions that cause pinning for all engine families

The proxy pins the session to the current connection in the following situations where multiplexing might cause unexpected behavior:

- Any statement with a text size greater than 16 KB causes the proxy to pin the session.
- Prepared statements cause the proxy to pin the session. This rule applies whether the prepared statement uses SQL text or the binary protocol.

Conditions that cause pinning for RDS for Microsoft SQL Server

For RDS for SQL Server, the following interactions also cause pinning:

- Using multiple active result sets (MARS). For information about MARS, see the [SQL Server documentation](#).
- Using distributed transaction coordinator (DTC) communication.
- Creating temporary tables, transactions, cursors, or prepared statements.
- Using the following SET statements:
 - SET ANSI_DEFAULTS
 - SET ANSI_NULL_DFLT
 - SET ARITHIGNORE
 - SET DEADLOCK_PRIORITY
 - SET FIPS_FLAGGER

- SET FMTONLY
- SET FORCEPLAN
- SET IDENTITY_INSERT
- SET NOCOUNT
- SET NOEXEC
- SET OFFSETS
- SET PARSEONLY
- SET QUERY_GOVERNOR_COST_LIMIT
- SET REMOTE_PROC_TRANSACTIONS
- SET ROWCOUNT
- SET SHOWPLAN_ALL, SHOWPLAN_TEXT, and SHOWPLAN_XML
- SET STATISTICS
- SET XACT_ABORT

Conditions that cause pinning for RDS for MariaDB and RDS for MySQL

For MySQL and MariaDB, the following interactions also cause pinning:

- Explicit table lock statements LOCK TABLE, LOCK TABLES, or FLUSH TABLES WITH READ LOCK cause the proxy to pin the session.
- Creating named locks by using GET_LOCK causes the proxy to pin the session.
- Setting a user variable or a system variable (with some exceptions) causes the proxy to pin the session. If this situation reduces your connection reuse too much, you can choose for SET operations not to cause pinning. For information about how to do so by setting the session pinning filters property, see [Creating an RDS Proxy \(p. 934\)](#) and [Modifying an RDS Proxy \(p. 942\)](#).
- Creating a temporary table causes the proxy to pin the session. That way, the contents of the temporary table are preserved throughout the session regardless of transaction boundaries.
- Calling the functions ROW_COUNT, FOUND_ROWS, and LAST_INSERT_ID sometimes causes pinning.

Calling stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Therefore, make sure that your application doesn't change session state inside stored routines and rely on that session state to persist across transactions. For example, if a stored procedure creates a temporary table that is intended to persist across transactions, that application currently isn't compatible with RDS Proxy.

If you have expert knowledge about your application behavior, you can skip the pinning behavior for certain application statements. To do so, choose the **Session pinning filters** option when creating the proxy. Currently, you can opt out of session pinning for setting session variables and configuration settings.

Conditions that cause pinning for RDS for PostgreSQL

For PostgreSQL, the following interactions also cause pinning:

- Using SET commands
- Using the PostgreSQL extended query protocol such as by using JDBC default settings
- Creating temporary sequences, tables, or views
- Declaring cursors
- Discarding the session state

- Listening on a notification channel
- Loading a library module such as auto_explain
- Manipulating sequences using functions such as nextval and setval
- Interacting with locks using functions such as pg_advisory_lock and pg_try_advisory_lock
- Using prepared statements, setting parameters, or resetting a parameter to its default

Deleting an RDS Proxy

You can delete a proxy if you no longer need it. You might delete a proxy because the application that was using it is no longer relevant. Or you might delete a proxy if you take the DB instance or cluster associated with it out of service.

AWS Management Console

To delete a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Choose the proxy to delete from the list.
4. Choose **Delete Proxy**.

AWS CLI

To delete a DB proxy, use the AWS CLI command `delete-db-proxy`. To remove related associations, also use the `deregister-db-proxy-targets` command.

```
aws rds delete-db-proxy --name proxy_name
```

```
aws rds deregister-db-proxy-targets
  --db-proxy-name proxy_name
  [--target-group-name target_group_name]
  [--target-ids comma_separated_list]      # or
  [--db-instance-identifiers instance_id]      # or
  [--db-cluster-identifiers cluster_id]
```

RDS API

To delete a DB proxy, call the Amazon RDS API function `DeleteDBProxy`. To delete related items and associations, you also call the functions `DeleteDBProxyTargetGroup` and `DeregisterDBProxyTargets`.

Working with Amazon RDS Proxy endpoints

Following, you can learn about endpoints for RDS Proxy and how to use them. By using endpoints, you can take advantage of the following capabilities:

- You can use multiple endpoints with a proxy to monitor and troubleshoot connections from different applications independently.
- You can use reader endpoints with Aurora DB clusters to improve read scalability and high availability for your query-intensive applications.
- You can use a cross-VPC endpoint to allow access to databases in one VPC from resources such as Amazon EC2 instances in a different VPC.

Topics

- [Overview of proxy endpoints \(p. 953\)](#)
- [Reader endpoints \(p. 953\)](#)
- [Accessing Aurora and RDS databases across VPCs \(p. 954\)](#)
- [Creating a proxy endpoint \(p. 954\)](#)
- [Viewing proxy endpoints \(p. 956\)](#)
- [Modifying a proxy endpoint \(p. 957\)](#)
- [Deleting a proxy endpoint \(p. 958\)](#)
- [Limitations for proxy endpoints \(p. 959\)](#)

Overview of proxy endpoints

Working with RDS Proxy endpoints involves the same kinds of procedures as with Aurora DB cluster and reader endpoints and RDS instance endpoints. If you aren't familiar with RDS endpoints, find more information in [Connecting to a DB instance running the MySQL database engine](#) and [Connecting to a DB instance running the PostgreSQL database engine](#).

By default, the endpoint that you connect to when you use RDS Proxy with an Aurora cluster has read/write capability. As a result, this endpoint sends all requests to the writer instance of the cluster. All of those connections count against the `max_connections` value for the writer instance. If your proxy is associated with an Aurora DB cluster, you can create additional read/write or read-only endpoints for that proxy.

You can use a read-only endpoint with your proxy for read-only queries. You do this the same way that you use the reader endpoint for an Aurora provisioned cluster. Doing so helps you to take advantage of the read scalability of an Aurora cluster with one or more reader DB instances. You can run more simultaneous queries and make more simultaneous connections by using a read-only endpoint and adding more reader DB instances to your Aurora cluster as needed.

For a proxy endpoint that you create, you can also associate the endpoint with a different virtual private cloud (VPC) than the proxy itself uses. By doing so, you can connect to the proxy from a different VPC, for example a VPC used by a different application within your organization.

For information about limits associated with proxy endpoints, see [Limitations for proxy endpoints \(p. 959\)](#).

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint. Or it can be the special name `default` for read/write requests using the default endpoint of a proxy.

Each proxy endpoint has its own set of CloudWatch metrics. You can monitor the metrics for all endpoints of a proxy. You can also monitor metrics for a specific endpoint, or for all the read/write or read-only endpoints of a proxy. For more information, see [Monitoring RDS Proxy metrics with Amazon CloudWatch \(p. 959\)](#).

A proxy endpoint uses the same authentication mechanism as its associated proxy. RDS Proxy automatically sets up permissions and authorizations for the user-defined endpoint, consistent with the properties of the associated proxy.

Reader endpoints

With RDS Proxy, you can create and use reader endpoints. However, these endpoints only work for proxies associated with Aurora DB clusters. You might see references to reader endpoints in the AWS

Management Console. If you use the RDS CLI or API, you might see the `TargetRole` attribute with a value of `READ_ONLY`. You can take advantage of these features by changing the target of a proxy from an RDS DB instance to an Aurora DB cluster. To learn about reader endpoints, see [Managing connections with Amazon RDS Proxy](#) in the *Aurora User Guide*.

Accessing Aurora and RDS databases across VPCs

By default, the components of your RDS and Aurora technology stack are all in the same Amazon VPC. For example, suppose that an application running on an Amazon EC2 instance connects to an Amazon RDS DB instance or an Aurora DB cluster. In this case, the application server and database must both be within the same VPC.

With RDS Proxy, you can set up access to an Aurora cluster or RDS instance in one VPC from resources such as EC2 instances in another VPC. For example, your organization might have multiple applications that access the same database resources. Each application might be in its own VPC.

To enable cross-VPC access, you create a new endpoint for the proxy. If you aren't familiar with creating proxy endpoints, see [Working with Amazon RDS Proxy endpoints \(p. 952\)](#) for details. The proxy itself resides in the same VPC as the Aurora DB cluster or RDS instance. However, the cross-VPC endpoint resides in the other VPC, along with the other resources such as the EC2 instances. The cross-VPC endpoint is associated with subnets and security groups from the same VPC as the EC2 and other resources. These associations let you connect to the endpoint from the applications that otherwise can't access the database due to the VPC restrictions.

The following steps explain how to create and access a cross-VPC endpoint through RDS Proxy:

1. Create two VPCs, or choose two VPCs that you already use for Aurora and RDS work. Each VPC should have its own associated network resources such as an Internet gateway, route tables, subnets, and security groups. If you only have one VPC, you can consult [Getting started with Amazon RDS \(p. 153\)](#) for the steps to set up another VPC to use RDS successfully. You can also examine your existing VPC in the Amazon EC2 console to see what kinds of resources to connect together.
2. Create a DB proxy associated with the Aurora DB cluster or RDS instance that you want to connect to. Follow the procedure in [Creating an RDS Proxy \(p. 934\)](#).
3. On the **Details** page for your proxy in the RDS console, under the **Proxy endpoints** section, choose **Create endpoint**. Follow the procedure in [Creating a proxy endpoint \(p. 954\)](#).
4. Choose whether to make the cross-VPC endpoint read/write or read-only.
5. Instead of accepting the default of the same VPC as the Aurora DB cluster or RDS instance, choose a different VPC. This VPC must be in the same AWS Region as the VPC where the proxy resides.
6. Now instead of accepting the defaults for subnets and security groups from the same VPC as the Aurora DB cluster or RDS instance, make new selections. Make these based on the subnets and security groups from the VPC that you chose.
7. You don't need to change any of the settings for the Secrets Manager secrets. The same credentials work for all endpoints for your proxy, regardless of which VPC each endpoint is in.
8. Wait for the new endpoint to reach the **Available** state.
9. Make a note of the full endpoint name. This is the value ending in `Region_name.rds.amazonaws.com` that you supply as part of the connection string for your database application.
10. Access the new endpoint from a resource in the same VPC as the endpoint. A simple way to test this process is to create a new EC2 instance in this VPC. Then you can log into the EC2 instance and run the `mysql` or `psql` commands to connect by using the endpoint value in your connection string.

Creating a proxy endpoint

Console

To create a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Click the name of the proxy that you want to create a new endpoint for.

The details page for that proxy appears.

4. In the **Proxy endpoints** section, choose **Create proxy endpoint**.

The **Create proxy endpoint** window appears.

5. For **Proxy endpoint name**, enter a descriptive name of your choice.
6. For **Target role**, choose whether to make the endpoint read/write or read-only.

Connections that use a read/write endpoint can perform any kind of operation: data definition language (DDL) statements, data manipulation language (DML) statements, and queries. These endpoints always connect to the primary instance of the Aurora cluster. You can use read/write endpoints for general database operations when you only use a single endpoint in your application. You can also use read/write endpoints for administrative operations, online transaction processing (OLTP) applications, and extract-transform-load (ETL) jobs.

Connections that use a read-only endpoint can only perform queries. When there are multiple reader instances in the Aurora cluster, RDS Proxy can use a different reader instance for each connection to the endpoint. That way, a query-intensive application can take advantage of Aurora's clustering capability. You can add more query capacity to the cluster by adding more reader DB instances. These read-only connections don't impose any overhead on the primary instance of the cluster. That way, your reporting and analysis queries don't slow down the write operations of your OLTP applications.

7. For **Virtual Private Cloud (VPC)**, choose the default to access the endpoint from the same EC2 instances or other resources where you normally access the proxy or its associated database. To set up cross-VPC access for this proxy, choose a VPC other than the default. For more information about cross-VPC access, see [Accessing Aurora and RDS databases across VPCs \(p. 954\)](#).
8. For **Subnets**, RDS Proxy fills in the same subnets as the associated proxy by default. To restrict access to the endpoint so only a portion of the VPC's address range can connect to it, remove one or more subnets.
9. For **VPC security group**, you can choose an existing security group or create a new one. RDS Proxy fills in the same security group or groups as the associated proxy by default. If the inbound and outbound rules for the proxy are appropriate for this endpoint, you can leave the default choice.

If you choose to create a new security group, specify a name for the security group on this page. Then edit the security group settings from the EC2 console afterward.

10. Choose **Create proxy endpoint**.

AWS CLI

To create a proxy endpoint, use the AWS CLI [create-db-proxy-endpoint](#) command.

Include the following required parameters:

- `--db-proxy-name value`
- `--db-proxy-endpoint-name value`
- `--vpc-subnet-ids list_of_ids`. Separate the subnet IDs with spaces. You don't specify the ID of the VPC itself.

You can also include the following optional parameters:

- `--target-role` { READ_WRITE | READ_ONLY }. This parameter defaults to READ_WRITE. The READ_ONLY value only has an effect on Aurora provisioned clusters that contain one or more reader DB instances. When the proxy is associated with an RDS instance or with an Aurora cluster that only contains a writer DB instance, you can't specify READ_ONLY.
- `--vpc-security-group-ids` *value*. Separate the security group IDs with spaces. If you omit this parameter, RDS Proxy uses the default security group for the VPC. RDS Proxy determines the VPC based on the subnet IDs that you specify for the `--vpc-subnet-ids` parameter.

Example

The following example creates a proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds create-db-proxy-endpoint \
--db-proxy-name my-proxy \
--db-proxy-endpoint-name my-endpoint \
--vpc-subnet-ids subnet_id subnet_id subnet_id ... \
--target-role READ_ONLY \
--vpc-security-group-ids security_group_id ]
```

For Windows:

```
aws rds create-db-proxy-endpoint ^
--db-proxy-name my-proxy ^
--db-proxy-endpoint-name my-endpoint ^
--vpc-subnet-ids subnet_id_1 subnet_id_2 subnet_id_3 ... ^
--target-role READ_ONLY ^
--vpc-security-group-ids security_group_id
```

RDS API

To create a proxy endpoint, use the RDS API [CreateProxyEndpoint](#) action.

Viewing proxy endpoints

Console

To view the details for a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to view. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to view. Click its name to view the details page.
5. Examine the parameters whose values you're interested in. You can check properties such as the following:
 - Whether the endpoint is read/write or read-only.
 - The endpoint address that you use in a database connection string.
 - The VPC, subnets, and security groups associated with the endpoint.

AWS CLI

To view one or more DB proxy endpoints, use the AWS CLI [describe-db-proxy-endpoints](#) command.

You can include the following optional parameters:

- `--db-proxy-endpoint-name`
- `--db-proxy-name`

The following example describes the `my-endpoint` proxy endpoint.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-proxy-endpoints \
--db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds describe-db-proxy-endpoints ^
--db-proxy-endpoint-name my-endpoint
```

RDS API

To describe one or more proxy endpoints, use the RDS API [DescribeDBProxyEndpoints](#) operation.

Modifying a proxy endpoint

Console

To modify one or more proxy endpoints

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to modify. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to modify. You can select it in the list, or click its name to view the details page.
5. On the proxy details page, under the **Proxy endpoints** section, choose **Edit**. Or on the proxy endpoint details page, for **Actions**, choose **Edit**.
6. Change the values of the parameters that you want to modify.
7. Choose **Save changes**.

AWS CLI

To modify a DB proxy endpoint, use the AWS CLI [modify-db-proxy-endpoint](#) command with the following required parameters:

- `--db-proxy-endpoint-name`

Specify changes to the endpoint properties by using one or more of the following parameters:

- `--new-db-proxy-endpoint-name`
- `--vpc-security-group-ids`. Separate the security group IDs with spaces.

The following example renames the `my-endpoint` proxy endpoint to `new-endpoint-name`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-proxy-endpoint \
--db-proxy-endpoint-name my-endpoint \
--new-db-proxy-endpoint-name new-endpoint-name
```

For Windows:

```
aws rds modify-db-proxy-endpoint ^
--db-proxy-endpoint-name my-endpoint ^
--new-db-proxy-endpoint-name new-endpoint-name
```

RDS API

To modify a proxy endpoint, use the RDS API [ModifyDBProxyEndpoint](#) operation.

Deleting a proxy endpoint

You can delete an endpoint for your proxy using the console as described following.

Note

You can't delete the default endpoint that RDS Proxy automatically creates for each proxy.
When you delete a proxy, RDS Proxy automatically deletes all the associated endpoints.

Console

To delete a proxy endpoint using the AWS Management Console

1. In the navigation pane, choose **Proxies**.
2. In the list, choose the proxy whose endpoint you want to endpoint. Click the proxy name to view its details page.
3. In the **Proxy endpoints** section, choose the endpoint that you want to delete. You can select one or more endpoints in the list, or click the name of a single endpoint to view the details page.
4. On the proxy details page, under the **Proxy endpoints** section, choose **Delete**. Or on the proxy endpoint details page, for **Actions**, choose **Delete**.

AWS CLI

To delete a proxy endpoint, run the `delete-db-proxy-endpoint` command with the following required parameters:

- `--db-proxy-endpoint-name`

The following command deletes the proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds delete-db-proxy-endpoint \
--db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds delete-db-proxy-endpoint ^
--db-proxy-endpoint-name my-endpoint
```

RDS API

To delete a proxy endpoint with the RDS API, run the [DeleteDBProxyEndpoint](#) operation. Specify the name of the proxy endpoint for the DBProxyEndpointName parameter.

Limitations for proxy endpoints

Each proxy has a default endpoint that you can modify but not create or delete.

The maximum number of user-defined endpoints for a proxy is 20. Thus, a proxy can have up to 21 endpoints: the default endpoint, plus 20 that you create.

When you associate additional endpoints with a proxy, RDS Proxy automatically determines which DB instances in your cluster to use for each endpoint. You can't choose specific instances the way that you can with Aurora custom endpoints.

Reader endpoints aren't available for Aurora multi-writer clusters.

Monitoring RDS Proxy metrics with Amazon CloudWatch

You can monitor RDS Proxy by using Amazon CloudWatch. CloudWatch collects and processes raw data from the proxies into readable, near-real-time metrics. To find these metrics in the CloudWatch console, choose **Metrics**, then choose **RDS**, and choose **Per-Proxy Metrics**. For more information, see [Using Amazon CloudWatch metrics](#) in the Amazon CloudWatch User Guide.

Note

RDS publishes these metrics for each underlying Amazon EC2 instance associated with a proxy. A single proxy might be served by more than one EC2 instance. Use CloudWatch statistics to aggregate the values for a proxy across all the associated instances.

Some of these metrics might not be visible until after the first successful connection by a proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for read/write requests using the default endpoint of a proxy.

All RDS Proxy metrics are in the group `proxy`.

Each proxy endpoint has its own CloudWatch metrics. You can monitor the usage of each proxy endpoint independently. For more information about proxy endpoints, see [Working with Amazon RDS Proxy endpoints \(p. 952\)](#).

You can aggregate the values for each metric using one of the following dimension sets. For example, by using the `ProxyName` dimension set, you can analyze all the traffic for a particular proxy. By using the other dimension sets, you can split the metrics in different ways. You can split the metrics based on

the different endpoints or target databases of each proxy, or the read/write and read-only traffic to each database.

- Dimension set 1: ProxyName
- Dimension set 2: ProxyName, EndpointName
- Dimension set 3: ProxyName, TargetGroup, Target
- Dimension set 4: ProxyName, TargetGroup, TargetRole

Metric	Description	Valid period	CloudWatch dimension set
AvailabilityPercentage	The percentage of time for which the target group was available in the role indicated by the dimension. This metric is reported every minute. The most useful statistic for this metric is Average.	1 minute	Dimension set 4 (p. 960)
ClientConnections	The current number of client connections. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 960) , Dimension set 2 (p. 960)
ClientConnectionsClosed	The number of client connections closed. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 2 (p. 960)
ClientConnectionsNotEstablished	The current number of client connections without Transport Layer Security (TLS). This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 2 (p. 960)
ClientConnectionsReceived	The number of client connection requests received. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 2 (p. 960)
ClientConnectionsRejected	The number of client connection attempts that failed due to misconfigured authentication or TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 2 (p. 960)

Metric	Description	Valid period	CloudWatch dimension set
ClientConnectionsSet	The number of client connections successfully established with any authentication mechanism with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 2 (p. 960)
ClientConnectionsTLS	The current number of client connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 2 (p. 960)
DatabaseConnectionRequests	The number of requests to create a database connection. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 3 (p. 960) , Dimension set 4 (p. 960)
DatabaseConnectionRequestsTLS	The number of requests to create a database connection with TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 3 (p. 960) , Dimension set 4 (p. 960)
DatabaseConnections	The current number of database connections. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 960) , Dimension set 3 (p. 960) , Dimension set 4 (p. 960)
DatabaseConnectionsBorrowLatency	The total latency microseconds that it takes for the proxy being monitored to get a database connection. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 2 (p. 960)
DatabaseConnectionsBorrowed	The current number of database connections in the borrow state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 960) , Dimension set 3 (p. 960) , Dimension set 4 (p. 960)

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnections	The current number of database connections in a transaction. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 960) , Dimension set 3 (p. 960) , Dimension set 4 (p. 960)
DatabaseConnections	The current session of database connections currently pinned because of operations in client requests that change session state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 960) , Dimension set 3 (p. 960) , Dimension set 4 (p. 960)
DatabaseConnections	The number of database connection requests that failed. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 3 (p. 960) , Dimension set 4 (p. 960)
DatabaseConnections	The number of database connections successfully established with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 3 (p. 960) , Dimension set 4 (p. 960)
DatabaseConnections	The current number of database connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 960) , Dimension set 3 (p. 960) , Dimension set 4 (p. 960)
MaxDatabaseConnections	The allowed number of database connections allowed. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 960) , Dimension set 3 (p. 960) , Dimension set 4 (p. 960)

Metric	Description	Valid period	CloudWatch dimension set
QueryDatabaseResponseLatency	The time in microseconds that the database took to respond to the query. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 2 (p. 960) , Dimension set 3 (p. 960) , Dimension set 4 (p. 960)
QueryRequests	The number of queries received. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 2 (p. 960)
QueryRequestsNoTLS	The number of queries received from non-TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 2 (p. 960)
QueryRequestsTLS	The number of queries received from TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 2 (p. 960)
QueryResponseLatency	The time in microseconds between getting a query request and the proxy responding to it. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1 (p. 960) , Dimension set 2 (p. 960)

You can find logs of RDS Proxy activity under CloudWatch in the AWS Management Console. Each proxy has an entry in the [Log groups](#) page.

Important

These logs are intended for human consumption for troubleshooting purposes and not for programmatic access. The format and content of the logs is subject to change.

In particular, older logs don't contain any prefixes indicating the endpoint for each request. In newer logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint, or the special name default for requests using the default endpoint of a proxy.

Working with RDS Proxy events

An *event* indicates a change in an environment. This can be an AWS environment or a service or application from a software as a service (SaaS) partner. Or it can be one of your own custom applications or services. For example, Amazon RDS generates an event when you create or modify an RDS Proxy. Amazon RDS delivers events to CloudWatch Events and Amazon EventBridge in near-real time. Following, you can find a list of RDS Proxy events that you can subscribe to and an example of an RDS Proxy event.

For more information about working with events, see the following:

- For instructions on how to view events by using the AWS Management Console, AWS CLI, or RDS API, see [Viewing Amazon RDS events \(p. 647\)](#).
- To learn how to configure Amazon RDS to send events to EventBridge, see [Creating a rule that triggers on an Amazon RDS event \(p. 664\)](#).

RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

Category	RDS event ID	Description
configuration change	RDS-EVENT-0204	RDS modified the DB proxy (RDS Proxy).
configuration change	RDS-EVENT-0207	RDS modified the endpoint of the DB proxy (RDS Proxy).
configuration change	RDS-EVENT-0213	RDS detected the addition of the DB instance and automatically added it to the target group of the DB proxy (RDS Proxy).
configuration change	RDS-EVENT-0214	RDS detected the deletion of the DB instance and automatically removed it from the target group of the DB proxy (RDS Proxy).
configuration change	RDS-EVENT-0215	RDS detected the deletion of the DB cluster and automatically removed it from the target group of the DB proxy (RDS Proxy).
creation	RDS-EVENT-0203	RDS created the DB proxy (RDS Proxy).
creation	RDS-EVENT-0206	RDS created the endpoint for the DB proxy (RDS Proxy).
deletion	RDS-EVENT-0205	RDS deleted the DB proxy (RDS Proxy).
deletion	RDS-EVENT-0208	RDS deleted the endpoint of DB proxy (RDS Proxy).
failure	RDS-EVENT-0243	RDS couldn't provision capacity for the proxy because there aren't enough IP addresses available in your subnets. To fix the issue, make sure that your subnets have the minimum number of unused IP addresses. To determine the recommended number for your instance class, see Planning for IP address capacity (p. 930) .

The following is an example of an RDS Proxy event in JSON format. The event shows that RDS modified the endpoint named `my-endpoint` of the RDS Proxy named `my-rds-proxy`. The event ID is `RDS-EVENT-0207`.

RDS Proxy command-line examples

To see how combinations of connection commands and SQL statements interact with RDS Proxy, look at the following examples.

Examples

- [Preserving Connections to a MySQL Database Across a Failover](#)
- [Adjusting the max_connections Setting for an Aurora DB Cluster](#)

Example Preserving connections to a MySQL database across a failover

This MySQL example demonstrates how open connections continue working during a failover. An example is when you reboot a database or it becomes unavailable due to a problem. This example uses a proxy named `the-proxy` and an Aurora DB cluster with DB instances `instance-8898` and `instance-9814`. When you run the `failover-db-cluster` command from the Linux command line, the writer instance that the proxy is connected to changes to a different DB instance. You can see that the DB instance associated with the proxy changes while the connection remains open.

```
$ mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p  
Enter password:  
...  
  
mysql> select @@aurora_server_id;  
+-----+  
| @@aurora_server_id |  
+-----+  
| instance-9814 |  
+-----+
```

```

1 row in set (0.01 sec)

mysql>
[1]+ Stopped                  mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -
u admin_user -p
$ # Initially, instance-9814 is the writer.
$ aws rds failover-db-cluster --db-cluster-identifier cluster-56-2019-11-14-1399
JSON output
$ # After a short time, the console shows that the failover operation is complete.
$ # Now instance-8898 is the writer.
$ fg
mysql -h the-proxy.proxy-demo.us.us-east-1.rds.amazonaws.com -u admin_user -p

mysql> select @@aurora_server_id;

```

Example Adjusting the max_connections setting for an Aurora DB cluster

This example demonstrates how you can adjust the max_connections setting for an Aurora MySQL DB cluster. To do so, you create your own DB cluster parameter group based on the default parameter settings for clusters that are compatible with MySQL 5.6 or 5.7. You specify a value for the max_connections setting, overriding the formula that sets the default value. You associate the DB cluster parameter group with your DB cluster.

```

export REGION=us-east-1
export CLUSTER_PARAM_GROUP=rds-proxy-mysql-56-max-connections-demo
export CLUSTER_NAME=rds-proxy-mysql-56

aws rds create-db-parameter-group --region $REGION \
    --db-parameter-group-family aurora5.6 \
    --db-parameter-group-name $CLUSTER_PARAM_GROUP \
    --description "Aurora MySQL 5.6 cluster parameter group for RDS Proxy demo."

aws rds modify-db-cluster --region $REGION \
    --db-cluster-identifier $CLUSTER_NAME \

```

```
--db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP

echo "New cluster param group is assigned to cluster:"
aws rds describe-db-clusters --region $REGION \
--db-cluster-identifier $CLUSTER_NAME \
--query '*[*].{DBClusterParameterGroup:DBClusterParameterGroup}'

echo "Current value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
--db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
--query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
--output text | grep "max_connections"

echo -n "Enter number for max_connections setting: "
read answer

aws rds modify-db-cluster-parameter-group --region $REGION --db-cluster-parameter-group-
name $CLUSTER_PARAM_GROUP \
--parameters "ParameterName=max_connections,ParameterValue=$
$answer,ApplyMethod=immediate"

echo "Updated value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
--db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
--query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
--output text | grep "max_connections"
```

Troubleshooting for RDS Proxy

Following, you can find troubleshooting ideas for some common RDS Proxy issues and information on CloudWatch logs for RDS Proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint. Or it can be the special name default for read/write requests using the default endpoint of a proxy. For more information about proxy endpoints, see [Working with Amazon RDS Proxy endpoints \(p. 952\)](#).

Topics

- [Verifying connectivity for a proxy \(p. 967\)](#)
- [Common issues and solutions \(p. 968\)](#)

Verifying connectivity for a proxy

You can use the following commands to verify that all components of the connection mechanism can communicate with the other components.

Examine the proxy itself using the [describe-db-proxies](#) command. Also examine the associated target group using the [describe-db-proxy-target-groups](#) command. Check that the details of the targets match the RDS DB instance or Aurora DB cluster that you intend to associate with the proxy. Use commands such as the following.

```
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
aws rds describe-db-proxy-target-groups --db-proxy-name $DB_PROXY_NAME
```

To confirm that the proxy can connect to the underlying database, examine the targets specified in the target groups using the [describe-db-proxy-targets](#) command. Use a command such as the following.

```
aws rds describe-db-proxy-targets --db-proxy-name $DB_PROXY_NAME
```

The output of the [describe-db-proxy-targets](#) command includes a TargetHealth field. You can examine the fields State, Reason, and Description inside TargetHealth to check if the proxy can communicate with the underlying DB instance.

- A State value of AVAILABLE indicates that the proxy can connect to the DB instance.
- A State value of UNAVAILABLE indicates a temporary or permanent connection problem. In this case, examine the Reason and Description fields. For example, if Reason has a value of PENDING_PROXY_CAPACITY, try connecting again after the proxy finishes its scaling operation. If Reason has a value of UNREACHABLE, CONNECTION_FAILED, or AUTH_FAILURE, use the explanation from the Description field to help you diagnose the issue.
- The State field might have a value of REGISTERING for a brief time before changing to AVAILABLE or UNAVAILABLE.

If the following Netcat command (nc) is successful, you can access the proxy endpoint from the EC2 instance or other system where you're logged in. This command reports failure if you're not in the same VPC as the proxy and the associated database. You might be able to log directly in to the database without being in the same VPC. However, you can't log into the proxy unless you're in the same VPC.

```
nc -zx MySQL_proxy_endpoint 3306  
nc -zx PostgreSQL_proxy_endpoint 5432
```

You can use the following commands to make sure that your EC2 instance has the required properties. In particular, the VPC for the EC2 instance must be the same as the VPC for the RDS DB instance or Aurora DB cluster that the proxy connects to.

```
aws ec2 describe-instances --instance-ids your_ec2_instance_id
```

Examine the Secrets Manager secrets used for the proxy.

```
aws secretsmanager list-secrets  
aws secretsmanager get-secret-value --secret-id your_secret_id
```

Make sure that the SecretString field displayed by get-secret-value is encoded as a JSON string that includes username and password fields. The following example shows the format of the SecretString field.

```
{  
    "ARN": "some_arn",  
    "Name": "some_name",  
    "VersionId": "some_version_id",  
    "SecretString": '{"username":"some_username","password":"some_password"}',  
    "VersionStages": [ "some_stage" ],  
    "CreatedDate": "some_timestamp"  
}
```

Common issues and solutions

For possible causes and solutions to some common problems that you might encounter using RDS Proxy, see the following.

You might encounter the following issues while creating a new proxy or connecting to a proxy.

Error	Causes or workarounds
403: The security token included in the request is invalid	Select an existing IAM role instead of choosing to create a new one.

You might encounter the following issues while connecting to a MySQL proxy.

Error	Causes or workarounds
ERROR 1040 (HY000): Connections rate limit exceeded (<i>limit_value</i>)	The rate of connection requests from the client to the proxy has exceeded the limit.
ERROR 1040 (HY000): IAM authentication rate limit exceeded	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.
ERROR 1040 (HY000): Number simultaneous connections exceeded (<i>limit_value</i>)	The number of simultaneous connection requests from the client to the proxy exceeded the limit.
ERROR 1045 (28000): Access denied for user ' <i>DB_USER</i> '@'%' (using password: YES)	Some possible reasons include the following: <ul style="list-style-type: none"> The Secrets Manager secret used by the proxy doesn't match the user name and password of an existing database user. Either update the credentials in the Secrets Manager secret, or make sure the database user exists and has the same password as in the secret.
ERROR 1105 (HY000): Unknown error	An unknown error occurred.
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of <i>value</i>	The value set for the character_set_client parameter is not valid. For example, the value ucs2 is not valid because it can crash the MySQL server.
ERROR 3159 (HY000): This RDS Proxy requires TLS connections.	You enabled the setting Require Transport Layer Security in the proxy but your connection included the parameter ssl-mode=DISABLED in the MySQL client. Do either of the following: <ul style="list-style-type: none"> Disable the setting Require Transport Layer Security for the proxy. Connect to the database using the minimum setting of ssl-mode=REQUIRED in the MySQL client.

Error	Causes or workarounds
ERROR 2026 (HY000): SSL connection error: Internal Server Error	<p>The TLS handshake to the proxy failed. Some possible reasons include the following:</p> <ul style="list-style-type: none"> SSL is required but the server doesn't support it. An internal server error occurred. A bad handshake occurred.
ERROR 9501 (HY000): Timed-out waiting to acquire database connection	<p>The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following:</p> <ul style="list-style-type: none"> The proxy is unable to establish a database connection because the maximum connections have been reached The proxy is unable to establish a database connection because the database is unavailable.

You might encounter the following issues while connecting to a PostgreSQL proxy.

Error	Cause	Solution
IAM authentication is allowed only with SSL connections.	The user tried to connect to the database using IAM authentication with the setting <code>sslmode=disable</code> in the PostgreSQL client.	The user needs to connect to the database using the minimum setting of <code>sslmode=require</code> in the PostgreSQL client. For more information, see the PostgreSQL SSL support documentation.
This RDS Proxy requires TLS connections.	The user enabled the option Require Transport Layer Security but tried to connect with <code>sslmode=disable</code> in the PostgreSQL client.	To fix this error, do one of the following: <ul style="list-style-type: none"> Disable the proxy's Require Transport Layer Security option. Connect to the database using the minimum setting of <code>sslmode=allow</code> in the PostgreSQL client.
IAM authentication failed for user <code>user_name</code> . Check the IAM token for this user and try again.	<p>This error might be due to the following reasons:</p> <ul style="list-style-type: none"> The client supplied the incorrect IAM user name. The client supplied an incorrect IAM authorization token for the user. The client is using an IAM policy that does not have the necessary permissions. The client supplied an expired IAM authorization token for the user. 	To fix this error, do the following: <ol style="list-style-type: none"> Confirm that the provided IAM user exists. Confirm that the IAM authorization token belongs to the provided IAM user. Confirm that the IAM policy has adequate permissions for RDS. Check the validity of the IAM authorization token used.

Error	Cause	Solution
This RDS proxy has no credentials for the role <i>role_name</i> . Check the credentials for this role and try again.	There is no Secrets Manager secret for this role.	Add a Secrets Manager secret for this role.
RDS supports only IAM or MD5 authentication.	The database client being used to connect to the proxy is using an authentication mechanism not currently supported by the proxy, such as SCRAM-SHA-256.	If you're not using IAM authentication, use the MD5 password authentication only.
A user name is missing from the connection startup packet. Provide a user name for this connection.	The database client being used to connect to the proxy isn't sending a user name when trying to establish a connection.	Make sure to define a user name when setting up a connection to the proxy using the PostgreSQL client of your choice.
Feature not supported: RDS Proxy supports only version 3.0 of the PostgreSQL messaging protocol.	The PostgreSQL client used to connect to the proxy uses a protocol older than 3.0.	Use a newer PostgreSQL client that supports the 3.0 messaging protocol. If you're using the PostgreSQL psql CLI, use a version greater than or equal to 7.4.
Feature not supported: RDS Proxy currently doesn't support streaming replication mode.	The PostgreSQL client used to connect to the proxy is trying to use the streaming replication mode, which isn't currently supported by RDS Proxy.	Turn off the streaming replication mode in the PostgreSQL client being used to connect.
Feature not supported: RDS Proxy currently doesn't support the option <i>option_name</i> .	Through the startup message, the PostgreSQL client used to connect to the proxy is requesting an option that isn't currently supported by RDS Proxy.	Turn off the option being shown as not supported from the message above in the PostgreSQL client being used to connect.
The IAM authentication failed because of too many competing requests.	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.	Reduce the rate in which connections using IAM authentication from a PostgreSQL client are established.
The maximum number of client connections to the proxy exceeded <i>number_value</i> .	The number of simultaneous connection requests from the client to the proxy exceeded the limit.	Reduce the number of active connections from PostgreSQL clients to this RDS proxy.
Rate of connection to proxy exceeded <i>number_value</i> .	The rate of connection requests from the client to the proxy has exceeded the limit.	Reduce the rate in which connections from a PostgreSQL client are established.

Error	Cause	Solution
The password that was provided for the role <i>role_name</i> is wrong.	The password for this role doesn't match the Secrets Manager secret.	Check the secret for this role in Secrets Manager to see if the password is the same as what's being used in your PostgreSQL client.
The IAM authentication failed for the role <i>role_name</i> . Check the IAM token for this role and try again.	There is a problem with the IAM token used for IAM authentication.	Generate a new authentication token and use it in a new connection.
IAM is allowed only with SSL connections.	A client tried to connect using IAM authentication, but SSL wasn't enabled.	Enable SSL in the PostgreSQL client.
Unknown error.	An unknown error occurred.	Reach out to AWS Support to investigate the issue.
Timed-out waiting to acquire database connection.	<p>The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following:</p> <ul style="list-style-type: none"> The proxy can't establish a database connection because the maximum connections have been reached. The proxy can't establish a database connection because the database is unavailable. 	<p>Possible solutions are the following:</p> <ul style="list-style-type: none"> Check the target of the RDS DB instance or Aurora DB cluster status to see if it's unavailable. Check if there are long-running transactions and/or queries being executed. They can use database connections from the connection pool for a long time.
Request returned an error: <i>database_error</i> .	The database connection established from the proxy returned an error.	The solution depends on the specific database error. One example is: Request returned an error: database "your-database-name" does not exist. This means that the specified database name doesn't exist on the database server. Or it means that the user name used as a database name (if a database name isn't specified) doesn't exist on the server.

Using RDS Proxy with AWS CloudFormation

You can use RDS Proxy with AWS CloudFormation. Doing so helps you to create groups of related resources. Such a group can include a proxy that can connect to a newly created Amazon RDS DB instance or Aurora DB cluster. RDS Proxy support in AWS CloudFormation involves two new registry types: `DBProxy` and `DBProxyTargetGroup`.

The following listing shows a sample AWS CloudFormation template for RDS Proxy.

```
Resources:
  DBProxy:
    Type: AWS::RDS::DBProxy
    Properties:
      DBProxyName: CanaryProxy
      EngineFamily: MYSQL
      RoleArn:
        Fn::ImportValue: SecretReaderRoleArn
      Auth:
        - {AuthScheme: SECRETS, SecretArn: !ImportValue ProxySecret, IAMAuth: DISABLED}
      VpcSubnetIds:
        Fn::Split: [",", "Fn::ImportValue": SubnetIds]

  ProxyTargetGroup:
    Type: AWS::RDS::DBProxyTargetGroup
    Properties:
      DBProxyName: CanaryProxy
      TargetGroupName: default
      DBInstanceIdentifiers:
        - Fn::ImportValue: DBInstanceName
    DependsOn: DBProxy
```

For more information about the Amazon RDS and Aurora resources that you can create using AWS CloudFormation, see [RDS resource type reference](#).

Amazon RDS for MariaDB

Amazon RDS supports DB instances that run the following versions of MariaDB:

- MariaDB 10.6
- MariaDB 10.5
- MariaDB 10.4
- MariaDB 10.3
- MariaDB 10.2 (end of life scheduled for October 15, 2022)

For more information about minor version support, see [MariaDB on Amazon RDS versions \(p. 982\)](#).

To create a MariaDB DB instance, use the Amazon RDS management tools or interfaces. You can then use the Amazon RDS tools to perform management actions for the DB instance. These include actions such as the following:

- Reconfiguring or resizing the DB instance
- Authorizing connections to the DB instance
- Creating and restoring from backups or snapshots
- Creating Multi-AZ secondaries
- Creating read replicas
- Monitoring the performance of your DB instance

To store and access the data in your DB instance, use standard MariaDB utilities and applications.

MariaDB is available in all of the AWS Regions. For more information about AWS Regions, see [Regions, Availability Zones, and Local Zones \(p. 72\)](#).

You can use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see [HIPAA compliance](#). AWS Services in Scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see [AWS services in scope by compliance program](#).

Before creating a DB instance, complete the steps in [Setting up for Amazon RDS \(p. 148\)](#). When you create a DB instance, the RDS master user gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running MariaDB inside a virtual private cloud (VPC) based on Amazon VPC. You can also add features to your MariaDB DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for MariaDB as a high-availability, failover solution.

Important

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as the mysql client. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

MariaDB feature support on Amazon RDS

RDS for MariaDB supports most of the features and capabilities of MariaDB. Some features might have limited support or restricted privileges.

You can filter new Amazon RDS features on the [What's New with Database?](#) page. For **Products**, choose **Amazon RDS**. Then search using keywords such as **MariaDB 2022**.

Note

The following lists are not exhaustive.

Topics

- [MariaDB feature support on Amazon RDS for MariaDB major versions \(p. 975\)](#)
- [Supported storage engines for MariaDB on Amazon RDS \(p. 979\)](#)
- [Cache warming for MariaDB on Amazon RDS \(p. 980\)](#)
- [MariaDB features not supported by Amazon RDS \(p. 981\)](#)

MariaDB feature support on Amazon RDS for MariaDB major versions

In the following sections, find information about MariaDB feature support on Amazon RDS for MariaDB major versions:

Topics

- [MariaDB 10.6 support on Amazon RDS \(p. 976\)](#)
- [MariaDB 10.5 support on Amazon RDS \(p. 977\)](#)
- [MariaDB 10.4 support on Amazon RDS \(p. 977\)](#)
- [MariaDB 10.3 support on Amazon RDS \(p. 978\)](#)

- [MariaDB 10.2 support on Amazon RDS \(p. 978\)](#)

For information about supported minor versions of Amazon RDS for MariaDB, see [MariaDB on Amazon RDS versions \(p. 982\)](#).

MariaDB 10.6 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.6 or higher:

- **MyRocks storage engine** – You can use the MyRocks storage engine with RDS for MariaDB to optimize storage consumption of your write-intensive, high-performance web applications. For more information, see [Supported storage engines for MariaDB on Amazon RDS \(p. 979\)](#) and [MyRocks](#).
- **AWS Identity and Access Management (IAM) DB authentication** – You can use IAM DB authentication for better security and central management of connections to your MariaDB DB instances. For more information, see [IAM database authentication for MariaDB, MySQL, and PostgreSQL \(p. 2048\)](#).
- **Upgrade options** – You can now upgrade to RDS for MariaDB version 10.6 from any prior major release (10.2, 10.3, 10.4, 10.5). You can also restore a snapshot of an existing MySQL 5.6 or 5.7 DB instance to a MariaDB 10.6 instance. For more information, see [Upgrading the MariaDB DB engine \(p. 998\)](#).
- **Delayed replication** – You can now set a configurable time period for which a read replica lags behind the source database. In a standard MariaDB replication configuration, there is minimal replication delay between the source and the replica. With delayed replication, you can set an intentional delay as a strategy for disaster recovery. For more information, see [Configuring delayed replication with MariaDB \(p. 1030\)](#).
- **Oracle PL/SQL compatibility** – By using RDS for MariaDB version 10.6, you can more easily migrate your legacy Oracle applications to Amazon RDS. For more information, see [SQL_MODE=ORACLE](#).
- **Atomic DDL** – Your dynamic data language (DDL) statements can be relatively crash-safe with RDS for MariaDB version 10.6. CREATE TABLE, ALTER TABLE, RENAME TABLE, DROP TABLE, DROP DATABASE and related DDL statements are now atomic. Either the statement succeeds, or it's completely reversed. For more information, see [Atomic DDL](#).
- **Other enhancements** – These enhancements include a JSON_TABLE function for transforming JSON data to relational format within SQL, and faster empty table data load with Innodb. They also include new sys_schema for analysis and troubleshooting, optimizer enhancement for ignoring unused indexes, and performance improvements. For more information, see [JSON_TABLE](#).
- **New default values for parameters** – The following parameters have new default values for MariaDB version 10.6 DB instances:
 - The default value for the following parameters has changed from utf8 to utf8mb3:
 - [character_set_client](#)
 - [character_set_connection](#)
 - [character_set_results](#)
 - [character_set_system](#)

Although the default values have changed for these parameters, there is no functional change. For more information, see [Supported Character Sets and Collations](#) in the MariaDB documentation.

- The default value of the [collation_connection](#) parameter has changed from utf8_general_ci to utf8mb3_general_ci. Although the default value has changed for this parameter, there is no functional change.
- The default value of the [old_mode](#) parameter has changed from unset to UTF8_IS_UTF8MB3. Although the default value has changed for this parameter, there is no functional change.

For a list of all MariaDB 10.6 features and their documentation, see [Changes and improvements in MariaDB 10.6](#) and [Release notes - MariaDB 10.6 series](#) on the MariaDB website.

For a list of unsupported features, see [MariaDB features not supported by Amazon RDS \(p. 981\)](#).

MariaDB 10.5 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.5 or later:

- **InnoDB enhancements** – MariaDB version 10.5 includes InnoDB enhancements. For more information, see [InnoDB: Performance Improvements etc.](#) in the MariaDB documentation.
- **Performance schema updates** – MariaDB version 10.5 includes performance schema updates. For more information, see [Performance Schema Updates to Match MySQL 5.7 Instrumentation and Tables](#) in the MariaDB documentation.
- **One file in the InnoDB redo log** – In versions of MariaDB before version 10.5, the value of the `innodb_log_files_in_group` parameter was set to 2. In MariaDB version 10.5, the value of this parameter is set to 1.

If you are upgrading from a prior version to MariaDB version 10.5, and you don't modify the parameters, the `innodb_log_file_size` parameter value is unchanged. However, it applies to one log file instead of two. The result is that your upgraded MariaDB version 10.5 DB instance uses half of the redo log size that it was using before the upgrade. This change can have a noticeable performance impact. To address this issue, you can double the value of the `innodb_log_file_size` parameter. For information about modifying parameters, see [Modifying parameters in a DB parameter group \(p. 294\)](#).

- **SHOW SLAVE STATUS command not supported** – In versions of MariaDB before version 10.5, the `SHOW SLAVE STATUS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5, the equivalent `SHOW REPLICA STATUS` command requires the `REPLICATION REPLICA ADMIN` privilege. This new privilege isn't granted to the RDS master user.

Instead of using the `SHOW REPLICA STATUS` command, run the new `mysql.rds_replica_status` stored procedure to return similar information. For more information, see [mysql.rds_replica_status \(p. 1049\)](#).

- **SHOW RELAYLOG EVENTS command not supported** – In versions of MariaDB before version 10.5, the `SHOW RELAYLOG EVENTS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5, this command requires the `REPLICATION REPLICA ADMIN` privilege. This new privilege isn't granted to the RDS master user.
- **New default values for parameters** – The following parameters have new default values for MariaDB version 10.5 DB instances:
 - The default value of the `max_connections` parameter has changed to `LEAST({DBInstanceClassMemory/25165760}, 12000)`. For information about the `LEAST` parameter function, see [DB parameter functions \(p. 312\)](#).
 - The default value of the `innodb_adaptive_hash_index` parameter has changed to `OFF (0)`.
 - The default value of the `innodb_checksum_algorithm` parameter has changed to `full_crc32`.
 - The default value of the `innodb_log_file_size` parameter has changed to 2 GB.

For a list of all MariaDB 10.5 features and their documentation, see [Changes and improvements in MariaDB 10.5](#) and [Release notes - MariaDB 10.5 series](#) on the MariaDB website.

For a list of unsupported features, see [MariaDB features not supported by Amazon RDS \(p. 981\)](#).

MariaDB 10.4 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.4 or later:

- **User account security enhancements** – Password expiration and [account locking improvements](#)

- **Optimizer enhancements** – Optimizer trace feature
- **InnoDB enhancements** – Instant DROP COLUMN support and instant VARCHAR extension for ROW_FORMAT=DYNAMIC and ROW_FORMAT=COMPACT
- **New parameters** – Including `tcp_nodedelay`, `tls_version`, and `gtid_cleanup_batch_size`

For a list of all MariaDB 10.4 features and their documentation, see [Changes and improvements in MariaDB 10.4](#) and [Release notes - MariaDB 10.4 series](#) on the MariaDB website.

For a list of unsupported features, see [MariaDB features not supported by Amazon RDS \(p. 981\)](#).

MariaDB 10.3 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.3 or later:

- **Oracle compatibility** – PL/SQL compatibility parser, sequences, INTERSECT and EXCEPT to complement UNION, new TYPE OF and ROW TYPE OF declarations, and invisible columns
- **Temporal data processing** – System versioned tables for querying of past and present states of the database
- **Flexibility** – User-defined aggregates, storage-independent column compression, and proxy protocol support to relay the client IP address to the server
- **Manageability** – Instant ADD COLUMN operations and fast-fail data definition language (DDL) operations

For a list of all MariaDB 10.3 features and their documentation, see [Changes & improvements in MariaDB 10.3](#) and [Release notes - MariaDB 10.3 series](#) on the MariaDB website.

For a list of unsupported features, see [MariaDB features not supported by Amazon RDS \(p. 981\)](#).

MariaDB 10.2 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.2 or later:

- ALTER USER
- Common Table Expressions
- Compressing Events to Reduce Size of the Binary Log
- CREATE USER — new options for limiting resource usage and SSL/TLS
- EXECUTE IMMEDIATE
- Flashback
- InnoDB — now the default storage engine instead of XtraDB
- InnoDB — set the buffer pool size dynamically
- JSON Functions
- Window Functions
- WITH

For a list of all MariaDB 10.2 features and their documentation, see [Changes & improvements in MariaDB 10.2](#) and [Release notes - MariaDB 10.2 series](#) on the MariaDB website.

For a list of unsupported features, see [MariaDB features not supported by Amazon RDS \(p. 981\)](#).

Supported storage engines for MariaDB on Amazon RDS

RDS for MariaDB supports the following storage engines.

Topics

- [The InnoDB storage engine \(p. 979\)](#)
- [The MyRocks storage engine \(p. 979\)](#)

Other storage engines aren't currently supported by RDS for MariaDB.

The InnoDB storage engine

Although MariaDB supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. InnoDB is the recommended storage engine for MariaDB DB instances on Amazon RDS. Amazon RDS features such as point-in-time restore and snapshot restore require a recoverable storage engine and are supported only for the recommended storage engine for the MariaDB version.

For more information, see [InnoDB](#).

The MyRocks storage engine

The MyRocks storage engine is available in RDS for MariaDB version 10.6 and higher. Before using the MyRocks storage engine in a production database, we recommend that you perform thorough benchmarking and testing to verify any potential benefits over InnoDB for your use case.

The default parameter group for MariaDB version 10.6 includes MyRocks parameters. For more information, see [Parameters for MariaDB \(p. 1043\)](#) and [Working with parameter groups \(p. 289\)](#).

To create a table that uses the MyRocks storage engine, specify ENGINE= RocksDB in the CREATE TABLE statement. The following example creates a table that uses the MyRocks storage engine.

```
CREATE TABLE test (a INT NOT NULL, b CHAR(10)) ENGINE=RocksDB;
```

We strongly recommend that you don't run transactions that span both InnoDB and MyRocks tables. MariaDB doesn't guarantee ACID (atomicity, consistency, isolation, durability) for transactions across storage engines. Although it is possible to have both InnoDB and MyRocks tables in a DB instance, we don't recommend this approach except during a migration from one storage engine to the other. When both InnoDB and MyRocks tables exist in a DB instance, each storage engine has its own buffer pool, which might cause performance to degrade.

MyRocks doesn't support SERIALIZABLE isolation or gap locks. So, generally you can't use MyRocks with statement-based replication. For more information, see [MyRocks and Replication](#).

Currently, you can modify only the following MyRocks parameters:

- [rocksdb_block_cache_size](#)
- [rocksdb_bulk_load](#)
- [rocksdb_bulk_load_size](#)
- [rocksdb_deadlock_detect](#)
- [rocksdb_deadlock_detect_depth](#)

- [rocksdb_max_latest_deadlocks](#)

The MyRocks storage engine and the InnoDB storage engine can compete for memory based on the settings for the `rocksdb_block_cache_size` and `innodb_buffer_pool_size` parameters. In some cases, you might only intend to use the MyRocks storage engine on a particular DB instance. If so, we recommend setting the `innodb_buffer_pool_size` minimal parameter to a minimal value and setting the `rocksdb_block_cache_size` as high as possible.

You can access MyRocks log files by using the [DescribeDBLogFiles](#) and [DownloadDBLogFilePortion](#) operations.

For more information about MyRocks, see [MyRocks](#) on the MariaDB website.

Cache warming for MariaDB on Amazon RDS

InnoDB cache warming can provide performance gains for your MariaDB DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This approach bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. For more information on cache warming, see [Dumping and restoring the buffer pool](#) in the MariaDB documentation.

Cache warming is enabled by default on MariaDB 10.2 and higher DB instances. To enable it, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group affects all MariaDB DB instances that use that parameter group. To enable cache warming for specific MariaDB DB instances, you might need to create a new parameter group for those DB instances. For information on parameter groups, see [Working with parameter groups \(p. 289\)](#).

Cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you don't commonly see a significant performance benefit.

Important

If your MariaDB DB instance doesn't shut down normally, such as during a failover, then the buffer pool state isn't saved to disk. In this case, MariaDB loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool before the restart. To ensure that you have a recent state of the buffer pool available to warm the cache on startup, we recommend that you periodically dump the buffer pool "on demand." You can dump or load the buffer pool on demand.

You can create an event to dump the buffer pool automatically and at a regular interval. For example, the following statement creates an event named `periodic_buffer_pool_dump` that dumps the buffer pool every hour.

```
CREATE EVENT periodic_buffer_pool_dump
  ON SCHEDULE EVERY 1 HOUR
  DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information, see [Events](#) in the MariaDB documentation.

Dumping and loading the buffer pool on demand

You can save and load the cache on demand using the following stored procedures:

- To dump the current state of the buffer pool to disk, call the [mysql.rds_innodb_buffer_pool_dump_now \(p. 1458\)](#) stored procedure.

- To load the saved state of the buffer pool from disk, call the [mysql.rds_innodb_buffer_pool_load_now \(p. 1458\)](#) stored procedure.
- To cancel a load operation in progress, call the [mysql.rds_innodb_buffer_pool_load_abort \(p. 1459\)](#) stored procedure.

MariaDB features not supported by Amazon RDS

The following MariaDB features are not supported on Amazon RDS:

- S3 storage engine
- Authentication plugin – GSSAPI
- Authentication plugin – Unix Socket
- AWS Key Management encryption plugin
- Delayed replication for MariaDB versions lower than 10.6
- Native MariaDB encryption at rest for InnoDB and Aria.

You can enable encryption at rest for a MariaDB DB instance by following the instructions in [Encrypting Amazon RDS resources \(p. 2000\)](#).

- HandlerSocket
- JSON table type for MariaDB versions lower than 10.6
- MariaDB ColumnStore
- MariaDB Galera Cluster
- Multisource replication
- MyRocks storage engine for MariaDB versions lower than 10.6
- Password validation plugin, `simple_password_check`, and `cracklib_password_check`
- Spider storage engine
- Sphinx storage engine
- TokuDB storage engine
- Storage engine-specific object attributes, as described in [Engine-defined new Table/Field/Index attributes](#) in the MariaDB documentation
- Table and tablespace encryption

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection.

MariaDB on Amazon RDS versions

For MariaDB, version numbers are organized as version X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes, for example going from version 10.5 to 10.6. A version change is considered minor if only the minor version number changes, for example going from version 10.6.5 to 10.6.7.

Topics

- [Supported MariaDB versions on Amazon RDS \(p. 982\)](#)
- [RDS for MariaDB release calendar \(p. 983\)](#)
- [MariaDB 10.3 end of life \(p. 984\)](#)
- [MariaDB 10.2 end of life \(p. 984\)](#)
- [Deprecated versions for Amazon RDS for MariaDB \(p. 985\)](#)

Supported MariaDB versions on Amazon RDS

Amazon RDS currently supports the following versions of MariaDB:

Major version	Minor version
MariaDB 10.6	<ul style="list-style-type: none">• 10.6.11• 10.6.10• 10.6.8• 10.6.7• 10.6.5
MariaDB 10.5	<ul style="list-style-type: none">• 10.5.18• 10.5.17• 10.5.16• 10.5.15• 10.5.13• 10.5.12
MariaDB 10.4	<ul style="list-style-type: none">• 10.4.27• 10.4.26• 10.4.25• 10.4.24
MariaDB 10.3	<ul style="list-style-type: none">• 10.3.37• 10.3.36• 10.3.35• 10.3.34

You can specify any currently supported MariaDB version when creating a new DB instance. You can specify the major version (such as MariaDB 10.5), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent

release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the [describe-db-engine-versions](#) AWS CLI command.

For example, to list the supported engine versions for RDS for MariaDB, run the following CLI command:

```
aws rds describe-db-engine-versions --engine mariadb --query "*[].{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

The default MariaDB version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

```
aws rds describe-db-engine-versions --default-only --engine mariadb --engine-version major-engine-version --region region --query "*[].{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

Replace *major-engine-version* with the major engine version, and replace *region* with the AWS Region. For example, the following AWS CLI command returns the default MariaDB minor engine version for the 10.5 major version and the US West (Oregon) AWS Region (us-west-2):

```
aws rds describe-db-engine-versions --default-only --engine mariadb --engine-version 10.5 --region us-west-2 --query "*[].{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

RDS for MariaDB release calendar

RDS for MariaDB major versions remain available at least until community end of life for the corresponding community version. You can use the following dates to plan your testing and upgrade cycles. If Amazon extends support for an RDS for MariaDB version for longer than originally stated, we plan to update this table to reflect the later date.

Note

Dates with only a month and a year are approximate and are updated with an exact date when it's known.

MariaDB major version	Community release date	RDS release date	Community end of life date	RDS end of standard support date
MariaDB 10.6 Current minor version: 10.6.11	6 July 2021	3 February 2022	6 July 2026	July 2026
MariaDB 10.5 Current minor version: 10.5.18	24 June 2020	21 January 2021	24 June 2025	June 2025
MariaDB 10.4 Current minor version: 10.4.27	18 June 2019	6 April 2020	18 June 2024	June 2024
MariaDB 10.3 Current minor version: 10.3.37	25 May 2018	23 October 2018	25 May 2023	23 October 2023

MariaDB major version	Community release date	RDS release date	Community end of life date	RDS end of standard support date
MariaDB 10.2	23 May 2017	5 Jan 2018	23 May 2022	15 Oct 2022
Current minor version: 10.2.44				

MariaDB 10.3 end of life

On October 23, 2023, Amazon RDS is starting the end-of-life process for MariaDB version 10.3 using the following schedule, which includes upgrade recommendations. The end-of-life process ends standard support for this version. We recommend that you upgrade all MariaDB 10.3 DB instances to MariaDB 10.6 as soon as possible. For more information, see [Upgrading the MariaDB DB engine \(p. 998\)](#).

Action or recommendation	Dates
We recommend that you manually upgrade MariaDB 10.3 DB instances to the version of your choice. You can upgrade directly to MariaDB version 10.6.	Now–October 23, 2023
We recommend that you manually upgrade MariaDB 10.3 snapshots to the version of your choice.	Now–October 23, 2023
You can no longer create new MariaDB 10.3 DB instances.	August 23, 2023
You can still create read replicas of existing MariaDB 10.3 DB instances and change them from Single-AZ deployments to Multi-AZ deployments.	
Amazon RDS starts automatic upgrades of your MariaDB 10.3 DB instances to version 10.6.	October 23, 2023
Amazon RDS starts automatic upgrades to version 10.6 for any MariaDB 10.3 DB instances restored from snapshots.	October 23, 2023
Amazon RDS automatically upgrades any remaining MariaDB 10.3 DB instances to version 10.6 whether or not they are in a scheduled maintenance window.	January 23, 2024

MariaDB 10.2 end of life

On October 15, 2022, Amazon RDS is starting the end-of-life process for MariaDB version 10.2 using the following schedule, which includes upgrade recommendations. The end-of-life process ends standard support for this version. We recommend that you upgrade all MariaDB 10.2 DB instances to MariaDB 10.3 or higher as soon as possible. For more information, see [Upgrading the MariaDB DB engine \(p. 998\)](#).

Action or recommendation	Dates
We recommend that you upgrade MariaDB 10.2 DB instances manually to the version of your choice. You can upgrade directly to MariaDB version 10.3 or 10.6.	Now–October 15, 2022
We recommend that you upgrade MariaDB 10.2 snapshots manually to the version of your choice.	Now–October 15, 2022
You can no longer create new MariaDB 10.2 DB instances. You can still create read replicas of existing MariaDB 10.2 DB instances and change them from Single-AZ deployments to Multi-AZ deployments.	July 15, 2022
Amazon RDS starts automatic upgrades of your MariaDB 10.2 DB instances to version 10.3.	October 15, 2022
Amazon RDS starts automatic upgrades to version 10.3 for any MariaDB 10.2 DB instances restored from snapshots.	October 15, 2022
Amazon RDS automatically upgrades any remaining MariaDB 10.2 DB instances to version 10.3 whether or not they are in a scheduled maintenance window.	January 15, 2023

For more information about Amazon RDS for MariaDB 10.2 end of life, see [Announcement: Amazon Relational Database Service \(Amazon RDS\) for MariaDB 10.2 End-of-Life date is October 15, 2022](#).

Deprecated versions for Amazon RDS for MariaDB

Amazon RDS for MariaDB version 10.0, 10.1, and 10.2 are deprecated.

For information about the Amazon RDS deprecation policy for MariaDB, see [Amazon RDS FAQs](#).

Connecting to a DB instance running the MariaDB database engine

After Amazon RDS provisions your DB instance, you can use any standard MariaDB client application or utility to connect to the instance. In the connection string, you specify the Domain Name System (DNS) address from the DB instance endpoint as the host parameter. You also specify the port number from the DB instance endpoint as the port parameter.

You can connect to an Amazon RDS for MariaDB DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see [mysql command-line client](#) in the MariaDB documentation. One GUI-based application that you can use to connect is Heidi. For more information, see the [Download HeidiSQL](#) page. For information about installing MySQL (including the MySQL command-line client), see [Installing and upgrading MySQL](#).

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on most RPM-based Linux distributions, including Amazon Linux 2, run the following command.

```
yum install mariadb
```

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command.

```
apt-get install mariadb-client
```

To check the version of your MySQL command-line client, run the following command.

```
mysql --version
```

To read the MySQL documentation for your current client version, run the following command.

```
man mysql
```

To connect to a DB instance from outside of a virtual private cloud (VPC) based on Amazon VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see [Can't connect to Amazon RDS DB instance \(p. 2141\)](#).

You can use SSL encryption on connections to a MariaDB DB instance. For information, see [Using SSL/TLS with a MariaDB DB instance \(p. 992\)](#).

Topics

- [Finding the connection information for a MariaDB DB instance \(p. 986\)](#)
- [Connecting from the MySQL command-line client \(unencrypted\) \(p. 989\)](#)
- [Troubleshooting connections to your MariaDB DB instance \(p. 990\)](#)

Finding the connection information for a MariaDB DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is mydb.123456789012.us-

`east-1.rds.amazonaws.com`. In this case, the port value is 3306, and the database user is admin. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify `mydb.123456789012.us-east-1.rds.amazonaws.com`.
- For port, specify 3306.
- For user, specify admin.

To connect to a DB instance, use any client for the MariaDB DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS Command Line Interface (AWS CLI) [describe-db-instances](#) command, or the Amazon RDS API [DescribeDBInstances](#) operation to list its details.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the MariaDB DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

The screenshot shows the AWS RDS console for a database named 'mydb'. The 'Summary' tab is selected, displaying basic information like DB identifier, Role, and Instance. The 'Connectivity & security' tab is active, showing the endpoint and port details. Two specific fields, 'Endpoint' and 'Port', are highlighted with red circles.

Summary

DB identifier	CPU
mydb	2.33%

Role: Instance

Current activity: 0 Connections

Connectivity & security

Endpoint & port	Network
Endpoint: mydb. [REDACTED].us-east-1.rds.amazonaws.com	Available
Port: 3306	VPC: vpc-6E [REDACTED]
	Subnet: default

5. If you need to find the master user name, choose the **Configuration** tab and view the **Master username** value.

AWS CLI

To find the connection information for a MariaDB DB instance by using the AWS CLI, call the [describe-db-instances](#) command. In the call, query for the DB instance ID, endpoint, port, and master user name.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
--filters "Name=engine,Values=mariadb" \
--query "[].{DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername}"
```

For Windows:

```
aws rds describe-db-instances ^
--filters "Name=engine,Values=mariadb" ^
--query "[].{DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername}"
```

Your output should be similar to the following.

```
[  
  [  
    "mydb1",  
    "mydb1.123456789012.us-east-1.rds.amazonaws.com",  
    3306,  
    "admin"  
  ],  
  [  
    "mydb2",  
    "mydb2.123456789012.us-east-1.rds.amazonaws.com",  
    3306,  
    "admin"  
  ]  
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the [DescribeDBInstances](#) operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Connecting from the MySQL command-line client (unencrypted)

Important

Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see [Connecting from the MySQL command-line client with SSL/TLS \(encrypted\) \(p. 993\)](#).

To connect to a DB instance using the MySQL command-line client, enter the following command at a command prompt on a client computer. Doing this connects you to a database on a MariaDB DB instance. Substitute the DNS name (endpoint) for your DB instance for `<endpoint>` and the master user name that you used for `<mymasteruser>`. Provide the master password that you used when prompted for a password.

```
mysql -h <endpoint> -P 3306 -u <mymasteruser> -p
```

After you enter the password for the user, you see output similar to the following.

```
Welcome to the MariaDB monitor. Commands end with ; or \g.  
Your MariaDB connection id is 31  
Server version: 10.5.15-MariaDB-log Source distribution
```

```
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.
```

```
Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.
```

```
MariaDB [(none)]>
```

Troubleshooting connections to your MariaDB DB instance

Two common causes of connection failures to a new DB instance are the following:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MariaDB application or utility is running. The DB instance must have a VPC security group that authorizes the connections. For more information, see [Amazon VPC VPCs and Amazon RDS \(p. 2103\)](#).

You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser.

- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see [Can't connect to Amazon RDS DB instance \(p. 2141\)](#).

Securing MariaDB DB instance connections

You can manage the security of your MariaDB DB instances.

Topics

- [MariaDB security on Amazon RDS \(p. 991\)](#)
- [Encrypting client connections to MariaDB DB instances with SSL/TLS \(p. 992\)](#)
- [Using new SSL/TLS certificates for MariaDB DB instances \(p. 994\)](#)

MariaDB security on Amazon RDS

Security for MariaDB DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see [Identity and access management for Amazon RDS \(p. 2016\)](#).
- When you create a DB instance, you use a VPC security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Socket Layer (SSL) and Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.
- Once a connection has been opened to a MariaDB DB instance, authentication of the login and permissions are applied the same way as in a stand-alone instance of MariaDB. Commands such as CREATE USER, RENAME USER, GRANT, REVOKE, and SET PASSWORD work just as they do in stand-alone databases, as does directly modifying database schema tables.

When you create an Amazon RDS DB instance, the master user has the following default privileges:

- alter
- alter routine
- create
- create routine
- create temporary tables
- create user
- create view
- delete
- drop
- event
- execute
- grant option
- index
- insert
- lock tables
- process
- references
- reload

This privilege is limited on MariaDB DB instances. It doesn't grant access to the FLUSH LOGS or FLUSH TABLES WITH READ LOCK operations.

- replication client
- replication slave
- select
- show databases
- show view
- trigger
- update

For more information about these privileges, see [User account management](#) in the MariaDB documentation.

Note

Although you can delete the master user on a DB instance, we don't recommend doing so. To recreate the master user, use the `ModifyDBInstance` API or the `modify-db-instance` AWS CLI and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the `rdsadmin` user is created when the DB instance is created. Attempting to drop, rename, change the password for, or change privileges for the `rdsadmin` account results in an error.

To allow management of the DB instance, the standard `kill` and `kill_query` commands have been restricted. The Amazon RDS commands `mysql.rds_kill`, `mysql.rds_kill_query`, and `mysql.rds_kill_query_id` are provided for use in MariaDB and also MySQL so that you can end user sessions or queries on DB instances.

Encrypting client connections to MariaDB DB instances with SSL/TLS

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS). Amazon RDS supports SSL/TLS encryption for MariaDB DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your MariaDB DB instance. SSL/TLS support is available in all AWS Regions.

Topics

- [Using SSL/TLS with a MariaDB DB instance \(p. 992\)](#)
- [Connecting from the MySQL command-line client with SSL/TLS \(encrypted\) \(p. 993\)](#)

Using SSL/TLS with a MariaDB DB instance

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

An SSL/TLS certificate created by Amazon RDS is the trusted root entity and should work in most cases but might fail if your application does not accept certificate chains. If your application does not accept certificate chains, you might need to use an intermediate certificate to connect to your AWS Region. For

example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions using SSL/TLS.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 2005\)](#). For more information about using SSL/TLS with MySQL, see [Using new SSL/TLS certificates for MariaDB DB instances \(p. 994\)](#).

Amazon RDS for MariaDB supports Transport Layer Security (TLS) versions 1.0, 1.1, 1.2, and 1.3 for all MariaDB versions.

You can require SSL/TLS connections for specific users accounts. For example, you can use one of the following statements, depending on your MariaDB version, to require SSL/TLS connections on the user account `encrypted_user`.

Use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL/TLS connections with MariaDB, see [Securing Connections for Client and Server](#) in the MariaDB documentation.

Connecting from the MySQL command-line client with SSL/TLS (encrypted)

The `mysql` client program parameters are slightly different if you are using the MySQL 5.7 version, the MySQL 8.0 version, or the MariaDB version.

To find out which version you have, run the `mysql` command with the `--version` option. In the following example, the output shows that the client program is from MariaDB.

```
$ mysql --version
mysql Ver 15.1 Distrib 10.5.15-MariaDB, for osx10.15 (x86_64) using readline 5.1
```

Most Linux distributions, such as Amazon Linux, CentOS, SUSE, and Debian have replaced MySQL with MariaDB, and the `mysql` version in them is from MariaDB.

To connect to your DB instance using SSL/TLS, follow these steps:

To connect to a DB instance with SSL/TLS using the MySQL command-line client

1. Download a root certificate that works for all AWS Regions.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 2005\)](#).

2. Use a MySQL command-line client to connect to a DB instance with SSL/TLS encryption. For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `--ssl-ca` parameter, substitute the SSL/TLS certificate file name. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

The following example shows how to launch the client using the `--ssl-ca` parameter using the MariaDB client:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-
bundle.pem --ssl -P 3306 -u myadmin -p
```

To require that the SSL/TLS connection verifies the DB instance endpoint against the endpoint in the SSL/TLS certificate, enter the following command:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-
bundle.pem --ssl-verify-server-cert -P 3306 -u myadmin -p
```

The following example shows how to launch the client using the `--ssl-ca` parameter using the MySQL 5.7 client or later:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-
bundle.pem --ssl-mode=REQUIRED -P 3306 -u myadmin -p
```

3. Enter the master user password when prompted.

You should see output similar to the following.

```
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 31
Server version: 10.5.15-MariaDB-log Source distribution

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

Using new SSL/TLS certificates for MariaDB DB instances

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether your applications require certificate verification to connect to your DB instances.

Note

Some applications are configured to connect to MariaDB only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

You can specify the following SSL modes: disabled, preferred, and required. When you use the preferred SSL mode and the CA certificate doesn't exist or isn't up to date, the connection falls back to not using SSL and still connects successfully.

We recommend avoiding preferred mode. In preferred mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate \(p. 2007\)](#). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 2005\)](#). For information about using SSL/TLS with MariaDB DB instances, see [Using SSL/TLS with a MariaDB DB instance \(p. 992\)](#).

Topics

- Determining whether a client requires certificate verification in order to connect (p. 995)
- Updating your application trust store (p. 996)
- Example Java code for establishing SSL connections (p. 996)

Determining whether a client requires certificate verification in order to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

JDBC

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see [Configuration properties](#) in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

Note

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

MySQL

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see [Client-side configuration for encrypted connections](#) in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --
ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --
ssl-verify-server-cert
```

Updating your application trust store

For information about updating the trust store for MySQL applications, see [Using TLS/SSL with MariaDB Connector/J](#) in the MariaDB documentation.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 2005\)](#).

For sample scripts that import certificates, see [Sample script for importing certificates into your trust store \(p. 2014\)](#).

Note

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the MariaDB Connector/J JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -
Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection using JDBC.

```
private static final String DB_USER = "admin";

private static final String DB_USER = "user name";
private static final String DB_PASSWORD = "password";
// This key store has only the prod root ca.
private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
private static final String KEY_STORE_PASS = "keystore-password";

public static void main(String[] args) throws Exception {
    Class.forName("org.mariadb.jdbc.Driver");

    System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
    System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

    Properties properties = new Properties();
    properties.put("user", DB_USER);
    properties.put("password", DB_PASSWORD);

    Connection connection = DriverManager.getConnection("jdbc:mysql://ssl-mariadb-
public.cni62e2e7kwh.us-east-1.rds.amazonaws.com:3306?useSSL=true", properties);
```

```
Statement stmt=connection.createStatement();
ResultSet rs=stmt.executeQuery("SELECT 1 from dual");
return;
}
```

Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance \(p. 2007\)](#).

Upgrading the MariaDB DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MariaDB DB instances: major version upgrades and minor version upgrades.

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the instructions in [Major version upgrades for MariaDB \(p. 999\)](#).

In contrast, *minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. For information about performing an upgrade, see [Upgrading a DB instance engine version \(p. 360\)](#).

If your MariaDB DB instance is using read replicas, you must upgrade all of the read replicas before upgrading the source instance. If your DB instance is in a Multi-AZ deployment, both the writer and standby replicas are upgraded. Your DB instance might not be available until the upgrade is complete.

For more information about MariaDB supported versions and version management, see [MariaDB on Amazon RDS versions \(p. 982\)](#).

Note

Database engine upgrades require downtime. The duration of the downtime varies based on the size of your DB instance.

Topics

- [Overview of upgrading \(p. 998\)](#)
- [Major version upgrades for MariaDB \(p. 999\)](#)
- [Upgrading a MariaDB DB instance \(p. 1000\)](#)
- [Automatic minor version upgrades for MariaDB \(p. 1000\)](#)

Overview of upgrading

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mariadb \
--engine-version version-number \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mariadb ^
--engine-version version-number ^
```

```
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --  
output text
```

For example, to identify the valid upgrade targets for a MariaDB version 10.5.15 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \  
--engine mariadb \  
--engine-version 10.5.15 \  
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --  
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^  
--engine mariadb ^  
--engine-version 10.5.15 ^  
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --  
output text
```

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. If the upgrade doesn't work for your databases, you can restore this snapshot to create a DB instance running the old version. The second DB snapshot is taken when the upgrade completes.

Note

Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see [Modifying an Amazon RDS DB instance \(p. 327\)](#).

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance is using read replication, you must upgrade all of the Read Replicas before upgrading the source instance.

If your DB instance is in a Multi-AZ deployment, both the primary and standby DB instances are upgraded. The primary and standby DB instances are upgraded at the same time and you will experience an outage until the upgrade is complete. The time for the outage varies based on your database engine, engine version, and the size of your DB instance.

Major version upgrades for MariaDB

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically. You must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

Amazon RDS supports the following in-place upgrades for major versions of the MariaDB database engine:

- Any MariaDB version to MariaDB 10.6

- MariaDB 10.4 to MariaDB 10.5
- MariaDB 10.3 to MariaDB 10.4
- MariaDB 10.2 to MariaDB 10.3

To perform a major version upgrade to MariaDB version 10.6, you can upgrade directly from any MariaDB version to version 10.6.

To perform a major version upgrade to a MariaDB version lower than 10.6, upgrade to each major version in order. For example, to upgrade from version 10.2 to version 10.5, upgrade in the following order: 10.2 to 10.3, 10.3 to 10.4, and then 10.4 to 10.5.

If you are using a custom parameter group, and you perform a major version upgrade, you must specify either a default parameter group for the new DB engine version or create your own custom parameter group for the new DB engine version. Associating the new parameter group with the DB instance requires a customer-initiated database reboot after the upgrade completes. The instance's parameter group status will show pending-reboot if the instance needs to be rebooted to apply the parameter group changes. An instance's parameter group status can be viewed in the AWS console or by using a "describe" call such as `describe-db-instances`.

Upgrading a MariaDB DB instance

For information about manually or automatically upgrading a MariaDB DB instance, see [Upgrading a DB instance engine version \(p. 360\)](#).

Automatic minor version upgrades for MariaDB

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.

In the AWS Management Console, these settings are under **Additional configuration**. The following image shows the **Auto minor version upgrade** setting.

Maintenance

Auto minor version upgrade [Info](#)

Enable auto minor version upgrade
Enabling auto minor version upgrade will automatically upgrade to new minor versions as they are released. The automatic upgrades occur during the maintenance window for the database.

Maintenance window [Info](#)
Select the period you want pending modifications or maintenance applied to the database by Amazon RDS.

Select window
 No preference

Start day	Start time	Duration
Monday ▾	00 ▾ : 00 ▾ UTC	0.5 ▾ hours

For more information about these settings, see [Settings for DB instances \(p. 328\)](#).

For some RDS for MariaDB major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MariaDB community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MariaDB minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mariadb \
--engine-version minor-version \
--region region \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mariadb ^
--engine-version minor-version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MariaDB minor version 10.2.39 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mariadb \
--engine-version 10.2.39 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mariadb ^
--engine-version 10.2.39 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.

DescribeDBEngineVersions	
AutoUpgrade	EngineVersion
True	10.2.40
False	10.2.41
False	10.2.43
False	10.2.44
False	10.3.28
False	10.3.31
False	10.3.32
False	10.3.34
False	10.3.35
False	10.6.5
False	10.6.7
False	10.6.8

In this example, the AutoUpgrade value is True for MariaDB version 10.2.40. So, the automatic minor upgrade target is MariaDB version 10.2.40, which is highlighted in the output.

A MariaDB DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version \(p. 362\)](#).

Importing data into a MariaDB DB instance

You can use several different techniques to import data into an RDS for MariaDB DB instance. The best approach depends on the source of the data, the amount of data, and whether the import is done one time or is ongoing. If you are migrating an application along with the data, also consider the amount of downtime that you are willing to experience.

Find techniques to import data into an RDS for MariaDB DB instance in the following table.

Source	Amount of data	One time or ongoing	Application downtime	Technique	More information
Existing MariaDB DB instance	Any	One time or ongoing	Minimal	Create a read replica for ongoing replication. Promote the read replica for one-time creation of a new DB instance.	Working with read replicas (p. 370)
Existing MariaDB or MySQL database	Small	One time	Some	Copy the data directly to your MySQL DB instance using a command-line utility.	Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance (p. 1004)
Data not stored in an existing database	Medium	One time	Some	Create flat files and import them using the <code>mysqlimport</code> utility.	Importing data from any source to a MariaDB or MySQL DB instance (p. 1019)
Existing MariaDB or MySQL database on premises or on Amazon EC2	Any	Ongoing	Minimal	Configure replication with an existing MariaDB or MySQL database as the replication source. You can configure replication into a MariaDB DB instance using MariaDB global transaction identifiers (GTIDs) when the external instance is MariaDB version 10.0.24 or higher, or using binary log coordinates for MySQL instances or MariaDB instances on earlier versions than 10.0.24. MariaDB GTIDs are implemented differently than MySQL GTIDs, which aren't supported by Amazon RDS.	Configuring binary log file position replication with an external source instance (p. 1036) Importing data to an Amazon

Source	Amount of data	One time or ongoing	Application downtime	Technique	More information
					RDS MariaDB or MySQL DB instance with reduced downtime (p. 1006)
Any existing database	Any	One time or ongoing	Minimal	Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.	What is AWS Database Migration Service and Using a MySQL-compatible database as a target for AWS DMS in the AWS Database Migration Service User Guide

Note

The mysql system database contains authentication and authorization information required to log into your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the mysql database in your DB instance can result in errors and might render the DB instance and your data inaccessible. If this occurs, the DB instance can be restored from a snapshot using the AWS CLI [restore-db-instance-from-db-snapshot](#) or recovered using [restore-db-instance-to-point-in-time](#) commands.

Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance

You can also import data from an existing MariaDB or MySQL database to a MySQL or MariaDB DB instance. You do so by copying the database with [mysqldump](#) and piping it directly into the MariaDB or MySQL DB instance. The mysqldump command line utility is commonly used to make backups and transfer data from one MariaDB or MySQL server to another. It's included with MySQL and MariaDB client software.

Note

If you are using a MySQL DB instance and your scenario supports it, it's easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see [Restoring a backup into a MySQL DB instance \(p. 1361\)](#).

A typical mysqldump command to move data from an external database to an Amazon RDS DB instance looks similar to the following.

```
mysqldump -u local_user \
--databases database_name \
--single-transaction \
--compress \
--order-by-primary \
-plocal_password | mysql -u RDS_user \
--port=port_number \
--host=host_name \
-pRDS_password
```

Important

Make sure not to leave a space between the `-p` option and the entered password.

Make sure that you're aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the [pt-show-grants](#) utility.
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see [Controlling access with security groups \(p. 2085\)](#).

The parameters used are as follows:

- `-u local_user` – Use to specify a user name. In the first usage of this parameter, you specify the name of a user account on the local MariaDB or MySQL database identified by the `--databases` parameter.
- `--databases database_name` – Use to specify the name of the database on the local MariaDB or MySQL instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` is reading it, using this parameter helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.
- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `-plocal_password` – Use to specify a password. In the first usage of this parameter, you specify the password for the user account identified by the first `-u` parameter.
- `-u RDS_user` – Use to specify a user name. In the second usage of this parameter, you specify the name of a user account on the default database for the MariaDB or MySQL DB instance identified by the `--host` parameter.
- `--port port_number` – Use to specify the port for your MariaDB or MySQL DB instance. By default, this is 3306 unless you changed the value when creating the instance.
- `--host host_name` – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.
- `-pRDS_password` – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second `-u` parameter.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when

you run `mysqldump`. To do so, include the following parameters with your `mysqldump` command: `--routines=0 --triggers=0 --events=0`.

The following example copies the `world` sample database on the local host to a MySQL DB instance.

For Linux, macOS, or Unix:

```
sudo mysqldump -u localuser \
    --databases world \
    --single-transaction \
    --compress \
    --order-by-primary \
    --routines=0 \
    --triggers=0 \
    --events=0 \
    -plocalpassword | mysql -u rdsuser \
    --port=3306 \
    --host=myinstance.123456789012.us-east-1.rds.amazonaws.com \
    -prdspassword
```

For Windows, run the following command in a command prompt that has been opened by right-clicking **Command Prompt** on the Windows programs menu and choosing **Run as administrator**:

```
mysqldump -u localuser ^
    --databases world ^
    --single-transaction ^
    --compress ^
    --order-by-primary ^
    --routines=0 ^
    --triggers=0 ^
    --events=0 ^
    -plocalpassword | mysql -u rdsuser ^
    --port=3306 ^
    --host=myinstance.123456789012.us-east-1.rds.amazonaws.com ^
    -prdspassword
```

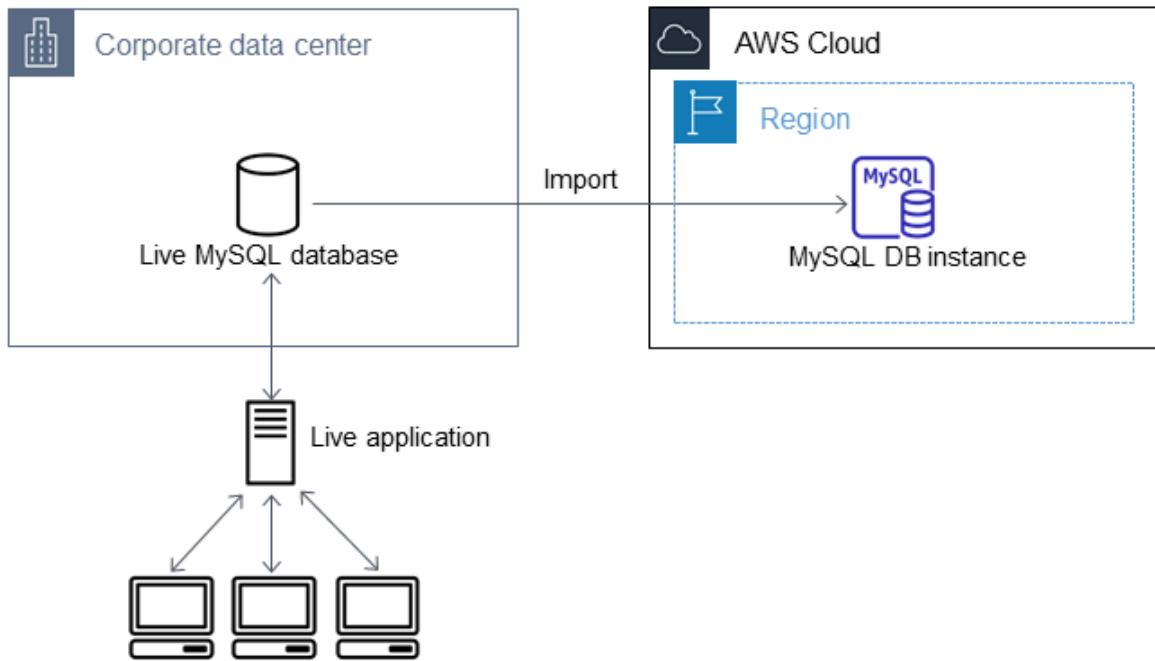

Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime

In some cases, you might need to import data from an external MariaDB or MySQL database that supports a live application to a MariaDB or MySQL DB instance. In these cases, you can use the following procedure to minimize the impact on application availability. This procedure can also help if you are working with a very large database. Here, the procedure helps because you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS DB instance. You then use replication to bring the Amazon RDS DB instance up-to-date with your live external instance, before redirecting your application to the Amazon RDS DB instance. You configure MariaDB replication based on global transaction identifiers (GTIDs) if the external instance is MariaDB 10.0.24 or higher and the target instance is RDS for MariaDB. Otherwise, you configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it due to its enhanced crash-safety features. For more information, see [Global transaction ID](#) in the MariaDB documentation.

Note

If you want to import data into a MySQL DB instance and your scenario supports it, it is easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see [Restoring a backup into a MySQL DB instance \(p. 1361\)](#).

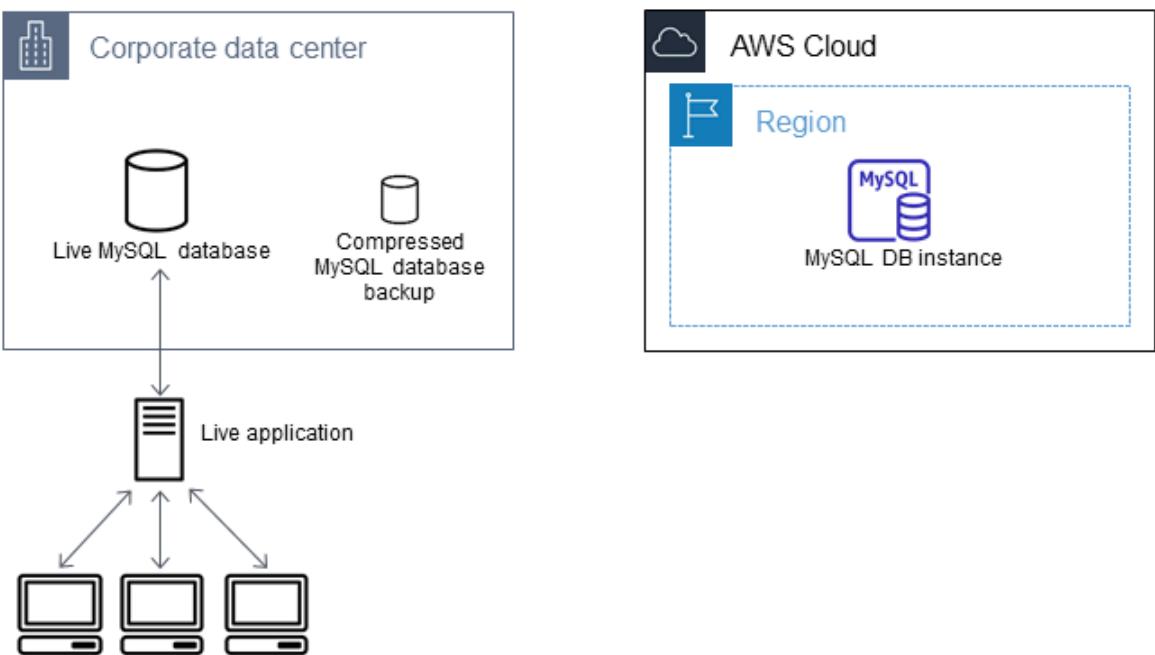

Note

We don't recommend that you use this procedure with source MySQL databases from MySQL versions earlier than version 5.5, due to potential replication issues. For more information, see [Replication compatibility between MySQL versions](#) in the MySQL documentation.

Create a copy of your existing database

The first step in the process of migrating a large amount of data to an Amazon RDS MariaDB or MySQL DB instance with minimal downtime is to create a copy of the source data.

You can use the mysqldump utility to create a database backup in either SQL or delimited-text format. We recommend that you do a test run with each format in a nonproduction environment to see which method minimizes the amount of time that mysqldump runs.

We also recommend that you weigh mysqldump performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the `LOAD DATA LOCAL INFILE` command. For more information about choosing a mysqldump format and then loading the data, see [Using mysqldump for backups](#) in the MySQL documentation.

Before you start the backup operation, make sure to set the replication options on the MariaDB or MySQL database that you are copying to Amazon RDS. The replication options include turning on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

Note

Use the `--single-transaction` option with mysqldump because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL) statements while mysqldump is running. You can schedule a maintenance window for these operations.

Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The mysqldump utility excludes these schemas by default.

To migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the [pt-show-grants](#) utility.

To set replication options

1. Edit the `my.cnf` file (this file is usually under `/etc`).

```
sudo vi /etc/my.cnf
```

Add the `log_bin` and `server_id` options to the `[mysqld]` section. The `log_bin` option provides a file name identifier for binary log files. The `server_id` option provides a unique identifier for the server in source-replica relationships.

The following example shows the updated `[mysqld]` section of a `my.cnf` file.

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

For more information, see [the MySQL documentation](#).

2. Restart the `mysql` service.

```
sudo service mysqld restart
```

To create a backup copy of your existing database

1. Create a backup of your data using the mysqldump utility, specifying either SQL or delimited-text format.

Specify `--master-data=2` to create a backup file that can be used to start replication between servers. For more information, see the [mysqldump](#) documentation.

To improve performance and ensure data integrity, use the `--order-by-primary` and `--single-transaction` options of mysqldump.

To avoid including the MySQL system database in the backup, do not use the `--all-databases` option with mysqldump. For more information, see [Creating a data snapshot using mysqldump](#) in the MySQL documentation.

Use `chmod` if necessary to make sure that the directory where the backup file is being created is writeable.

Important

On Windows, run the command window as an administrator.

- To produce SQL output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump \  
  --databases database_name \  
  --master-data=2 \  
  --single-transaction \  
  --order-by-primary \  
  -r backup.sql \  
  -u local_user \  
  -p password
```

For Windows:

```
mysqldump ^  
  --databases database_name ^  
  --master-data=2 ^  
  --single-transaction ^  
  --order-by-primary ^  
  -r backup.sql ^  
  -u local_user ^  
  -p password
```

- To produce delimited-text output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump \  
  --tab=target_directory \  
  --fields-terminated-by ',' ' \  
  --fields-enclosed-by '"' ' \  
  --lines-terminated-by 0x0d0a \  
  database_name \  
  --master-data=2 \  
  --single-transaction \  
  --order-by-primary \  
  -p password
```

For Windows:

```
mysqldump ^  
  --tab=target_directory ^  
  --fields-terminated-by "," ^  
  --fields-enclosed-by "" " ^  
  --lines-terminated-by 0x0d0a ^  
  database_name ^
```

```
--master-data=2 ^  
--single-transaction ^  
--order-by-primary ^  
-p password
```

Note

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, exclude them when you run mysqldump. To do so, include the following arguments with your mysqldump command: `--routines=0 --triggers=0 --events=0`.

When using the delimited-text format, a CHANGE MASTER TO comment is returned when you run mysqldump. This comment contains the master log file name and position. If the external instance is other than MariaDB version 10.0.24 or higher, note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`. You need these values when setting up replication.

```
-- Position to start replication or point-in-time recovery from  
--  
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you are using SQL format, you can get the master log file name and position in the CHANGE MASTER TO comment in the backup file. If the external instance is MariaDB version 10.0.24 or higher, you can get the GTID in the next step.

2. If the external instance you are using is MariaDB version 10.0.24 or higher, you use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

```
SELECT BINLOG_GTID_POS('binary log file name', binary log file position);
```

Note the GTID returned; you need it to configure replication.

3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS DB instance. Take note of the size of the backup file; you need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

- To compress SQL output, use the following command.

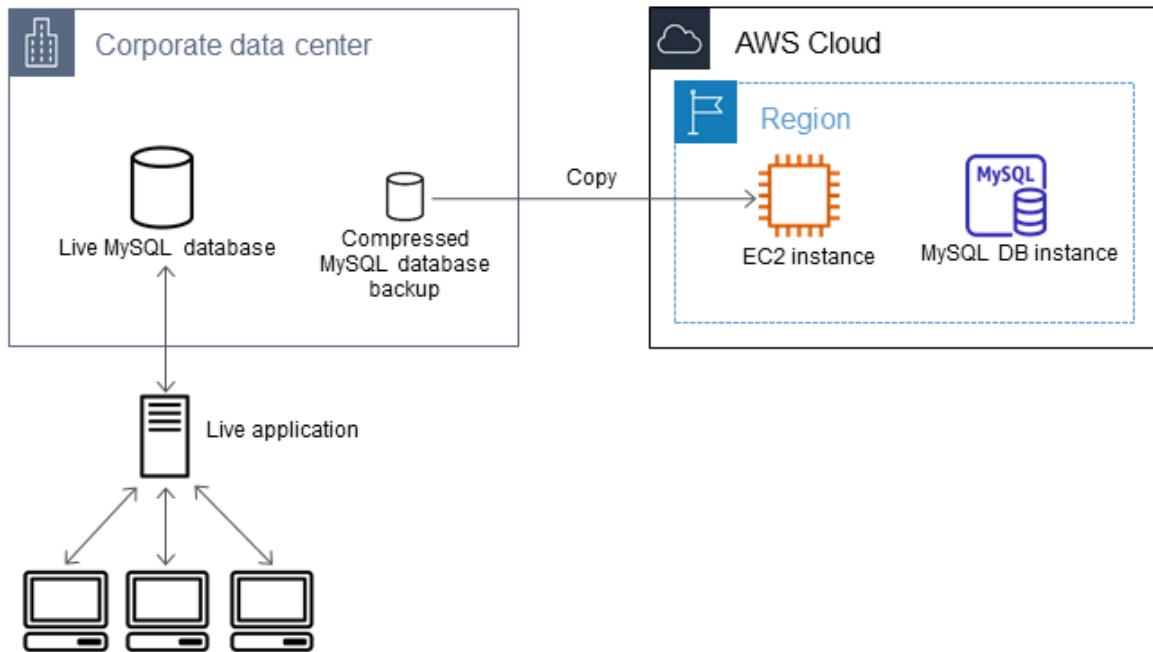

```
gzip backup.sql
```

- To compress delimited-text output, use the following command.

```
tar -zcvf backup.tar.gz target_directory
```

Create an Amazon EC2 instance and copy the compressed database

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MariaDB or MySQL DB instance. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS DB instance also reduces network latency during the import.

To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the RDS DB instance to run your MySQL database engine, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. This can be a range of IP addresses (for example, 203 . 0 . 113 . 0/24), or another VPC security group. You can use the [Amazon VPC Management Console](#) to create and manage VPCs, subnets, and security groups. For more information, see [Getting started with Amazon VPC](#) in the *Amazon Virtual Private Cloud Getting Started Guide*.
2. Open the [Amazon EC2 Management Console](#) and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS DB instance. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see [Getting started with Amazon EC2 Linux instances](#) in the *Amazon Elastic Compute Cloud User Guide for Linux*.
3. To connect to your Amazon RDS DB instance from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the **Details** tab of the **Instance** pane in the EC2 console window. To edit the VPC security group and add an inbound rule, choose **Security Groups** in the EC2 console navigation pane, choose your security group, and then add an inbound rule for MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see [Adding and removing rules](#) in the *Amazon VPC User Guide*.
4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use chmod if necessary to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use scp or a Secure Shell (SSH) client to copy the file. The following is an example.

```
$ scp -r -i key_pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/backup.sql.gz
```

Important

Be sure to copy sensitive data using a secure network transfer protocol.

5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands.

```
sudo yum update -y  
sudo yum install mysql -y
```

For more information, see [Connect to your instance](#) in the *Amazon Elastic Compute Cloud User Guide for Linux*.

Important

This example installs the MySQL client on an Amazon Machine Image (AMI) for an Amazon Linux distribution. To install the MySQL client on a different distribution, such as Ubuntu or RedHat Enterprise Linux, this example doesn't work. For information about installing MySQL, see [Installing and Upgrading MySQL](#) in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following are examples.

- To decompress SQL output, use the following command.

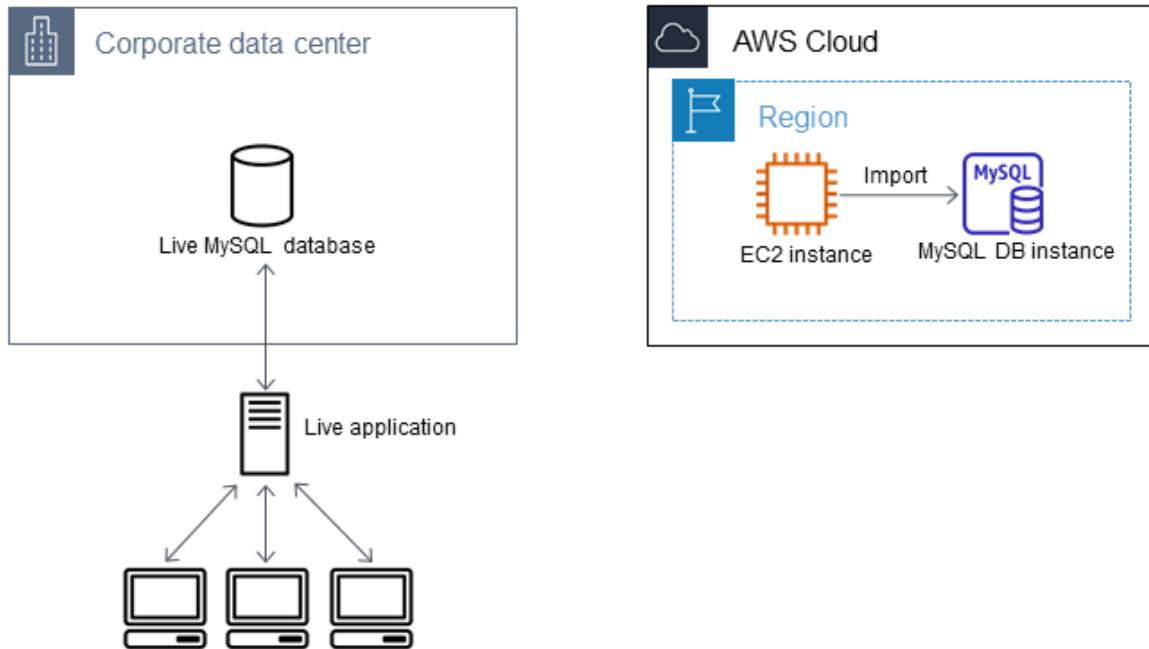

```
gzip backup.sql.gz -d
```

- To decompress delimited-text output, use the following command.

```
tar xzvf backup.tar.gz
```

Create a MySQL or MariaDB DB instance and import data from your Amazon EC2 instance

By creating a MariaDB or MySQL DB instance in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from EC2 faster than over the internet.

To create a MariaDB or MySQL DB instance and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS DB instance. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MariaDB or MySQL database. For more information, see [DB instance classes \(p. 10\)](#).
2. Determine if Amazon RDS provisioned I/O operations per second (IOPS) is required to support the workloads. Provisioned IOPS storage delivers fast throughput for online transaction processing (OLTP) workloads, which are I/O intensive. For more information, see [Provisioned IOPS SSD storage \(p. 66\)](#).
3. Open the [Amazon RDS console](#). In the upper-right corner, choose the AWS Region that contains your Amazon EC2 instance.
4. In the navigation pane, choose **Databases**.
5. Choose **Create database**, and then go through the steps to choose options for your DB instance:
 - a. Make sure that **Standard Create** is chosen.
 - b. In the **Engine options** section, choose **MySQL** or **MariaDB**, as appropriate.
 - c. For **Version**, choose the version that is compatible with your source MySQL instance, as follows:
 - If your source instance is MySQL 5.5.x, the Amazon RDS DB instance must be MySQL.
 - If your source instance is MySQL 5.6.x or 5.7.x, the Amazon RDS DB instance must be MySQL or MariaDB.
 - If your source instance is MySQL 8.0.x, the Amazon RDS DB instance must be MySQL 8.0.x.
 - If your source instance is MariaDB 5.5 or higher, the Amazon RDS DB instance must be MariaDB.
 - d. In the **Templates** section, choose **Dev/Test** to skip configuring Multi-AZ deployment and provisioned IOPS storage.
 - e. In the **Settings** section, specify the requested **DB instance identifier** and user information.
 - f. In the **DB instance class** and **Storage** sections, specify the DB instance class and allocated storage size that you want.
 - g. In the **Availability & durability** section, choose **Do not create a standby instance for Multi-AZ deployment**.
 - h. In the **Connectivity** section, choose the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Set **Publicly accessible** to **Yes**. To set up replication with your source database as described later, your DB instance must be publicly accessible.

Use the default values for the other settings in this section.

In the **Backup** section, set the backup retention period to **0 days**.

Use the default values for the other settings in this section.

- i. Open the **Additional configuration** section, and specify an **Initial database name**.

Set the **Backup retention period** to **0 days**

Use the default values for the other settings in this section.

- j. Choose **Create database**.

Your new DB instance appears in the **Databases** list with the status **Creating**. Wait for the **Status** of your new DB instance to show as **Available**.

Don't configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is done, you can set Multi-AZ and backup retention the way that you want them for the production instance. For a detailed walkthrough of creating a DB instance, see [Creating an Amazon RDS DB instance \(p. 230\)](#).

6. Review the default configuration options for the Amazon RDS DB instance. In the RDS console navigation pane, choose **Parameter groups**, and then choose the magnifying glass icon next to the **default.mysqlx.x** or **default.mariadb.x** parameter group. If this parameter group doesn't have the configuration options that you want, find a different one that does or create a new parameter group. For more information on creating a parameter group, see [Working with parameter groups \(p. 289\)](#).
